The friars were conscientious chroniclers of Mesoamerican culture and they have left us many long and absorbing accounts of Indian life and of the New World that they were the first to study. But about the sacred mushrooms they are sparing of words or, as in the famous Badianus manuscript, silent. Nor are the inebriating mushrooms even mentioned (contrary to what the title would lead one to expect) in *Problemas y Secretos Maravillosos de las Indias*, by Juan de Cárdenas, published in 1591 in Mexico. The best of the churchmen are neutral, but all their testimony is hearsay sometimes mixed with prejudice: they neither ingested them nor witnessed their ingestion, if we judge by their writings. The testimony of their informants, insofar as we possess it, must be read with caution: the witnesses used by Bernardino de Sahagún were the most honorable, intelligent, and well informed natives that could be found and they occupied a privileged position with the friars that they would fain keep. They knew what the friars would have them say about the entheogens. When these informants testify in Nahuatl about the mushrooms, their words occasionally disclose an embarrassing torque between, on the one hand, what the friars expected them to say and, on the other, their strong leaning in favor of the truth: but their words always wind up on the side of the friars.

Another source of information lies in the Proceedings of the Holy Office of the Inquisition, now housed in the Archivo General de la Nación: for the sixteenth and seventeenth centuries they give us a taste of what was happening in the humble homes of the *indigenas*, as the Indians are called today, of *mestizo* families, and in that part of the creole world living in intimacy with the *indigenas*. The coverage of the Inquisition was spotty, as one would expect, but would have permitted an historian of imagination to surmise the truth. We now know, thanks to our own soundings of the Indian world in the highlands of the States of Oaxaca, Puebla, Veracruz, and Mexico, and thanks also to the mycologists, anthropologists, and linguists who have followed our trail, how widespread and firm a hold until recent times the mushrooms have had on the imaginations and practices of the indigenous world of monoglot Indians. The public celebrations of pre-Conquest times are long since gone for good, but the midnight *veladas* continue even now in lowly homes, in *rancherias*, a major feature in the lives of the Indians. They continue today, but as the country is fast opening up, this unique survival of a practice going back to the Stone Age is disappearing.

The Indians of Mesoamerica, as I have said, discovered the amazing properties of the entheogenic mushrooms. The friars learned of them from the Indians and tell us a little about them by hearsay. They were re-discovered in our times by a dramatic event: a United States Government botanist of established reputation, William E. Safford, on 4 May 1915 in a formal address delivered before the Botanical Society of Washington, D. C., said that he had searched for inebriating mushrooms and found none. As was not uncommon in those days in botanical and ethnological circles, he was contemptuous of the herbal knowledge of the Indians and said they had confused the dried cactus peyote (*Lophophora Williamsii*) buttons with mushrooms. (It is the fate of some worthy scientists and scholars to be remembered for the blunders they make.) Later in that year his address was published, lavishly illustrated and documented, with the express approval of the Department of Agriculture, in the *Journal of Heredity*. Most of those who listened to him or read him learned of the supposed existence of inebriating mushrooms only to learn in the same breath that they had never really existed. His paper was a major effort on his part, but contrary to his expectation, some time later a still small voice of an obscure ethnobotanist in Mexico, Blas Pablo Reko, made itself heard, faintly, persistently, protesting that the mushrooms were still being used in the State of Oaxaca, and little by little other voices joined his - Robert J. Weitlaner, Jean Bassett Johnson, and the Harvard botanist Richard Evans Schultes. In 1938 Schultes took back to Harvard from Huautla de Jiménez specimens of the mushrooms and Johnson with his companions succeeded in enlisting a shaman for a midnight session. This session turned out to be one where grains of corn were used for divination. There was no singing and the mushrooms were ingested by the shaman alone.

---

[1] At the time of the Conquest Mesoamerica was dominated by the Nahua, native speakers of the Nahuatl language, the *lingua franca* of the area, and the Nahua were dominated in turn by the Nahuatl-speaking Aztecs living in an island city in the Valley of Mexico called Tenochtitlan, now known as Mexico City. The prestige of the Nahua ran far beyond the confines of Mesoamerica. The distinguished Ojibway Keewaydinoquay calls my attention to an Ojibway legend that starts with these ringing words:

> Mewija shabwasong Nahuwahinawinnini... Long long ago, far away to the South, in the land of the people called Nahua...

The Ojibway are an Algonkian people living in the Great Lakes area. Until I told her Kee had never known who the Nahua were.

World War II broke out. All thought of the mushrooms dried up until Valentina Pavlovna and I, approaching the subject from a far different angle, turned up in Huautla in the middle 1950's. We had been alerted by two articles that Schultes had published following his field trip, by the pencil sketch of a 'mushroom stone' that our printer Giovanni Mardersteig had found in the Rietberg Museum of Zurich, and later by an extraordinary letter written to us by Eunice V. Pike, a Protestant missionary to the Mazatecs.

And so it came about that Safford's resounding blast in 1915 served as the catalyst that triggered the investigation among our ethnobotanists, starting Mesoamerican studies on their way to a just appraisal of the part played by the entheogenic mushrooms in pre-Conquest history.

In 1971 Benjamin Keen published his The Aztec Image in Western Thought in which he presented, in a fascinating way, the attitude of successive generations and of different segments of each generation toward the Aztec civilization. He mentions the 'magical mushrooms' only once in 600 pages and they are not even cited in his index. Keen was right: the mushrooms have played no part in the world's appraisal of Mesoamerican culture. In the first instance the Catholic clergy were responsible for playing down and misrepresenting this major element in the complex pattern of Mesoamerican life. But I believe the mushrooms were ignored for an additional reason: the deep-seated mycophobic strain in the West-European elements that have studied or observed the Nahuatl culture, a latent mycophobia, a subliminal rejection, that runs through much of Western civilization and that dates from a time in prehistory when the cult of assorted entheogenic mushroom species was superseded by other religious foci and ultimately by the Christian religion. I only cite this as a possibility here but will return to the theme later.

When we first went down to Mexico in 1953, we felt certain, my wife and I, that we were on the trail of an ancient and holy Mystery and we went as pilgrims seeking the Grail. To this attitude of ours I attribute such success as we have had. It was not easy. For four and a half centuries the rulers of Mexico, men of Spanish blood or at least of Spanish culture, have never entered sympathetically into the ways of the Indians, and the Church regarded the worship of the sacred mushroom as an idolatry. The Protestant missionaries of today are naturally intent on carrying the Gospel to the Indians, not on absorbing the religion of the Indians. Nor are most Mesoamerican anthropologists good at this sort of thing. Their frequent failure to enter into the religious life of the peoples they study, their frequent inability to cope with the higher reaches of the cultures that absorb their attention, reveal a disconcerting lacuna in their work, an anthropological fact about the anthropologists that should alert the rest of us.[2]

For more than four centuries the Indians have kept the divine mushroom close to their hearts, sheltering it from desecration by white men, a precious secret. We know that today there are many shamans who carry on the cult, each according to his lights, some of them consummate artists, performing the ancient liturgy in remote dwellings before minuscule congregations. With the passing years they will die off, and, as the country opens up, the cult is destined to disappear. They are hard to reach, these shamans. Almost invariably they speak little or no Spanish. To them, performing before strangers seems a profanation. They will refuse to meet with you, much less discuss the beliefs that go with the mushrooms and perform for you. Perhaps you will learn the names of a number of renowned shamans and your emissaries will even promise to deliver them to you, but then you wait and wait and they never come. You will brush past them in the marketplace and they will know you but you will not know them. The cobbler across the way may be the very man you are seeking: you may pass the time of day with him, yet never learn that he is the shaman you need. In the writings on shamanism I have never seen mentioned this reluctance of the gifted shamans to perform before outsiders. Yet it seems unlikely that such reluctance is confined to the mountains of Oaxaca, for it is the natural response of a believing religious leader to the importunities of non-believers and thrill-mongers. A Catholic priest will scorn to say Mass expressly to satisfy the curiosity of non-believers. In some accounts of shamanic performances held in various parts of the world I have asked myself what category of shaman we are dealing with: they behave like the charlatans in Huautla, eager to perform for outsiders but who are *embusteros*, *farsantes*, frauds. They have leaped into existence to meet the demands of the visitors following in our trail. The true shaman believes in the mushrooms, believes in himself, and believes in the handful of poor Indians who constitute his following.

---

[2] I. M. Lewis, Professor of Anthropology in the London School of Economics, draws attention also to the frequent inability of anthropologists to sense the religious aspect of the people they are studying; see *Ecstatic Religion*, a Pelican book published in London by Penguin Books in 1971, p. 14 and later. Similarly, P. Gelling and Hilda Ellis Davidson: *The Chariot of the Sun*, pp 5-6, J. M. Dent Sons, Ltd, 1969.

The genuine shamans, as I have said, shun contact with strangers. But this is not so with the 'laymen', especially the elderly men and women of a village. They do not initiate a conversation with you about the mushrooms. But after you have made a good impression on them and won their confidence, then late in the evening, by the light of a fire and *velas*, if you bring the conversation around to the sacred mushrooms, it is astonishing how freely they discuss them, how they will stay up late full of the subject, and how glad they are to meet a stranger who shows a sympathetic and lively interest in the miraculous 'little things'. Though Sahagún and many other sixteenth century friars gave leads aplenty, our anthropologists have traditionally shown no curiosity about them.

Not that the shamanism as practiced in Oaxaca has been unaffected by four centuries and more of contact with Christianity: Catholic elements blend with the pagan mushroom rite and the Indians see no incompatibility. María Sabina, our now famous shaman, sings chants that are full of Christian locutions - names of saints, the Lord's Prayer in Spanish that she has learned by rote, *etc*. These Christian locutions in her singing jostle with the forces of nature, with professions of humility, and later in the session with bold assertions of her authority. The mushrooms are the 'dear little children', *ˀnti*^{1}*xti*^{3}, the 'clowns', *sa*^{4}*se*^{1}, but at the climax of the *velada* they pronounce dread judgement with the voice of Jesus Christ![3] The synthesis is complete. When I have been present she has always begun her performance with a cheap chroma of the *Santo Niño*, the 'Holy Child', on the altar in front of her. But when she has inverted a flower over the last wick and thus extinguished it, from then on the proceedings take place, pagan-fashion, on the floor, the habitual practice of the American Indian. We are now in darkness. There can be no question: her verses come down to her from a rite that Ruiz de Alarcon reported to us in the early seventeenth century and of necessity, her singing and the verses being inseparable, her music dates also from the same remote period. They are of great antiquity, pre-Cartesian, going back surely for millennia.[4]

María Sabina, herself an eminent shaman of the mushroom rite, is a church member in good standing. She has belonged to the Asociación del Sagrado Corazón de Jesús, and has been not only a member - *socia* - but a captain of ten, a *celadora*. The Church has ceased to fight the mushrooms. It is even rumored, perhaps falsely, that in some remote parishes the priest himself has officiated at the mushroom rite. It was not always so. In the sixteenth and seventeenth centuries, when the secular arm placed itself at the disposal of the Church, the Inquisition saw to it that those who used the mushrooms suffered the harsh rigors of the law. Curiously, the Church did not dispute the efficacy of the mushrooms, their capacity to reveal the truth. But the Church said the mushrooms were the Devil's minions and so the idolatrous practices invoking them had to be extirpated.

---

[3] Mazatec is a tonal language with 4 tones, ^{1} being the highest. There are also glides from one tone to another, the glides being represented by two or, rarely, three digits. 'ˀ' represents a glottal stop, as in the Scottish pronunciation *bott'l*.

[4] See *María Sabina and Her Mazatec Mushroom Velada*, by Wasson *et al*., Harcourt Brace Jovanovich, Inc., New York, 1974; pp XXV ff. In the Zapotec country on the Pacific Coast, far removed from Huautla, speaking of Aristeo Matías, the shaman, in 1957 I wrote: 'His chanting was low and feeble, and of course in Zapotec, but I had the impression that his singing was identical to what the Señora had sung with magisterial authority in the Mazatec country.' *Mushrooms Russia & History*, p. 314. The Zapotec and Mazatec languages are perhaps unrelated, and if related, only most distantly so.

To win the confidence of the Indians and to gain access to a superior shamanic performance one must possess two qualities in high degree: patience and tact, and then in addition a bountiful measure of luck. Our first stroke of fortune was winning the cooperation of the late Robert J. Weitlaner, Austrian-born engineer who gave up that profession to study the Indians. He led us by the hand on our first excursion on muleback into the Sierra Mazateca and later he accompanied us on many other explorations. For ten years we had repeated recourse to him, tapping his immense knowledge of the Indians, their ways, their languages, their history. His patience, good humor, and *joie de vivre*, in the sierra sierra and in Mexico City, were unfailing. But above all else we learned from him how to handle ourselves with the Indian. The Indians are simply living by the conventions of an orally transmitted culture such as our own forebears lived by not so long ago - not long ago as compared with the long stretch of time that our ancestors have been on the earth. When you visit the Indian villages you make allowances for this time lag. You do not treat them as inferiors or children. You do not treat them kindly *as though* they were equals. (The Indians are quick to see through you.) Weitlaner taught us to treat the Indians as equals: a secret simple yet elusive. As the poet said, truly 'this is the famous stone that turneth all to gold'.

I am repeatedly asked what the future holds for our entheogenic mushrooms and the other entheogens. My interest being in proto-history and Early Man, this question is beyond the scope of my inquiry. Whether chemists and therapists will find some lasting use for the extraordinary substances that we have discovered in these strange plants, I will not predict. Today we know, as Early Man did not, that the active agents are certain chemicals with a precisely defined molecular structure. Early Man thought they were miracle plants that spoke to him with the voice of God. In these times we cannot accept this, though there is a possibility that these chemicals in some way unlock the door to extrasensory perception in some people. The awe and reverence that these plants once evoked seem to me gone for good. Their utilization for 'recreation' is, certainly, a passing fad. The world offers too many opportunities for exciting explorations and discoveries to justify any such activity on a large and lasting scale.

More than fifty years have passed since Valentina Pavlovna and I started on mushrooms. She was a Russian, a Muscovite, and a practicing pediatrician in New York. I began life as a newspaper man and after almost ten years switched to banking, where I stayed for more than thirty-five years, retiring for age on 30 June 1963. Neither of us was qualified in any of the disciplines that the pursuit of our avocation called for. Neither of us was a mycologist nor even a botanist, nor archæologist, nor anthropologist, nor folklorist, nor in the technical sense a linguist, nor had we made of literature or history any special study. I suppose most persons would call us deeply religious, though we did not really adhere to any creed. She was a member of the Russian Orthodox Church and I am an Episcopalian, my father having been a minister. We began our inquiries among our friends and almost before we knew it our circle of friends began to expand. As questions arose we directed them, at first by letter, to those best qualified to answer them, and on our far-ranging travels we sought the acquaintance of those who seemed to be promising sources of information. This we did with unremitting zeal. Many of our new friends were academicians, others were amateurs in the original meaning of that word, but many were humble people often unlettered and these included some of our most valued informants: one of these was a Slovak, a cleaning man in my bank, who opened the doors for me to the Slovakian mushroom vocabulary, my excellent friend Nicholas Kazenchak. My wife died on 31 December 1958 late in the evening and after her death I carried on alone.

In this book the attentive reader will observe that I avoid certain words commonly used in treating our subject. We do not call the entheogens 'narcotics': the etymology from 'narcosis', sleep, is so obvious that the word is inappropriate and misleading for substances that keep one, willy-nilly, wide awake. We refrain from using 'witch doctor', a denigrating term for the herbalist who in his day knew the plant world well and has taught our medical profession many secrets, some of major importance. Nor do I speak of the peoples who are my subject as 'barbarians' or 'savages', as used to be our wont, epithets of contempt that ill become anyone in our day to apply to other peoples. We of the twentieth century have earned a prior lien on those titles of dishonor.

I cannot even guess how many advisers and informants we have had. If we have contributed something to man's understanding of his past, we may fairly say, I think, that this is due to our not being specialists and to our faculty for tapping information from all sources, of low and high degree. We often said to each other that we were only *rapporteurs* digesting as best we could what our sources had to say. Naturally there are half a dozen counsellors who loom large in our thinking, who indeed were indispensable to us in making headway. Conspicuous among them is Roger Heim to whom this book is dedicated.

What guardian angel had me in his keeping when, after the Second World War, I ascended the steps of Professor Heim's laboratory in Paris to meet him for the first time, a stranger, an American, an ignoramus in the intricate, the vast, the exacting discipline that was his! At once he made me feel at home and soon he came to share our enthusiasm for ethnomycological inquiries. (At that time we had no inkling of our future Mexican discoveries.) With Valentina Pavlovna and our daughter Masha, in the early '50's, we made an excursion together to Serignan near Orange in the Rhone Valley, to the home of Henri Fabre (his '*harmas*') where we selected the Fabre watercolors that we reproduced with infinite care in *Mushrooms Russia & History*. Roger Heim was electrified by our discoveries in the seasons 1953, 1954, and 1955 in Mexico and he accepted at once my suggestion that he join us on field trips to the Mazatec country, the Mixeria, and the Chatino enclave in 1956, 1959, and 1961. When we brought out early in 1959 our joint work, *Les Champignons hallucinogènes du Mexique*, it was he who, without my knowledge, dedicated it to the memory of Valentina Pavlovna, and who in its pages and also in his *Revue de Mycologie* carried to a successful conclusion a minor but vexatious mycological polemic that threatened to disturb the even tenor of our work. Later, again on my initiative, we made two extraordinarily fruitful field trips, one to the Kumá people below Mount Hagen in New Guinea in 1963 and the other in 1967 to the Simlipal Hills and thereabouts in Orissa (India) and the Santal Parganas in Bihar. Altogether our trips, our thick files of correspondence, our many publications vastly enriched Valentina Pavlovna's life and mine.

For upwards of forty years Roger Heim was the chief in Paris of the Laboratoire de Cryptogamie and the editor of the *Revue de Mycologie*. From 1951 to 1965 he also bore the burden of the direction of the Muséum National d'Histoire Naturelle, that renowned center for advanced teaching and research in biological studies, one of the glories of French culture, and for a term he was also Président of the Académie des Sciences. But these titles to academic distinction, though themselves of the highest order, do not tell the whole story. Vast as is his learning and experience in field and laboratory, sound as is his judgement in the vexed problems that beset mycologists, formidable as he is in polemic, it is as a rare human being that I best remember him. Patient with the beginner, inspiring as a teacher, model of generosity toward others, prodigious worker, classical stylist in the French language, who could be more delightful whether in his published writings, or in his correspondence, or as a companion in the field? In the presence of Roger Heim, the timeworn conflict between science and the humanities fades away. One senses that the field of science for him is merely the New World that civilized man, the exponent of the humanities, is exploring and assimilating. It is an honor for me to be privileged to record thus publicly our debt to this beloved friend, this distinguished French scientist and Academician.

★

Chapter 1 tells the story of the all-night shamanic vigil of Mesoamerica where the divine mushrooms (or other entheogens) are 'consulted'. I have often told what happens at these *veladas* and for some of my readers this covers ground more or less familiar, but Chapter 2 dealing with the traits of the *velada* and kindred topics is largely new. Here I begin to present a fresh interpretation of the rôle of the entheogenic mushrooms in the life of the Mesoamerican Indians before and after the Conquest. I have relied heavily on the detailed studies of specialists, many of which, in the past twenty years, have revealed telling evidence, linguistic, archæological, anthropological. It seems to me that a common denominator unites these studies, a common denominator overlooked by the scholars who have not seen the wood for the trees. But they have supplied the indispensable components for the portrait that I offer of mycolatry in Mesoamerica, and I seize this opportunity to express my boundless gratitude to each of them. They alone have made this book possible.

My argument is many-faceted. I treat one facet in each chapter and each chapter is complete in itself. But this means that occasionally, for the reader's convenience, the same evidence is repeated in the new context. I repeat the evidence and remind the reader that it has appeared before. The 'Consulted Texts', beginning on p 231, consist of sources actually used and quoted in my book and, to reduce the footnotes, I have added to the entries therein the pages that I cite without precise source in the text.

The following abbreviations, familiar to all students of Mexico's past, occur from time to time in our text and often in the 'Consulted Texts':

AGN: Archivos Generales de la Nación
INAH: Instituto Nacional de Antropología e Historia
INI: Instituto Nacional Indígenista
UNAM: Universidad Nacional Autónoma de México

Honorary Research Fellow, Botanical Museum, Harvard University
Honorary Research Associate, New York Botanical Garden

The Present

CHAPTER 1
A *Velada* in Huautla

My first encounter with María Sabina was on Wednesday 29 June 1955, late in the afternoon. Allan Richardson, my friend and photographer, and I had arrived in Huautla the day before and Valentina Pavlovna with our daughter, Masha, was expected toward the end of the week. It was my third trip to Mexico in quest of the sacred mushrooms and our second visit to Huautla. Before noon I made my way down the steep, rough alleys to the town hall, called in Mexico the *municipio*. Unsuccessful in finding any first class shaman who would talk with us, much less celebrate the rite for us, I was increasingly impatient. I was even willing to present myself to the town officials, and if they seemed propitious, to solicit their help. I found only one man in the bare barn-like loft that served as the office of the *Presidente*: a man about thirty-five years old, athletic, with a genial, outgoing, honest smile. He was the *síndico* of the town, the No 2 man, Cayetano García Mendoza, now acting *Presidente* in the absence of his chief. After we had exchanged greetings, we discussed the outlook for the maize crop, the prices of coffee. Then and there, encouraged by the frankness of this excellent man, I made up my mind to put to him the vital question. (I had been cautioned never to consort with town officials: they are often a bad lot, sly, self-seeking, sometimes downright dishonest or unfriendly.) I leaned over the table and in a low voice said, 'May I take you into my confidence?' At once he was all curiosity, his face suddenly grave. 'Will you help me to learn the secrets of the *ˀnti*^{1}*xi*^{3}*tjo*^{3}?' I remember the way he threw his arms back in surprise at the question and at my knowing the Mazatec word for the sacred mushrooms. Without hesitating he said that nothing was easier, and to come to his house at the hour of the siesta. He lived at the other end of town, called *el Plan de la Salida*, about a mile away. Later, when I joined Allan Richardson, he was as excited as I at the possibility that, finally, we were to make a break-through.

Fig 3 Map of Mazatec country. The villages shown are those named in our text

A little after 4 o'clock Allan and I found Cayetano at home reclining in his hammock and taking his ease. Cayetano's house opens directly on the village thoroughfare running along the mountain side. You enter on the upper level from the road, and then inside the house, by a small trap-door in one corner, you make your way down a steep and twisting stairway to the floor below, where the events that we are about to relate took place. (See chart, Fig 5)

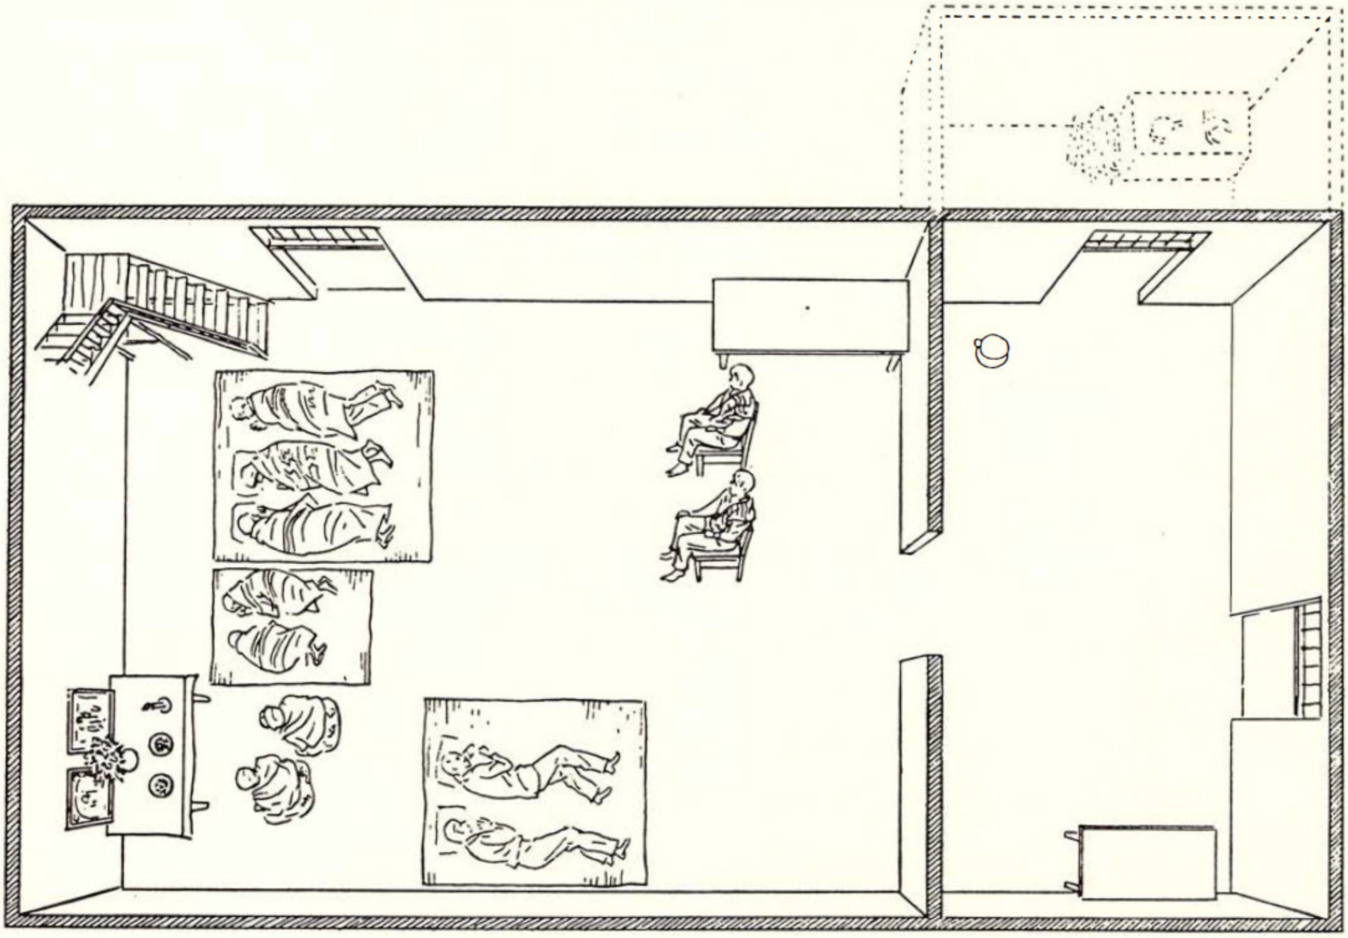

Fig 5 Chart of the room where the *velada* took place

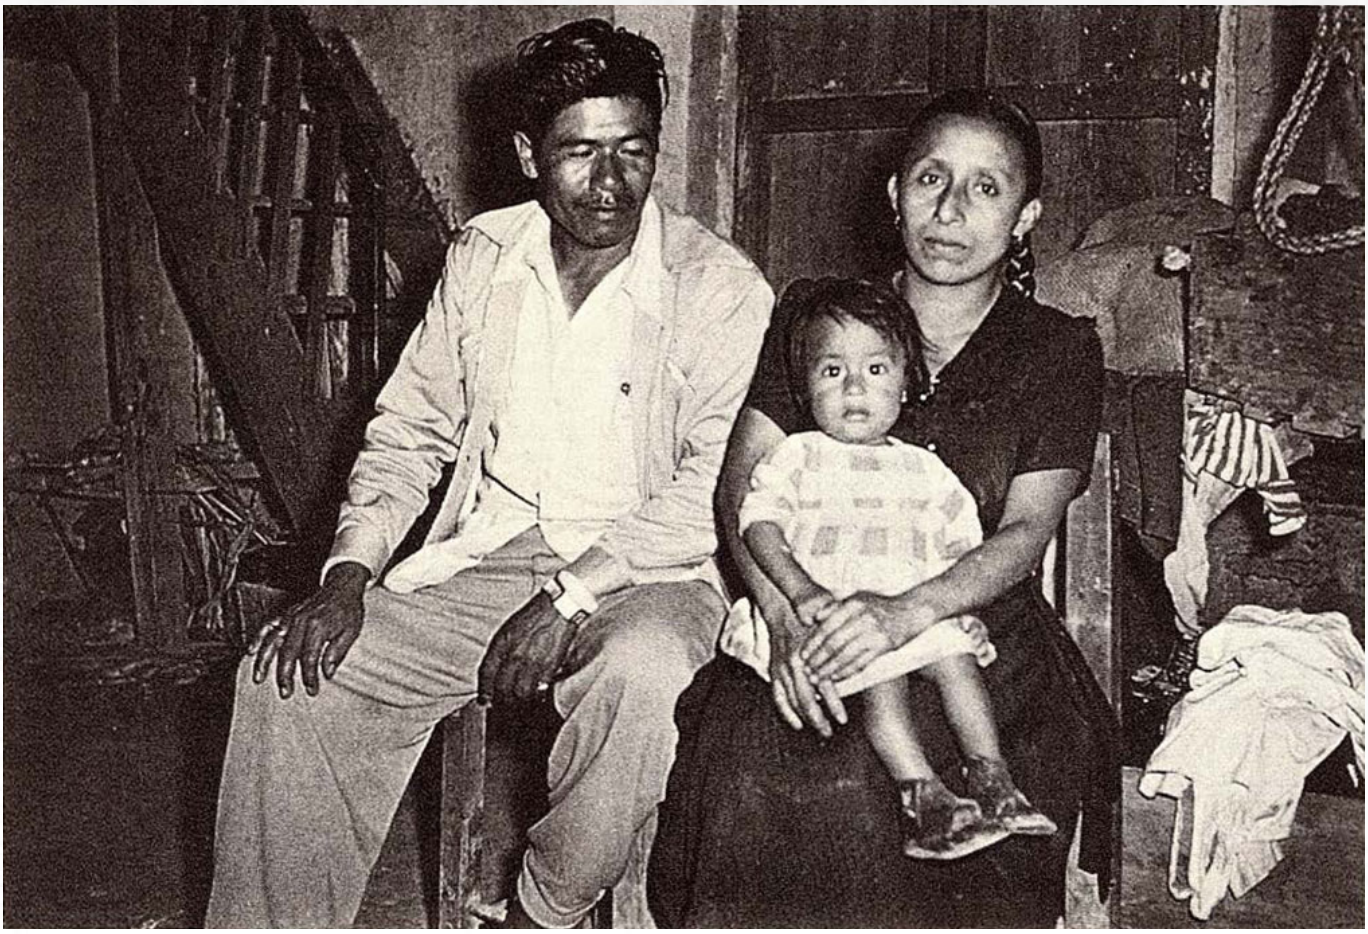

Fig 6 Cayetano García and Guadalupe his wife, with infant

Without leaving his hammock, Cayetano asked his younger brothers Genaro and Emilio to take us down into the gully and show us the mushrooms. And so, a little past 4 o'clock on that Wednesday, down we went perhaps a hundred yards below, to the edge of the stream in the gully. How hot and muggy it was! In the lower reaches of our descent we skirted a field planted to sugar cane, and then arrived at the spot where the cane had been milled, a flat space the size of a threshing floor, thick with rotting bagasse, as the refuse from the mill is called. There in the previous year's bagasse, just as Cayetano had promised, we found an immense crop of mushrooms growing in clusters, of the sacred kind known to our Mazatec friends as *^{ʔ}nti^{1}ki^{3}xo^{3}*, 'landslide', but a mushroom then unknown to me. We photographed them to our hearts' content. We gathered them in a pasteboard box: the sacred mushrooms must always be carried in a closed parcel, never exposed to the view of the passer-by. They were a goodly lot, mostly young, all of them perfect in their moist health and fragrance. With our pasteboard box filled and closed, we carried them up the steep mountainside to the house. We were warned that if we saw arty dead animal on the way, the mushrooms would lose their virtue - happily we saw none. It was in the rainy season, and in the humid heat of that sunny afternoon the climb was long and exhausting.

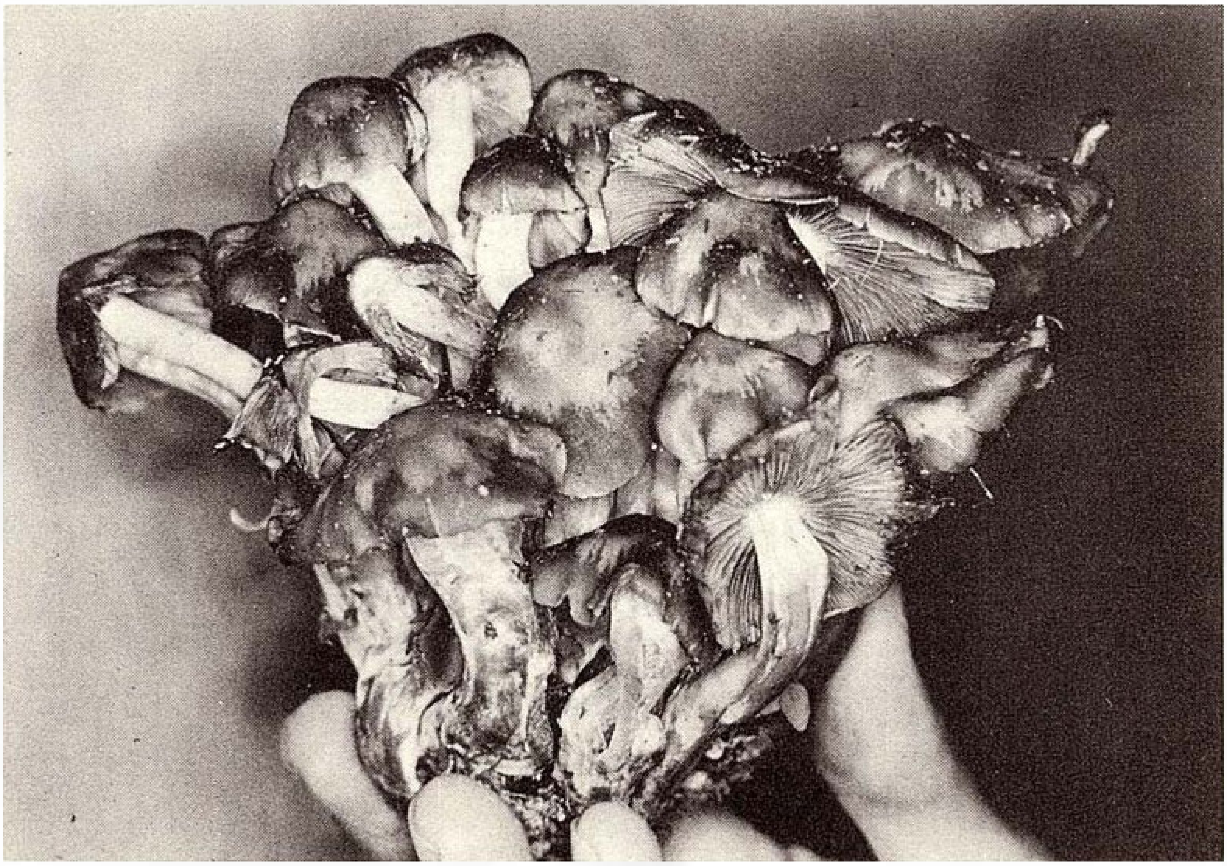

Fig 7 The Sacred Mushroom used in the *velada*, *Psilocybe caerulescens* Murrill var. *mazatecorum* Heim; called in Mazatec 'Landslide Mushroom': *^{ʔ}nti^{1}xi^{3}tho^{3}, ^{ʔ}nti^{1}ki^{3}xo^{3}*

Hardly had we arrived back when Cayetano sent us, with his brother Emilio as interpreter, to a cottage some distance farther up, where he said we would find a *curandera de primera categoría*, a top flight shaman, María Sabina by name. We were to ask her whether she would help us that night. We found the Señora, as our hosts always called her, resting on a *petate*, or mat woven of a palm. She was alone with a daughter who was up and about. After introducing ourselves through Emilio, we showed them our mushrooms, whereupon the two women went into joyful exclamations over their fine condition and beauty. We put our question to the Señora, and without hesitation, looking steadily at us, she said yes, and would we please be in Cayetano's lower room after dark. Neither she nor her daughter spoke a word of Spanish. We do not know whether they had been told to expect our visit. (After writing this I came upon a remarkable interview with María Sabina, written by Alberto Ongaro and published in *L'Europeo* in Milan on 25 November 1971, sixteen years and more after the event, in which she said that the Syndic of Huautla, don Cayetano, had asked her to serve me, why she knew not, and she had felt she had no choice. '*I should have said no.*')

María Sabina was a woman in her fifties, grave in demeanor, with a grave smile, short of stature like all

Mazatecs, dressed in the Mazatec *huipil*. Her daughter was in her thirties and in all respects took after her mother. She was following her mother's vocation. The Señora herself was at the peak of her powers, and it was easy to see why Guadalupe, Cayetano's wife, had said to us of her that she was *una Señora sin mancha*, a lady without blemish, immaculate, one who had never dishonored her calling by using her powers for evil. She alone, said Guadalupe, had brought the latter's children through all the diseases that take a frightful toll in early childhood in the Mazatec country. After that initial talk we were to pass many all-night vigils[5] with María Sabina and her daughter, and we can testify that she was a woman of rare moral and spiritual power, dedicated in her vocation, an artist in her mastery of the techniques of her office. It was her example that drove home for us for the first time a rule that must govern all field anthropologists. In the archaic cultures as among advanced peoples, there is a hierarchy of excellence when it comes to the individuals who are the culture bearers. It is not sufficient to rely on the first informants who present themselves, on any shaman who is willing to talk. The whole cultural area must be discreetly surveyed and communication must be established with the finest exponents of the old traditions. None of the formidable difficulties of physical existence in these remote regions nor of communication should be allowed to blunt this obligation.

On that last Wednesday of June, after nightfall, we gathered in the lower chamber of Cayetano's house. This lower story is built on one side against the mountain face, and on the other side by a door it leads to a terrace perhaps six feet wide, which then falls sharply away into the ravine about 300 feet below. Across the valley and beyond, the Sierra Mazateca in all its verdant glory fills the distant view. On the terrace at one end of the house a flimsy wooden thatched annex had been constructed to serve as a kitchen. The interior was divided by a whitewashed adobe wall into two rooms. (Chart p. 6, Fig. 5) There is no window in either room, but over the door on the terrace a transom admits some light. This room was well sheltered from the life of the village and doubly so after dark when the villagers refrain from stirring abroad. The family circle was large: our hosts' small children were numerous and Cayetano's brothers and parents were also much in evidence. Chickens and turkeys had the run of the lower floor. A black hen sitting on her eggs on one of the cluttered tables was a silent witness to what went on. In all, at one time or another, there must have been a dozen persons present, mostly members old and young of Cayetano's family. The Señora came with her daughter Apolonia. They and all the others were pleased when we photographed them, and we took numerous pictures throughout the preliminaries, except for Cayetano's father and mother, who steadfastly refused. But the Señora requested through Cayetano that when the power would seize her - *cuando la fuerza le agarrara* - we should desist, and of course we did so. Cayetano had his ten-year-old daughter serve us chocolate to drink, graciously but somewhat ceremonially. (We learned later that the daughter must be a virgin, *una doncella*.) At once my thoughts flashed back to Bernardino de Sahagún in the sixteenth century, who quoted his informants as saying that chocolate was served before the mushrooms were taken. I turned to my companion: 'Allan', I said, 'this is it. We are in for it, for better or for worse!' Cayetano also offered us coffee and sweet wheaten bread, neither of which had been known to his ancestors in pre-Conquest Mexico, which we declined. Both Allan Richardson and I were deeply impressed by the mood of the gathering. We were received and the night's events unrolled in an atmosphere of simple friendliness that reminded us of the agapé of early Christian times. There was no familiarity. The mushrooms were treated respectfully, as sacred, but without marked formality. The proceedings went forward with an easy decorum. Neither on this occasion nor at any other time or place have we ever seen or heard the mushrooms treated as a subject for jocular vulgarity, of the kind that often marks the use of alcohol among 'civilized' peoples. The atmosphere of respectful friendliness was infectious, and we enjoyed reciprocating the welcome extended to us. There is no record that any white men had ever attended a session of the kind that we are going to describe, nor that white men had ever partaken of the sacred mushrooms under any circumstances. For reasons deeply rooted in the mortal cultural conflict of Spaniards and Indians, it is unlikely that any unrecorded event of the kind had ever taken place. By hearsay Sahagún, Ruiz de Alarcon, and other early Spanish writers had reported gatherings of Indians where the hallucinogen was served to many, but we had thought from our previous visits to Mexico that such observances were today unknown. We were now to learn that they still go on, and that they are even today a central experience in the culture of the Mazatec people. The gatherings now are held behind closed doors, but as the 'consultation' with the Sacred Mushroom is a private, domestic matter, must not such gatherings always have been private?

---

[5] We picked up from Spanish-speaking Mazatecs of Huautla the word *velada* as the designation of the all-night vigil of the shaman. Only years later did we learn from Alvaro Estrada, a Mazatec, that María Sabina used the Mazatec equivalent, *je^{2}xi^{3}vi^{3}jna^{3}choan^{3}-ve^{4}*, meaning 'what keeps us awake', *eso que nos desvela*.

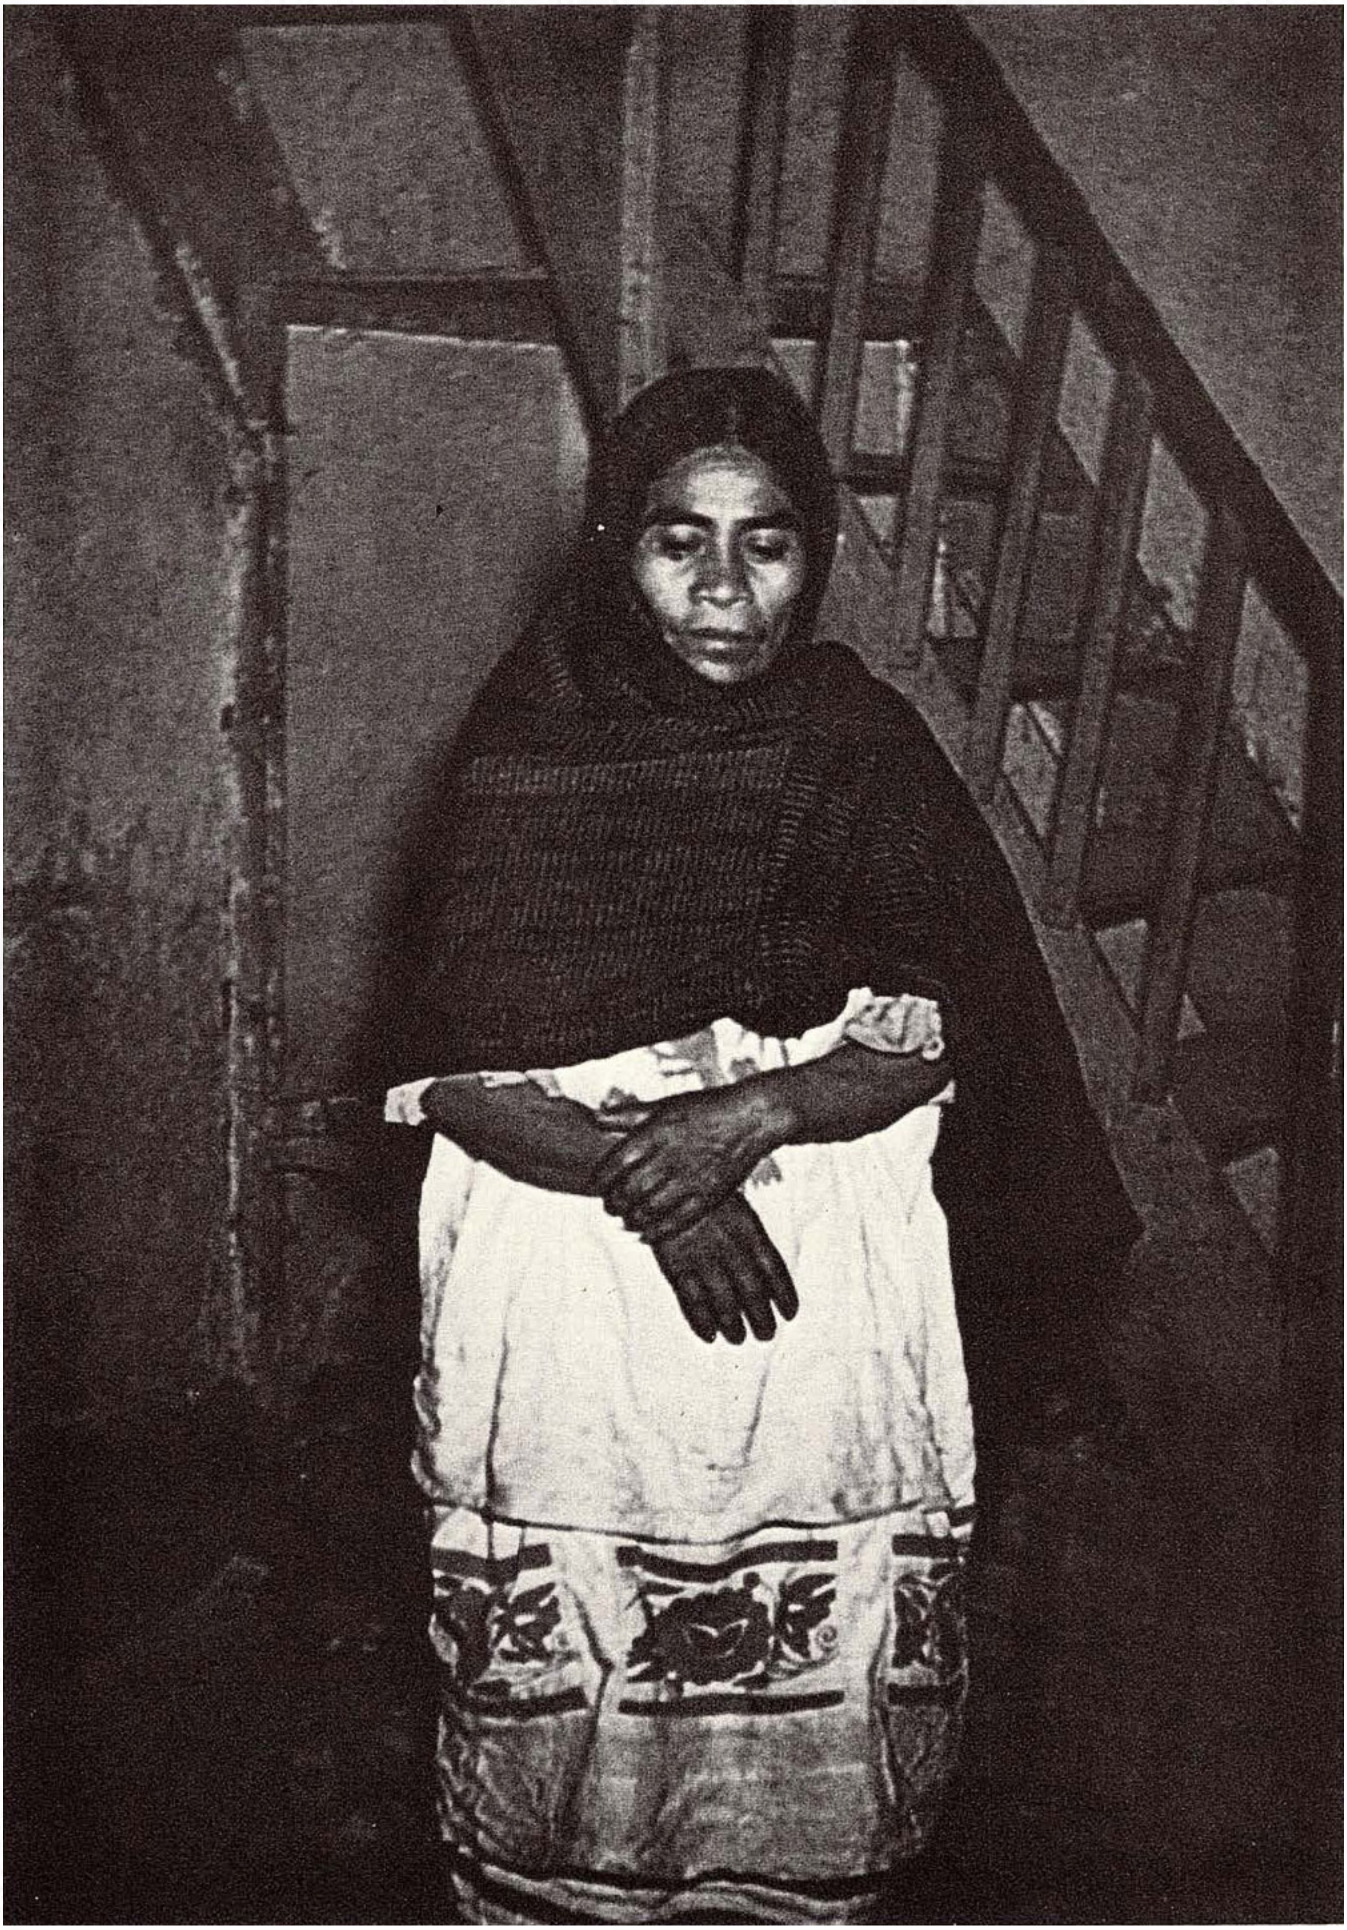

Fig 8 María Sabina

Cayetano told us early in the evening that no one on any account should leave the house before break of day, and for the necessities of nature he showed us the rudimentary provision that had been made in one corner of the other room. The contempt of the Spaniards for indigenous rites and the Church's condemnation of them as idolatrous heresies have not killed these assemblies of ancient lineage but have certainly driven them under deeper cover. Our hosts were obviously pleased by our intense and sympathetic interest in all that went on before our eyes. The very fact of our participation must have made the evening memorable for them. They were dressed up for the occasion. Genaro in particular was resplendent in his handsome striped *sarape* and his freshly washed white cotton trousers or bags, *bombachas*, which Indian-style were buttonless, being supported by strings tied around the waist. By our respectful behavior we did all we could to make clear that for us the rite we were witnessing possessed full religious stature. We were mindful of the drama of our situation. We were attending as participants a mushroomic Supper of unique anthropological interest, which was being held pursuant to a tradition of unfathomed age.

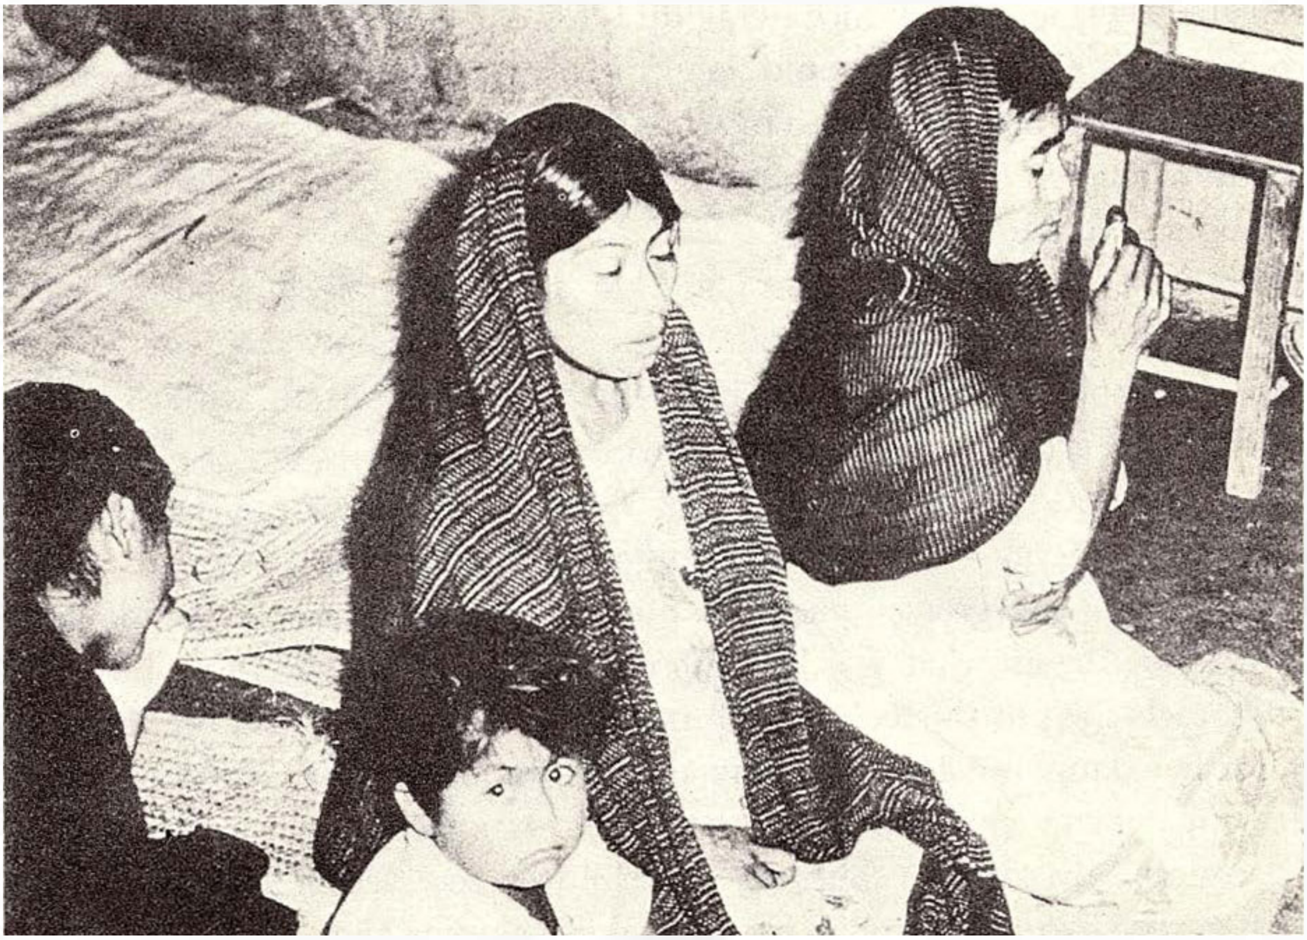

Fig 9 Adoration of the Mushroom. María Sabina, *sabia*, and her daughter Apolonia. Huautla de Jiménez, June 29-30, 1955

There were a few home-made wooden chairs in the room, and in the beginning Allan and I used them, my chair in the corner of the room to the left of the altar table. Cayetano's brother Genaro and possibly one other remained seated on chairs the whole night through. The others lay or reclined on mats on the floor, wrapped in *sarapes*, except of course for the Señora and her daughter, who, wearing clean *huipiles* with identical red birds embroidered on them, sat before the altar table on mats. They sat with what seemed a half-studied formality, the daughter a little behind her mother and slightly to her mother's right. Later, in the dark, we could barely discern their triangular shadows as first one and then the other lifted her voice in song. It was then, when the details were erased by darkness and only the geometric mass persisted, that they forcibly reminded me of the pyramids that are the outstanding feature of architecture in pre-Conquest Mexico. Might not the pyramids have been originally a geometric stylization of the worshipping Indian seated on his mat, of the gods that were his magnified projection of himself?

Before we go further we must mention that when we had bespoken the Señora's services in the afternoon, she had asked us what problem was troubling us. Prepared for this, I asked about our son Peter, then in the army.

How was he? Alive or dead, or ill, or in good spirits, or in some trouble? This had seemed to her a sufficient justification. We had counted on Cayetano to stay with us through the night as our guide and interpreter. We observed that neither he nor Guadalupe were taking the mushrooms. As we were finishing ours, Cayetano informed us that he and his wife were withdrawing up the stairs and through the trap-door to the room above, where they would guard us against interruptions from the street. He was leaving his brother Emilio to act as our mentor. We sensed that each of the other adults who were taking the mushrooms was consulting María Sabina, as we were, about individual problems.

At about 10: 30 o'clock the Señora and her daughter took their positions before the small table that served for an altar. On it were two holy pictures, on the left the Holy Child of Atocha and on the right the Baptism in Jordan, with a bouquet in front of them, a crucifix hidden in the flowers, three lighted candles of virgin beeswax, and a lighted wick in a glass of wax. There were also two pottery bowls and some cups. The Señora then went through our box of mushrooms, brushing off with her fingers the grosser pieces of dirt and passing them in her hand over *copal* (incense of resin) that was burning on a metal lid on the floor. Into each of the two bowls she put thirteen pair of mushrooms; one bowl was for her and the other for her daughter. Into each cup she put four pair, or five, or six, and then handed the cups to the grown-ups who were to take them. (The mushrooms are always counted by pairs, in couples.) The children received none. They were profoundly moved by the singing and events taking place in their presence. To me she handed a cup with six pair. Our readers will imagine my joy at this dramatic culmination to years of pursuit. Then she handed a cup with six pair to poor Allan. Mary, his wife, had reluctantly consented to his coming with me only on his solemn promise not to let those nasty toadstools cross his lips. He faced a behavior dilemma, but to have refused might have disappointed our friendly Indian companions, and so he coped with the immediate problem first and took the cup. (Later, with him safely back in New York, Mary gave him ready absolution.) By now all lights in the room were out except the wick in the glass. Following the Señora's example, we began to chew and swallow our mushrooms.

Our *curandera* ate cap and stem and we did likewise. She ate them one by one, with utmost gravity, chewing each one for a long time. She did not pick them up by pairs, as Aurelio Carreras had done in 1953. She picked them up one by one, although in apportioning them she had counted them by pairs. The flavor of the mushrooms is acrid and unpleasant. The distinctive flavor would repeat itself, as a gaseous beverage does, and pervade the nasal passage. I have since discovered that the Indians, by contrast with us, find the taste delectable. (Long afterwards Robert Weitlaner likened the taste to rancid grease, a taste unfamiliar to us. At the time this narrative is being written, in 1977, I have eaten many species of the divinatory mushrooms used in Mesoamerica, and they are all marked by this singular and unforgettable taste and aftertaste, which seem to be the veritable signature of the divine species.)

We all ate our mushrooms facing the wall where the small altar table stood. We ate them in silence, except for Cayetano's father, don Emilio, who was consulting the mushrooms about his infected left forearm. He would jerk his head violently with each mushroom that he swallowed, and utter a smacking noise, as though in acknowledgement of their divine potency. As I said before, I had been seated in the corner of the room on the left of the altar, a vantage point from which I could observe everything that was happening. Through Cayetano, the Señora asked me to move because the Word would come down there.

Twenty years later, in telling the story of her life to Alvaro Estrada, the Señora explained her conception of 'the Word': in a notable passage she says:

> ... veo que el Lenguaje cae, viene de arriba, como si fuesen pequenos objetos luminosos que caen del cielo. El Lenguaje cae sobre la mesa sagrada, cae sobre mi cuerpo. Entonces atrapo con mis manos palabra por palabra.
> [*La Vida de María Sabina*, p 58, 126]
>
> ... I see the Word fall, come down from above, as though they were little luminous objects falling from heaven. The Word falls on the Holy Table, on my body: with my hand I catch them, Word by Word.

The Señora conceives a mystical opening ('*boquete*') in the roof or high up in the wall. In her mind she adds another dimension to the matters that we discuss further in Chapter 7.

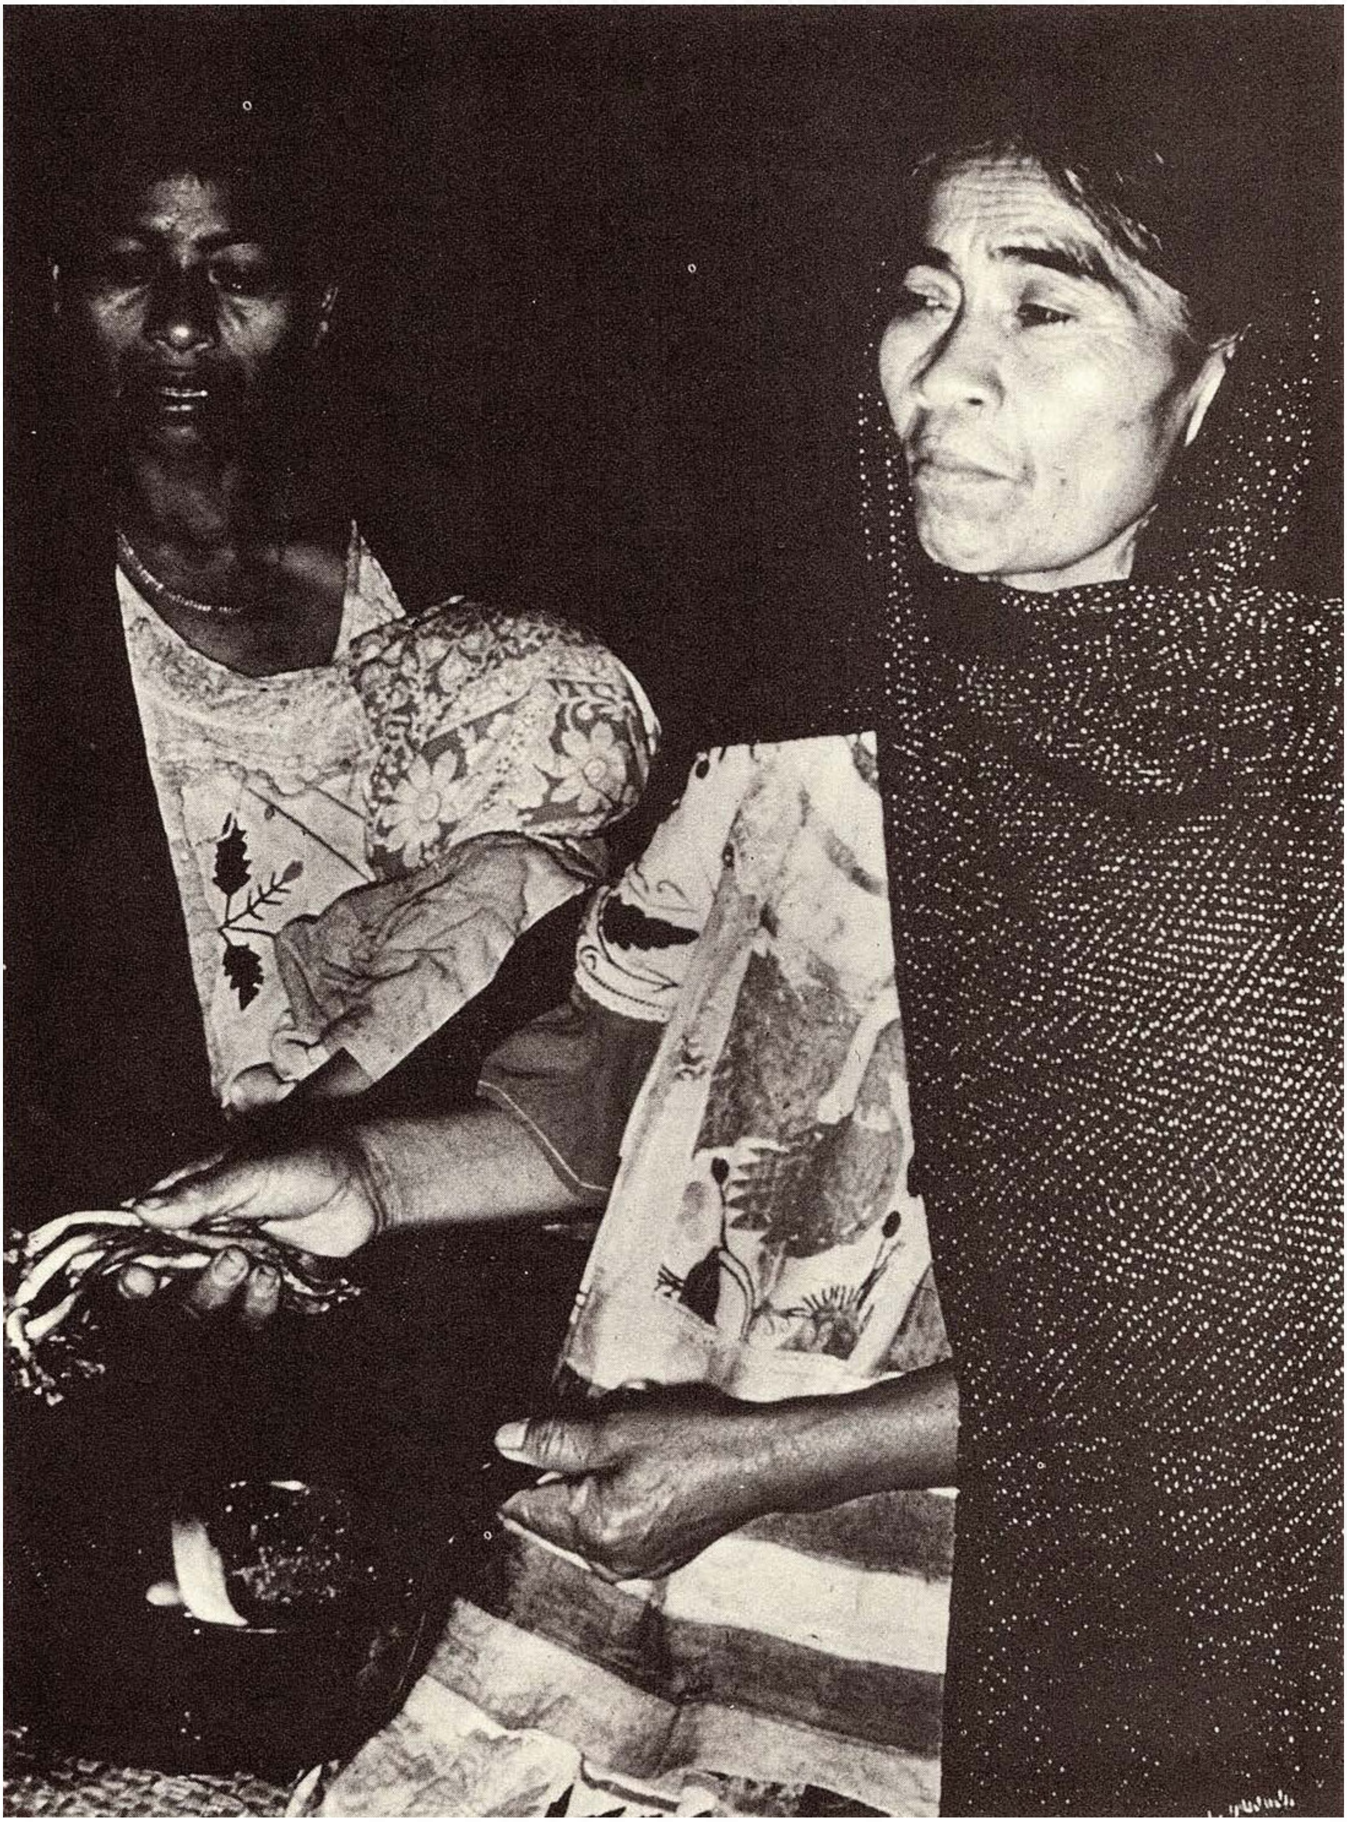

Fig 10 María Sabina incensing the mushroom, 12-13 July 1958, with Apolonia

I joined Allan on my chair immediately behind the Señora. We took about a half hour to eat our six pair of mushrooms. By eleven o'clock we had all finished our respective portions, the Señora crossing herself with the last swallow. Then we waited in silence. After about twenty minutes the Señora plucked a flower from the bouquet and with it inverted as an extinguisher put out the last of the *velas*. We should have been in stygian darkness, but by good fortune the night was clear and a gibbous moon, by the transom above the door, gave us just enough light to make our darkness visible.

At about 11:20 o'clock Allan leaned from his chair and whispered to me that he was having a chill. We wrapped him in a blanket. A little later he leaned over again and said, 'Gordon, I am beginning to see things', to which I gave him the comforting reply that I was too. Allan lay down along the wall on the large *petate* that had been spread for us, and shortly afterwards I joined him.

Except for the children who had eaten no mushrooms, no one slept that night until about 4 o'clock in the morning. (The last entry in my notebook carries the hour 3:50.) There was no inclination to sleep. At all times we were alert both to our subjective experiences and to the goings-on around us in the dark. I took imperfect notes intermittently and kept track of the hours. But Allan and I were both alive to the fact that we were not ourselves. I was of two minds about the mushrooms. On the one hand I wished to experience them to the full, to know what the Indians were experiencing, and on the other hand I wished to fight off any effects and remain the detached observer. But the mushrooms gave me no choice. They took full and sweeping possession of me. There is no better way to describe the sensation than to say that it was as though my very soul had been scooped out of my body and translated to a point floating in space, leaving behind the husk of clay, my body. Our bodies lay there while our souls soared. We both felt nauseated; twice I made my way to the other room to vomit, Allan three times. One or two others, not identified in the darkness, did likewise. (I remember how disappointed I was at throwing up: I feared I would not feel the full effect!) But these episodes seemed of no moment. For we were both seeing visions, similar but not identical visions, and we were comparing notes in whispered interchanges. At first we saw geometric patterns, angular not circular, in richest colors, such as might adorn textiles or carpets. Then the patterns grew into architectural structures, with colonnades and architraves, patios of regal splendor, the stone-work all in brilliant colors, gold and onyx and ebony, all most harmoniously and ingeniously contrived, in richest magnificence extending beyond the reach of sight. For some reason these architectural visions seemed oriental, though at every stage I pointed out to myself that they could not be identified with any specific oriental country. They were neither Japanese nor Chinese nor Indian nor Moslem. They seemed to belong rather to the imaginary architecture described by the visionaries of the Bible. In the aesthetics of this discovered world Attic simplicity had no place: everything was resplendently rich.

At one point in the faint moonlight the bouquet on the table assumed the dimensions and shape of an imperial conveyance, a triumphal car, drawn by zoological creatures conceivable only in an imaginary mythology, bearing a woman clothed in regal splendor. With our eyes wide open, the visions came in endless succession, each growing out of the preceding one. We had the sensation that the walls of our humble house had vanished, that our untrammeled souls were floating in the empyrean, stroked by divine breezes, possessed of a divine mobility that would transport us anywhere on the wings of a thought. Now it was clear why don Aurelio in 1953 and others too had told us that the mushrooms *le llevan ahí donde Dios está* - would take you there where God is. Only when by an act of conscious effort I touched the wall of Cayetano's house would I be brought back to the confines of the room where we all were, and this touch with reality seemed to be what precipitated nausea in me.

On that night of 29-30 June we saw no human beings in our visions. (The woman in regal attire was certainly not human.) On the night of 2-3 July I again took mushrooms in the same room, with the Señora again serving as votary. If we may anticipate our story, on that second occasion my visions were different. There were no geometrical patterns, no edifices of oriental splendor. The patterns were replaced by artistic motifs of the Elizabethan and Jacobean periods in England - armor worn for fashionable display, family escutcheons, the carvings of choir stalls and cathedral chairs. No patina of age hung on them. They were all fresh from God's workshop, pristine in their finish. The beholder could only sigh after the skill that might have fixed those beauteous shapes on paper or in metal or wood, that they might not be lost in a vision. They too grew one out of the other, the new one emerging from the center of its predecessor. Here as in the first night the visions seemed freighted with significance. They seemed the very archetypes of beautiful form and color. We felt ourselves in the presence of the Ideas that Plato had talked about. In saying this let not the reader think that we are indulging in rhetoric, straining to command his attention by an extravagant figure of speech. For the world our visions were and must remain 'hallucinations'. But for us at that moment they were not false or shadowy suggestions of real things, figments of an unhinged imagination. What we were seeing was, we knew, the only reality, of which the counterparts of every day are mere imperfect adumbrations. At the time we ourselves were alive to the novelty of this our discovery, and astonished by it. Whatever their provenience, the blunt and startling fact is that our visions were sensed more clearly, were superior in all their attributes, were more authoritative, for us who were experiencing them, than what passes for mundane reality.

Following the visions that we have already described, on both occasions I saw landscapes. On Wednesday they were of a vast desert seen from afar, with lofty mountains beyond, terrace above terrace. Camel caravans were making their way across the mountain slopes. On Saturday the landscapes were of the estuaries of immense rivers brimming over with pellucid water, broad sheets of water overflowing into the reeds that stretched equally far from the shore line. Here the colors were in pastel shades. The light was good but soft as from a horizontal sun. On both nights the landscapes responded to the command of the beholder: when a detail interested him, the landscape approached with the speed of light and the detail was made manifest. When I was seeing the camel caravans in the distance, an impulse seized me: right away I was upon them, listening to the sounds of their heavy breathing, to the camel bells, to their lurching with their loads, smelling their stench. On Saturday there seemed to be no birds and no human life in the river estuary, until a rude cabin suddenly appeared with a motionless woman nearby, seated on a block of stone. She was a woman by her figure and face and costume, and of course the vision was in color. I could see her breathing. But she was a statue in that she sat there without expression, doing nothing, staring into the distance. She might be compared to those archaic Greek sculptures where the woman gazes into space, or, better yet, the departing woman on the Greek funerary stele who looks into eternity, except that our vision was of a living woman whereas the Greek sculptures, marble white, are mere imitations in stone of what we were seeing. Elsewhere I once wrote that the bemushroomed person is poised in space, a disembodied eye, invisible, incorporeal, seeing not seen. In truth he is the five senses disembodied, all of them keyed to the height of sensitivity and awareness, all of them blending into one another most strangely, until the person, utterly passive, becomes a pure receptor, infinitely delicate, of sensations. What you are seeing and what you are hearing appear as one: singing and percussive beat assume harmonious shapes, giving visual form to their harmonies, and what you are seeing takes on the modalities of music - the music of the spheres. Likewise with your sense of touch, of taste, of odor: all your senses seem to function as one. My olfactory sense has always been weak, but now for the first time I entered into the world of odors, delicate iridescent harmonies in which other creatures spend their lives.

On both nights I stood up for a long time in Cayetano's room, at the foot of the stairway, holding on to the rail, transfixed in ecstasy by the visions that I was seeing in the darkness with open eyes. For the first time that word 'ecstasy' took on subjective meaning for me. 'Ecstasy' was not someone else's state of mind. It was no longer a trite superlative cheapened by overuse and abuse. It signified something different and superior in kind, about which I could now testify as a competent witness. There came one moment on Saturday when it seemed as though the visions themselves were about to be transcended, and dark gates reaching upward beyond sight were about to part, and I was to find myself in the presence of the Ultimate. I seemed to be flying toward those august gates as a swallow at a dazzling lighthouse, and the gates were to part and admit me. But they did not open, and with a thud I fell back breathless and gasping. I felt disappointed, but also frightened and half relieved, that I had not entered into the presence of the Ineffable, whence, it seemed to me at the time, I might not have returned, for I had sensed that a willing extinction in the divine radiance had been awaiting me.

(Later in the Zapotec country, the shaman Aristeo Matías told us in a stirring parable the four stages that one must go through from the initial surprise and mental disorder until one finally arrives at the mastery of the mushroom. Here was fatherly advice from an old hand to us who had told him that we aspired to enter upon his vocation. He was telling us that there is or at least can be a growth, an evolution, in the entheogenic experiences induced by the mushrooms. After many experiences with the mushrooms I do not doubt what don Aristeo said. At first the beginner is confused and lost in wonder, but with repeated experience he comes to deal with the mushrooms on equal terms. His initial disorientation contrasts sharply with the discipline that the shaman shows, who has taken an immense dose and whose performance is timed to a nicety, even syncopated.)

Throughout that night in June we were split in the very core of our being. On one level, space was annihilated for us and we were traveling as fast as thought to our visionary worlds. On another level we were lying there on our *petates*, trying to take notes, Allan and I exchanging whispered comments, alive to every twitch and twinge in our heavy (oh so heavy!) earth-bound bodies of clay. At the same time we were both held in thrall by what was going on in the room around us. For the Señora and her daughter were engaged all night in a religious performance that we had not expected and that no one had ever described to us.

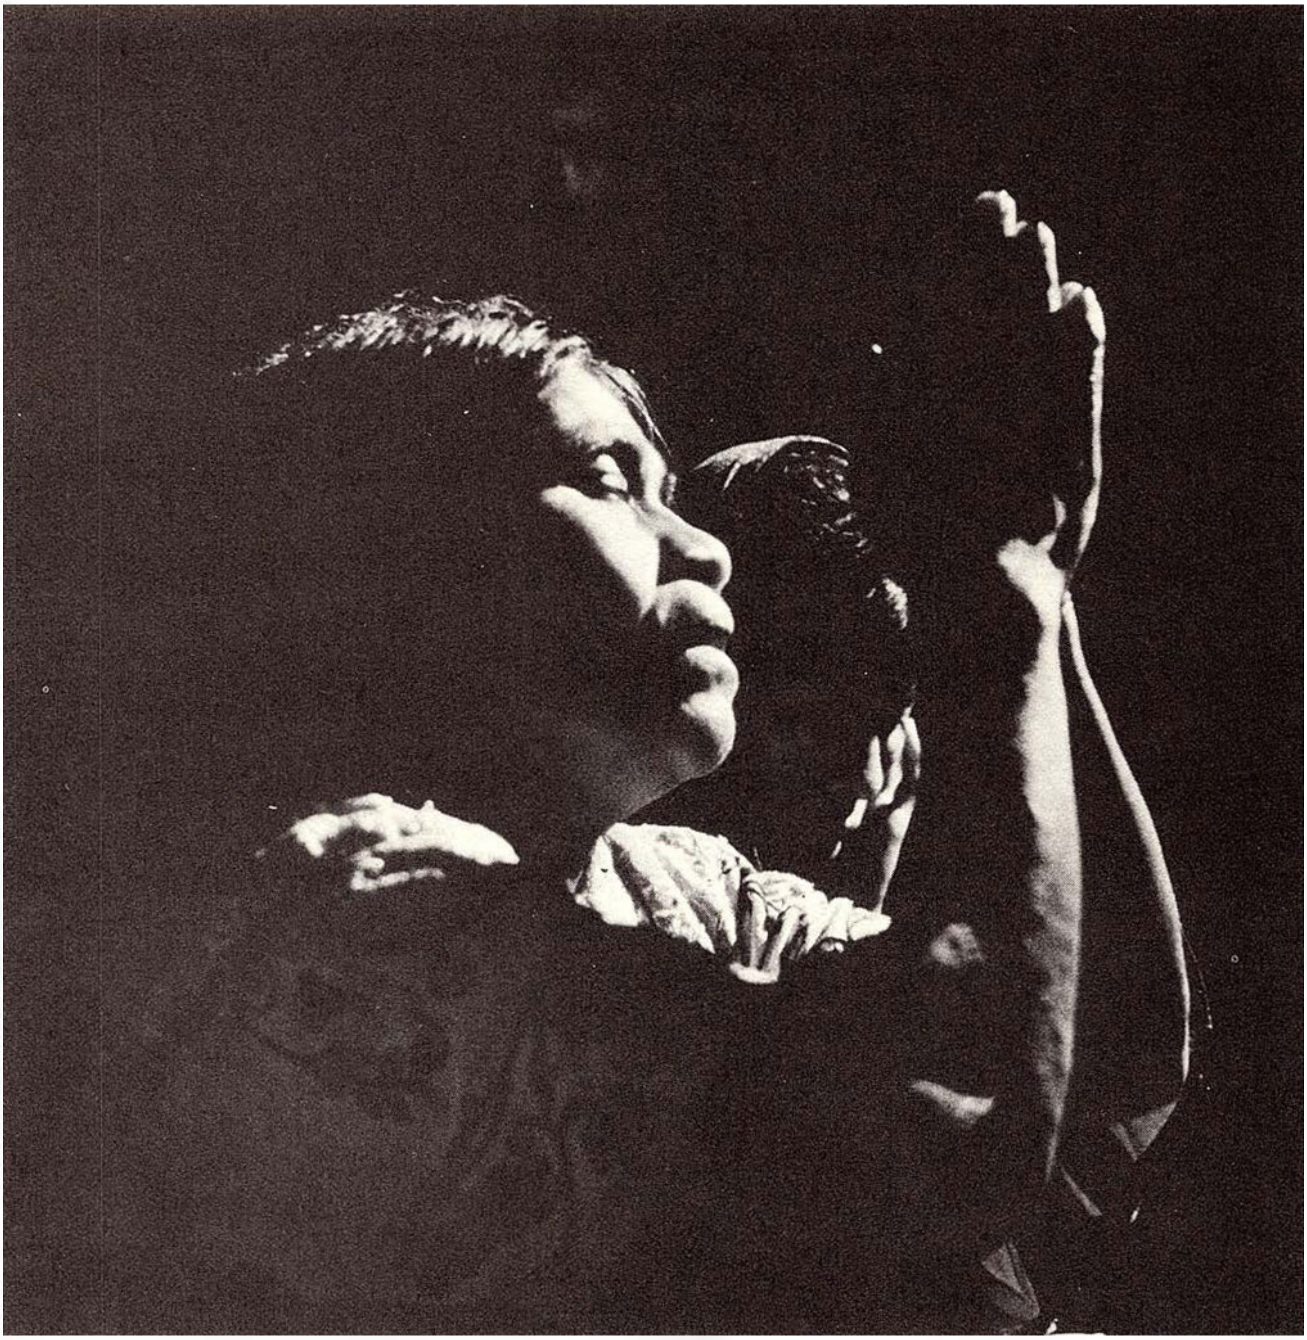

Figure 11 María Sabina invoking the Sacred Mushrooms

After the Señora had put out the last *vela*, a silence of perhaps twenty minutes followed. The moon was shining brightly outside, and its orbit was such that the shaft of moonlight entering above the door fell squarely on the altar table, but it did little to relieve the general darkness in the room. Suddenly the Señora began to moan, low at first, then louder. There were silent pauses, and then renewed humming. Then the humming stopped and she began to articulate isolated syllables, each syllable consisting of a consonant followed by a vowel, sharply pronounced. The syllables came snapping out in rapid succession, cutting the darkness like a knife, spoken, not sung. After a time the syllables coalesced into what we took for words, and the Señora began to chant. The chanting continued intermittently all night, first by the Señora and then by her daughter, and afterwards alternately by one or the other. The chanting was in Mazatec, only occasionally in Latin or Spanish learned by rote, and there was no one to translate the words for us. I have since learned that most of the music was native in provenience. Both women chanted in that distinctive way which seems always to mark the intoning of age-old chants; much of the singing seemed to me soaked in weary melancholy. Our Señora's voice was not loud, probably not loud enough to be heard in the village thoroughfare. But there was a confidence and resonance in her utterance that imposed itself. There came a moment late in the night when the Señora made her way to the door on the terrace and went outside, holding her hand on the door. (She was free of the prohibition laid on the rest of us not to leave the house.) When she re-entered, she left the door slightly ajar, and we saw her advance on her knees across the open space in the room, and then turn to the right toward the altar table. Her hands were uplifted to shoulder level, palms exposed. As she slowly progressed, she sang a canticle that seemed like an introit, indescribably tender and plaintive in its musical phrases. Her daughter sang well too, but lacked her authority. From time to time, as they sang, the men who had taken the mushrooms, notably Genaro and young Emilio, ejaculated words, groans, short sentences, and vocal noises. We know not what they said, but they seemed to intervene with their voices to suit the singing, in such a way as to produce a strange harmony.

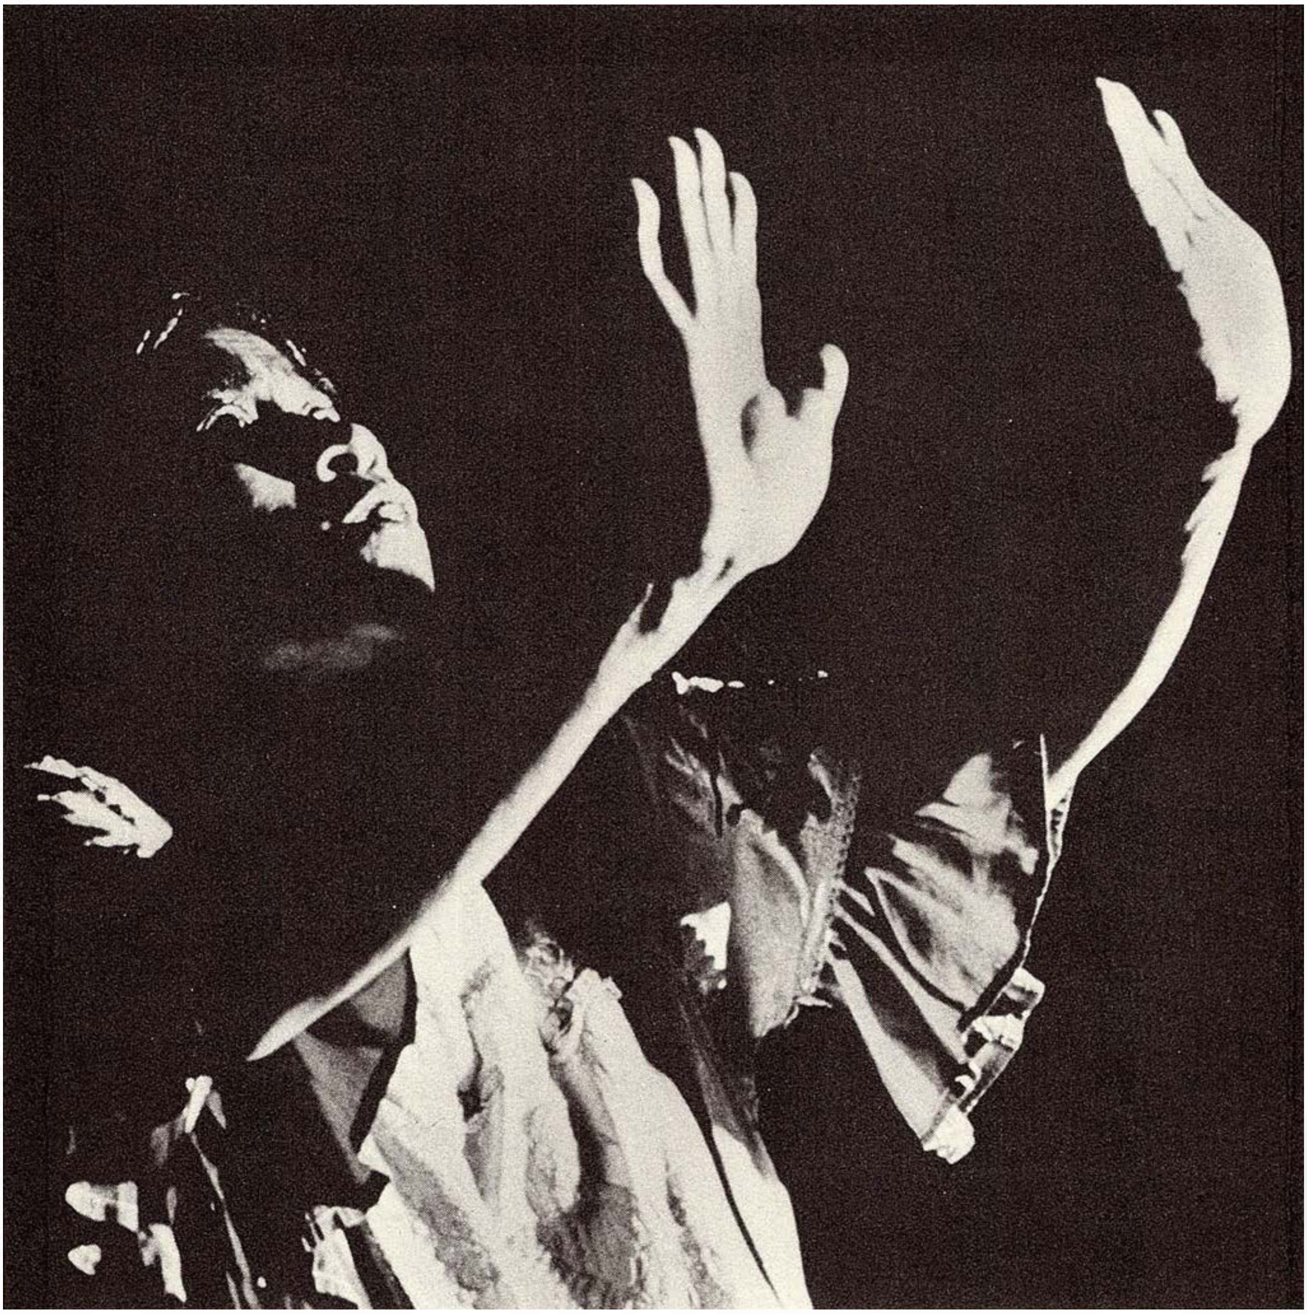

Figure 12

The singing was not continuous. For stretches the Señora would talk, as though invoking the Spirits or as though the Holy Ghost was speaking through the mushrooms. We heard the names of Christ (which she pronounced with an intrusive 'r', *Khristros*), of St Peter and St Paul. We heard her cry out 'Pedro' repeatedly in an imploring tone, and knew that the mushrooms were wrestling with the problem of Peter. Emilio made his way to us and whispered that Peter was alive and well, and contrite for not having let us hear from him. We asked for further details, but Emilio said that since we ourselves had eaten the mushrooms, we could expect them to speak to us directly. Our interpreter Emilio then vanished into the darkness for the rest of the night.

Unlike the chants, the spoken utterances were fresh and vibrant and rich in expressiveness. The mushrooms were talking to the point. We had never suspected how sensitive and poetic an instrument the Mazatec language could be. The intermittent snatches of the Señora's monologue seemed quick with subtle feeling, laden with dramatic import. In our very presence a priestess of the old religion was pronouncing oracular dictates in spurts, hot and firm with authority. How we regretted that we had no means to record her voice![6] (At the time we asked ourselves whether our critical faculties were deranged by the effects of the mushrooms, so that we overrated the quality of the Señora's performance. Later when we taped the singing, we found this was certainly so. But here is an aberration typical of the syndrome of mushroomic ecstasy, and our account at least serves to document it for the record, and to establish that our hallucinations were of all the senses, not merely visual.)

The chanting and the oracular utterances turned out to be only a part of what we were to witness. At an early stage we sensed that the Señora was either kneeling or standing before the altar table gesticulating with her arms. We detected this by ear and confirmed it uncertainly with the aid of the meagre moonlight. Then, much later in the night when her daughter took over the chanting, the Señora made her way to the open space between us and the door, and she embarked on a kind of dance that must have lasted for two hours or more. This is the only occasion when I have seen her dancing: in retrospect, clearly she was putting on for us a very special performance. We do not know precisely what she did, because of the darkness, but she was between us and the aperture above the door, and we could just make our that she was turning clock-wise, facing in succession each of the four compass points, at the same time raising and lowering her arms. Her daughter was singing, but she was not silent. She was engaged in a lengthy rhythmic percussive utterance of a kind unfamiliar to us. There was a differentiation in the pitch of the beats and at times the pattern or phrases seemed to us complex. We cannot say for sure how she made her sounds, but we surmised that she clapped her hands, slapped her knees, smacked her forehead, and whammed her chest. We were impressed by the cleanness of the utterance. Every clap or slap or smack or wham was resonant. The percussive effect varied sharply in timing and in volume, and was frequently syncopated. Remembering the rôle played by pitch in the Mazatec language, we asked ourselves whether the Señora was speaking percussively. On each of our two nights with her, she rinsed her mouth once with water, and the gargling was also rhythmic, and perhaps tonally differentiated. Then she would spit out the water on the ground unrhythmically. On Saturday night, in a moment of illumination by flashlight, we saw and heard her twicking her long finger nails rhythmically. A remarkable feature of her percussive utterance on Wednesday night was its ventriloquistic property. For a long stretch we were in the blackest darkness while the daughter sang and the Señora was performing her strange dance with percussive accompaniment. As she would snap out her resonant claps and smacks, we seemed to catch them out of the night from various directions. Let the reader remember that all the while we were seeing our visions *and* attending to the auditory sensations served to us by these two women. There we were, visually suspended in space before the vast panorama of, say, the Gobi Desert, with a singing accompaniment and with percussive cracks assailing us, now from above, now here, now there, exactly like Hamlet's ghost *hic et ubique*, hitting us with a cutting crispness from unpredictable quarters, from underneath us in a whisper, beyond our feet on the *petate*, out of the night, as though an air borne choir of invisible creatures was peopling the dark void around us, perplexing us with their assorted and shifting cries. Possibly this ventriloquistic effect was caused by the Señora's turning in different directions as she performed, so that the sound caromed to us from the ceiling or walls.[7] And all the while there was the irregular chorus, subdued in volume, of ecstatic exclamations from the Indians reclining on the ground. Confined though we were in a room without windows or open door, at one point we felt a swish of air, just as though we were really suspended in the great outdoors. Was this too an hallucination? If so, all shared it, for when the wind blew on us, there was general excitement, flashlights were switched on, and our Indian friends were sitting up, amazed at being stroked by the Divine Afflatus.

---

6. We published a partial recording of a *velada* held in 1956, Folkways Record and Service Corporation FR 8975. The translation and commentary were done by Eunice V. Pike and Sarah C. Gudschinsky. This was followed by a full-dress edition of a complete *velada* that took place in 1958: *María Sabina and her Mazatec Mushroom Velada*, Harcourt Brace Jovanovich, Inc., New York, 1974. George and Florence Cowan served as our linguists, Willard Rhodes as our ethno-musicologist. The translation of the 1956 *velada* was done afresh, into Spanish, by Alvaro Estrada with the cooperation of María Sabina and certain senior Huautecos, and published in 1977 in *La Vida de María Sabina*, pp 133-160.
7. Written in 1956 or 1957. But see pp 34-35 for the explanation of the ventriloquism.

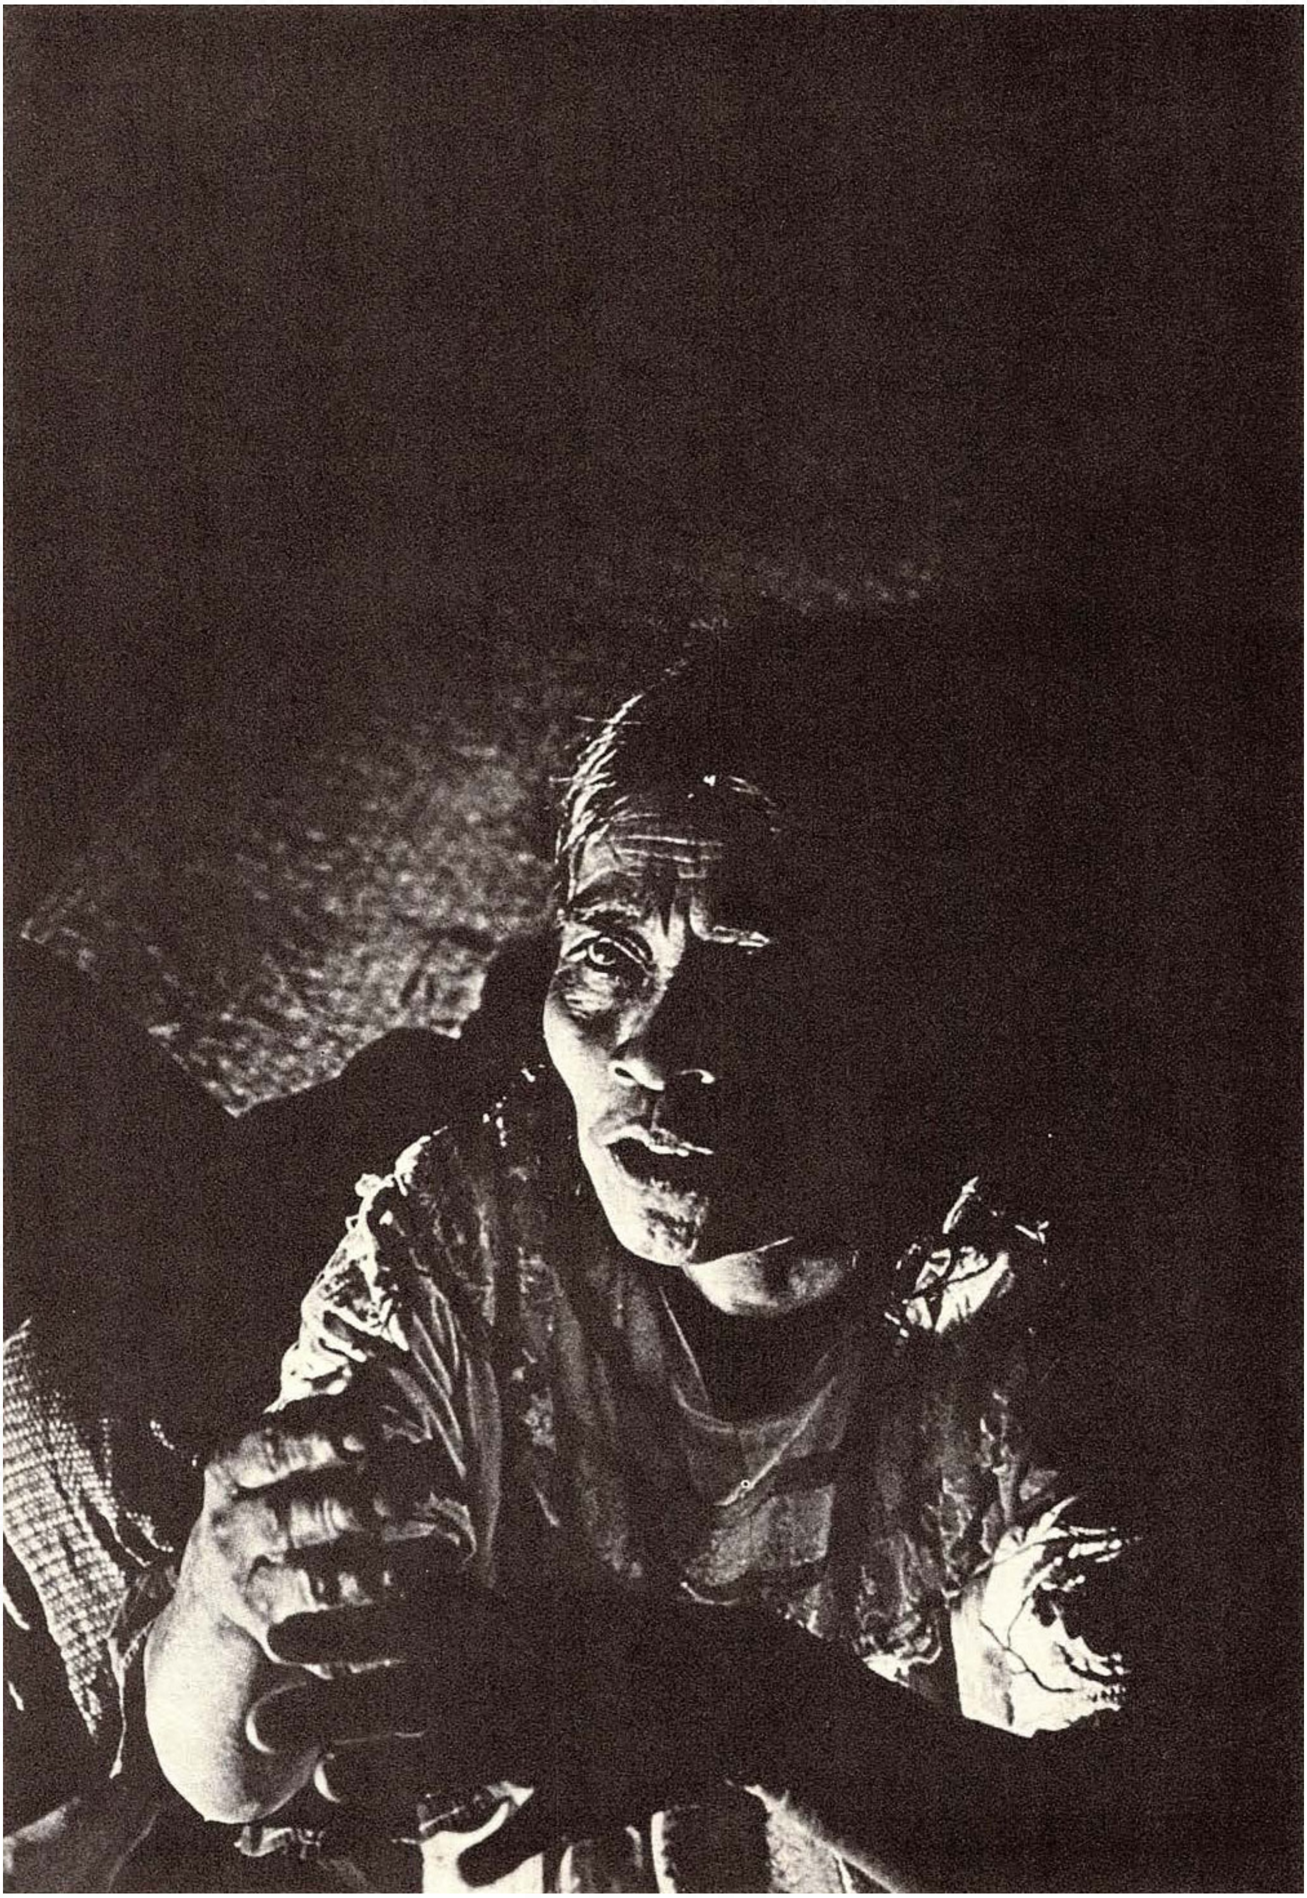

Figure 13

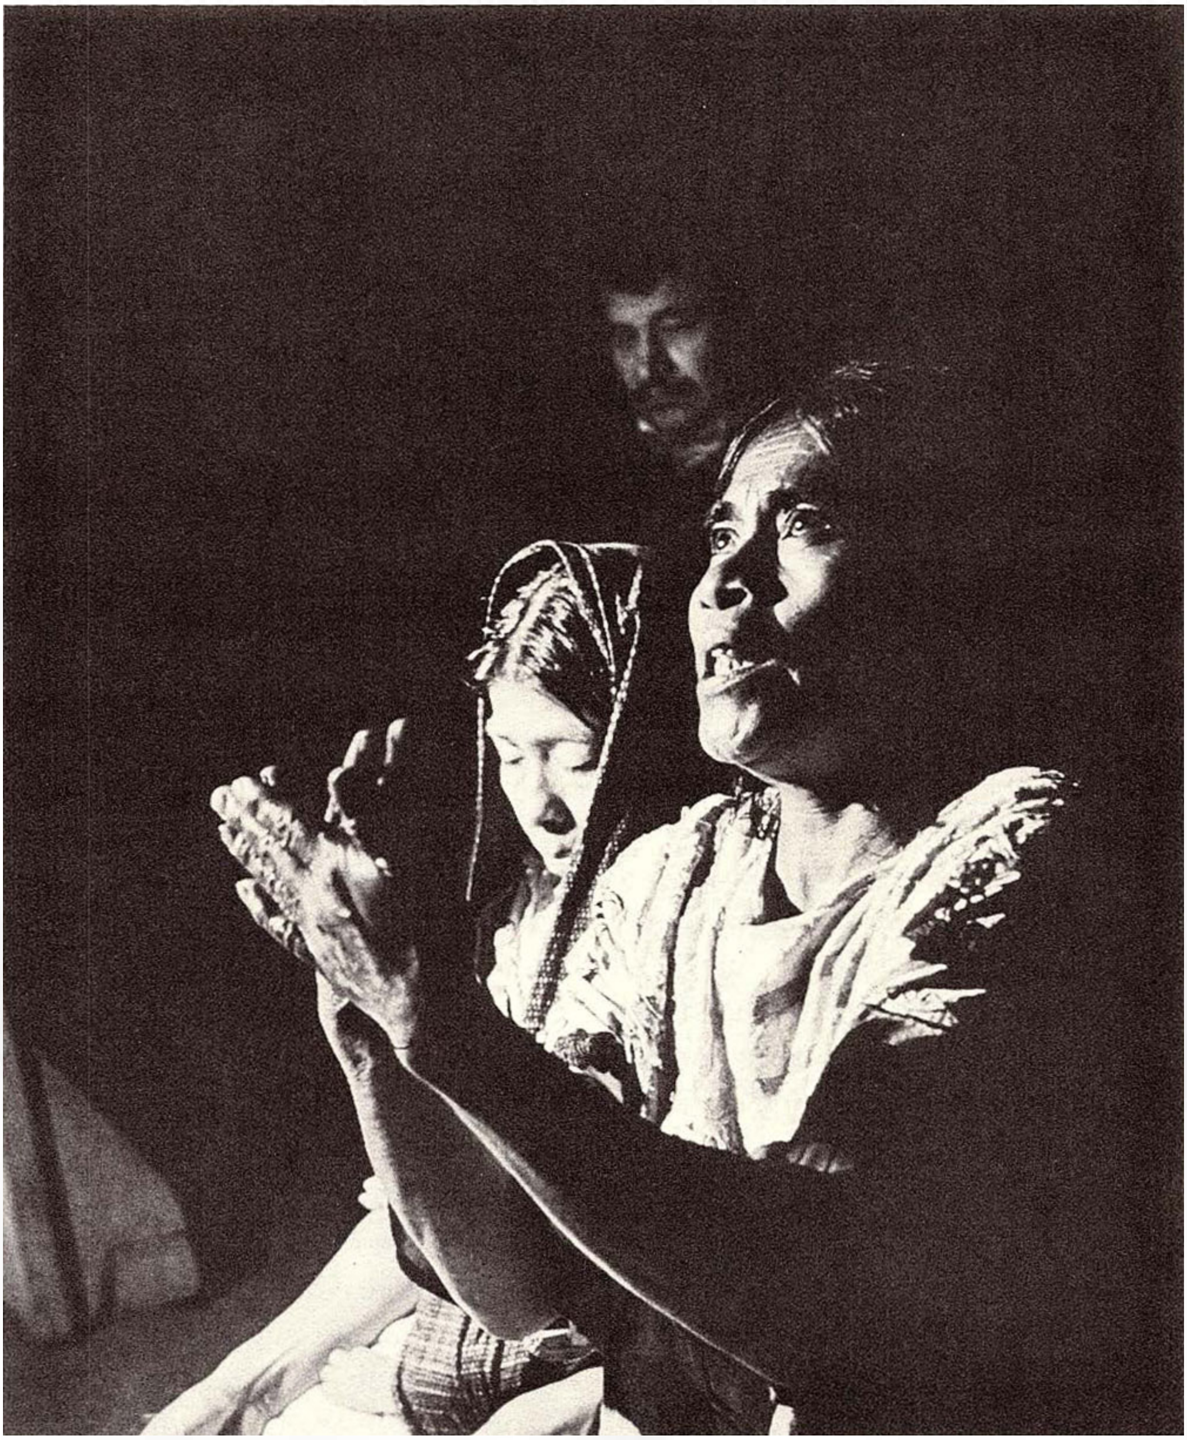

Fig 14 María Sabina invoking the Sacred Mushroom. Aurelio in background.

Suddenly in the night I made a discovery. In the light of a cigarette that someone was inhaling, I saw the Señora, who was performing her dance, lift a small bottle to her lips. From her posture the bottle seemed almost empty. A few minutes later she began to thump the butt end of the bottle on the *petate*. She did this with a fast, uniform, perfect beat, perhaps a hundred to the minute, and she kept at it for an eternity, minutes on end, until Allan and I could hardly stand it and groaned in agony. The iterated thump, somewhat resonant, became excruciatingly painful, a torture such as Poe might have described. After the night had passed and we were all getting up, I made it a point to find the bottle and smell it. There could be no doubt: it was the familiar six-ounce bottle of *aguardiente*, a distillate of cane. Presumably the Señora had shared it with her daughter, but of this we cannot be sure. We asked Cayetano about it. Yes, invariably the person who retains the Señora is expected to present her in advance with a *cuarto* (fourth of a litre) of this strong drink. We in our ignorance had neglected our duty, but Cayetano had come to our rescue. Recalling as we did how Aurelio and also our friends in the Mixe[8] country had all said that alcohol was tabu before, during, and after the consumption of the mushrooms, we are still at a loss how to reconcile the conflicting evidence. But of course the Señora's performance from first to last had differed from what Aurelio had shown us in 1953. We had now attended two all-night vigils, both using the sacred mushrooms, but otherwise utterly different from each other. Aurelio's divinatory liturgy, with the elaborate rôle in it of accessories, could conceivably go on without mushrooms, but in Cayetano's house the mushrooms were everything. We spoke to Cayetano about that other performance that we had seen in the Mazatec country in 1953. He knew all about that kind too, and he told us that the Señora was equally proficient in both ceremonies. We failed to learn, however, when one method is used in preference to the other.

At intervals throughout the night, perhaps every forty minutes or so, there would be what we can only describe as intermissions. After working up to a powerful climax in utterance, the Señora and her daughter would subside into silence. (We recall one such climax when the Señora, half singing, half declaiming, spat forth in endless repetition and with wild violence the syllable *chjon*. Afterwards we learned that this *chjon* meant 'Woman', and she was listing her own credentials as a shaman in addressing her supplications to the mushroom.) During such intermissions our two votaries and our reclining Indian friends would light cigarettes (ordinary ones) and smoke and engage in the most animated conversation. Clearly they were discussing what was happening but we had no interpreter. They would flash on electric torches. We took advantage of these moments to study the Señora. She was not in a trance. That is to say, she was one of us, talking and smoking. But she was in a state of excitement, her eyes flashing, her smile no longer that grave smile which we had observed before, but now quick with animation and, if we may use the word, *caritas*. For there is another major aspect to the mushrooms that we must mention. The spirit of an agapé of which we have already spoken was a prelude to an upsurge of generous or tender feelings that the mushrooms aroused in everyone. To illustrate this, we recall how, when nausea first sent me into the adjoining room to vomit, the Señora, who had been in full song, immediately stopped the performance, and she and the others manifested the most embarrassing (for me) solicitude about the unhappy episode, which after all was trivial. On the two nights that we passed in Cayetano's house, we were aware of no erotic stimulation among those present. But those who were present felt that we had entered into a warm bond together, by reason of the momentous night that we had spent in each other's company, and this bond I still feel. Twice in the course of that first night the Señora reached out her right hand to me and sought contact with my fingers in friendly greeting, across the chasm of the language and culture barrier. The Indians of Mesoamerica are known for their reticence in the display of affection, even within the family circle. It was now clear that the mushrooms emancipate them from inhibitions of this kind, and what we witnessed on Wednesday night was abundantly confirmed during our second session on Saturday, 2 July.

After the first performance Allan and I, quite stunned and even numbed by what we had witnessed, were disposed to say, 'Never again'. But by Saturday morning there were many questions that we needed to clarify, and so through Cayetano we asked the Señora if she would give us a repetition. This she agreed to do. We pled with her to let us take a few photographs by strobe flash while the power was on her. She said yes, and in the course of that night from Saturday to Sunday Allan took perhaps twenty pictures in the darkness, guessing of necessity as to the distance and direction. (It was raining in torrents all that night, so there was no moon.) But the Señora's behavior differed much from what we had seen the first time. Everything was reduced in scale. There was no dancing and virtually no percussive utterances. Only three or four other Indians were with us, and the Señora brought with her, not her daughter, but her son Aurelio, a youth in his late teens who seemed to us in some way ill or defective. He was now the object of her attention, not I. All night long her singing and her words were directed to this poor boy. Her performance was the dramatic expression of a mother's love for her child, an anguished threnody to mother love, and interpreted in this way it was profoundly moving. The tenderness in her voice as she sang and spoke, and in her gestures as she leaned over Aurelio to caress him, moved us profoundly. As strangers we should have been embarrassed, had we not seen in this shaman possessed by the mushrooms a symbol of eternal motherhood, rather than the cry of an individual parent. But by any interpretation this untrammeled and beautiful outpouring, incited by the sacred mushrooms, was behavior of a kind that few Middle American anthropologists would ever see.

On this second occasion Allan ingested no mushrooms, for the sake of his photography. The Señora asked me how many pair I would take, which I interpreted as a compliment to my status as one already initiated, and I

---

8. A remote people believed by some to be related to the Maya, having separated from them before the Maya culture had attained the heights that archæologists study and admire. We visited the Mixe in 1954 and again in 1959.

said five pair. The effect seemed as strong as I had experienced from the larger dose on Wednesday, but this time there was no nausea.

Our two nights with the Señora drew to a close in the same way. On the night of Wednesday-Thursday, our last notes seem to have been scribbled a few minutes before 4 a m, and soon afterwards we slipped off imperceptibly into a dreamless slumber. Apparently everyone else did likewise. At any rate, at about 6 o'clock we woke up, our heads clear. Some of the others were already stirring, and in a few minutes everyone was on his feet. I changed the roll in my camera and resumed picture-taking, as did Allan. Cayetano and Guadalupe asked after our welfare but were discreet in their inquiries about the night's doings. They served us coffee and bread. By 7 o'clock we were ready to sally forth into the world. We felt no untoward sleepiness that day.

Perhaps in some respects we can define better than we have done the psychic disturbance caused by the sacred mushrooms. On the one hand, they unhinge one's sense of time. Visions that seem to last an æon run their course in a minute or so. Only by reference to a time-piece does one keep track of the passing hours. On the other hand, the faculty of memory is heightened by the mushrooms. All the impressions, visual and auditory, are graved as with a burin in the tablet of my memory. My narrative of what took place has been checked with the notes that I jotted down at the time, but my memory is far richer and fuller than those notes.

What can we say about the source of the visions? Did they bubble up out of my own past? I have no conscious memory of having viewed previously the scenes that I saw. There was nothing in them that repeated themes familiar to me in my adult experience, no modern highways, cars, cities, no faces of friends or acquaintances. Yet all that I saw could be related to themes latent in my imagination, not necessarily things seen, nor even things seen in graphic representation, but those things transmuted afterwards in the imagination, imagined from reading, seen in the mind's eye.[9] All of the visions had that pristine quality which we associate most often with the magic of supreme literary expression, especially great poetry.

In the lives of us all, even those who are most earthbound, there are moments when the world stops, when the most humdrum things suddenly and unaccountably clothe themselves with beauty, haunting and ravishing beauty. It now seems to me that such flashes must emerge from the subconscious well where our visions have all this time been stored, for the mushroomic visions are an endless sequence of those flashes. There are those like Blake who have possessed the power to see such visions in abundance without the mushroomic stimulus. Could the mushrooms have done better by Blake than he did without them? What would they have shown him that he did not see? What precisely do our Indian friends see, with their different background? Clearly the visions come from within the beholder, either from his own subconscious or, as some will surely think, from an inherited fund of memories of the race. What an amazing thing that we should all be carrying this inventory of wonders around with us, ready to be tripped into our conscious world by mushrooms! Are the Indians far wrong in calling these divine? We suspect that, in its fullest sense, the creative faculty, whether in the humanities or science or industry, that most precious of man's distinctive possessions and the one most clearly partaking of the divine, is linked in some way with the area of the mind that the mushrooms unlock.

I have mentioned William Blake. Many years after the events here narrated I came upon a quotation from Blake that is directly relevant to this discussion:

> The Prophets describe what they saw in Vision as real and existing men, whom they saw with their imaginative and immortal organs; the Apostles the same; the clearer the organ the more distinct the object. A Spirit and a Vision are not, as the modern philosophy supposes, a cloudy vapour, or a nothing: they are organized and minutely articulated beyond all that the mortal and perishing nature can produce. *He who does not imagine in stronger and better lineaments, and in stronger and better light than his perishing eye can see, does not imagine at all*.
> [Italics mine. From *The Writings of William Blake*, ed by Geoffrey Keynes, vol 3, p 108]

---

[9] This interpretation was confirmed later by the highly significant testimony of a Mixe Indian in the Mixe country: when we asked him what he saw after taking the mushrooms, he replied that he saw Zempoaltepetl (the sacred mountain of the Mixe) open up, and on entering it he there saw paved streets lined with great houses and cars were plying back and forth on the streets. This Indian had never left the mountains where he lived, far away from highways and towns, but he had heard tell of these modern marvels.

This must sound cryptic to one who does not share Blake's vision or who has not taken the mushroom. The advantage of the mushroom is that it puts many, if not everyone, within reach of this state without having to suffer the mortifications of Blake. It permits you to see, more clearly than our perishing mortal eye can see, vistas beyond the horizons of this life, to travel backwards and forwards in time, to enter other planes of existence, even, as the Indians say, to go there where God is.

I will anticipate my story by telling here of an episode that took place in 1956, when Professor Roger Heim on my invitation had joined us. The *velada* in this case took place in a neighboring house. The effect of the mushrooms was at their peak. The Señora was singing with magisterial authority and we were all lying awake, keyed up (so it seemed to us) to the highest possible point of ecstasy. Suddenly, I do not know why, someone on one side on the room felt called upon to light a match. There was not the slightest interruption in the Señora's performance: she continued singing, clapping, gesticulating as though there was no light. But on the whitewashed wall beyond there appeared her shadow-profile, magnified perhaps by four, her triangular shape angled precisely like a Mexican pyramid, the temple on the top being the projection of her head, her gesticulations keeping slow, measured time with her singing. In the brief light of that match I was living through centuries, millennia, even decades of millennia. María Sabina was The Shaman, the focus for the woes and longings of mankind back, back through the Stone Age to Siberia. She was Religion Incarnate. She was the hierophant, the thaumaturge, the psychopompos, in whom the troubles and aspirations of countless generations of the family of mankind had found, were still finding, their relief. All this I saw in the light of that one match, in the shadow performance of María Sabina. The light of that match seemed to last an æon of time, and then, suddenly, it was out.

The mushrooms are not habit forming. They differ in this respect, not only from alcohol and tobacco, but from the drugs such as opium that are narcotics stimulating beatific dreams. In the course of our many expeditions to Mexico covering seven cultural areas, we have never heard of a mushroom addict. We believe that use of the mushrooms does not affect the threshold of tolerance for them; that is to say, one does not raise the dose on successive occasions to obtain the same effect, either for the short run as when we used them twice in four days, or over the long term. Our Señora and her daughter took more than twice the dose of the others, but that quota goes with their vocation. Everyone's dose seems to remain constant throughout life, though the dose varies somewhat from person to person. We have seen no evidence that the mushrooms can cause harmful psychic effects. Are persons with neurotic or psychotic inclinations endangered by the mushrooms? After a lifetime of use do mushroom-eating shamans show mental deterioration? May there be individuals whose mushroomic visions are horrifying and who are stimulated to violence by them? We do not know, but think not. The reports to the contrary in the writings of the early friars were prompted by their *odium theologicum*, by their own ignorance, and by their need to divert the faithful from the 'devil's food'. In considering the clinical effects of the mushrooms, let us not overlook the extraordinary performance of the Señora and her daughter. They had each eaten thirteen pair of mushrooms, as compared with five or six pair for the rest of us, and they not only kept hold of themselves: they staged a liturgy that called for disciplined virtuosity of a high order. In the mushroom season they may be called upon to perform every night.

On Friday, 1 July, Valentina Pavlovna and our thirteen-year-old daughter Masha joined us in our village. We had all planned to leave on horseback immediately after the Saturday night experience at break-of-day on Sunday, but the rains came and we found ourselves marooned among our Mazatec friends for most of the following week. On Tuesday the 5th VPW and Masha, having nothing else to do, took the mushrooms in the afternoon, VPW five pair and Masha four, and then they lay down in their sleeping bags, the doors and windows of the room closed. This was the first occasion on which white people were eating the mushrooms experimentally, without the setting of a native ceremony. They too saw visions, for hours on end, all pleasant, mostly of a nostalgic kind. VPW at one point thought she was looking down into the mouth of a vase, and there she saw and heard a stately dance, a minuet, as though in a regal court of the seventeenth century. The dancers were in miniature and the music was oh! so remote, but also so clearly heard. VPW smoked a cigarette: she exclaimed that never before had a cigarette smelled so good. It was beyond earthly experience. She drank water, and it was superior to Mumm's champagne - incomparably superior. She and Masha felt little or no nausea. Their pupils dilated and failed to respond to our flashlights. The pulse showed a tendency to slow down. But six weeks later, when I in New York took the mushrooms for the third time on 12 August, my visions were accompanied by an insistent beat with variation of pitch, perhaps an evocation of the Señora's percussive performance. The beat was not unpleasant. It seemed freighted with meaning, as though it was the rhythmic pulse of the universe. When the Señora had performed for us, we had passed most of the night in virtual darkness - an environment adapted to dilated eyes. My experience in New York took place in a room illuminated by lights from the street, and moreover on that night of the 12th a hurricane known at the time as Connie was brushing by the city. I found that the mushrooms retained their full potency in a dried state if indeed their power had not increased. I made another discovery. As I stood at the window and watched the gale tossing the trees and the water of the East River, with the rain driven in squalls before the wind, the whole scene was further quickened to life by the abnormal intensity of the colors that I saw. I had always thought that El Greco's apocalyptic skies over Toledo were a figment of the painter's imagination. But on this night I saw El Greco's skies, nothing dimmed, whirling over New York.

Now we come to the end of our initial Mazatec experience. We had agreed from the beginning to pay the Señora her usual fee for her services. We paid her fifty pesos for each night, which was somewhat more than she expected. In dollars this meant $ 4.00 a night, but in her world the fee meant much more, perhaps subjectively as much as $ 50.00 in New York. Before we left his house we asked Cayetano what we could pay him for his contribution to the success of our visit. He turned to his wife and let her speak. '*No hicimos esto por dinero*', she said, which is to say, 'We did not this for money', and they would accept none. (For those who know the Mazatec need and appetite for money this remark of Guadalupe's will indeed be amazing.) We were especially grateful to the Señora for having allowed us to take photographs by strobe flash while the power of the mushrooms was on her, during that second night. It had not been easy for her to consent to the rude, and for her, novel interruption of the flashlight. On the morning after, a messenger came to us from her. We were welcome to the pictures, she said, but would we please refrain from showing those particular ones to any except our most trusted friends, for if we showed them to all and sundry, *sería una traición*, it would be a betrayal.

CHAPTER 2

Traits of the Mesoamerican *Velada* and Kindred Topics

In the preceding chapter I have given a largely subjective account of *veladas* that I have attended. There are at least two manners of night-time divination with hallucinogens in Mesoamerica. In one the shaman casts corn kernels and by the way they fall on the cloth spread before him he learns the answers to the questions put to him. He smokes a strong cigar and to reinforce his divinatory strength he may consume mushrooms or other hallucinogens. His answers come forth after long periods of silence and as he concentrates on the questions he sweats profusely. Valentina Pavlovna and I attended this style of *velada* in Huautla on the night of Saturday, 15 July 1953, the shaman being Aurelio Carreras. Robert Weitlaner was with us, and our account of it in *Mushrooms Russia & History*, pp 255 ff, was made up from his notes and drawings.

The other manner of *velada* is sung by the shaman as we have described it in the preceding chapter. The shaman ingests the mushrooms and decides who among those present will take the mushrooms and how many pair each. There are a number of prescriptions, proscriptions, and attributes of the *velada* that I will list and discuss here.

Allocation of mushrooms

María Sabina and her daughter María Apolonia each take thirteen pair of the *derrumbe* mushrooms (*Psilocybe caerulescens* Murrill var. *mazatecorum* Heim), thirteen being a favorable number in Mesoamerica. As for her allocations to the other participants, this is based, as a rule of thumb, on their weight and their resistance to alcohol. Naturally the allocation depends on the species of mushroom. The 'landslide' (*derrumbe*) mushroom is large. The *ˀnti*^{1}*xi*^{3}*tho*^{3}, *ˀnti*^{1}*ni*^{4}*se*$^{3/4}$ (*pajaritos*, 'dear little birdies') are tiny and the dosage correspondingly bigger, perhaps twenty pair for an adult suppliant of normal weight.

'Eating' or 'drinking' the mushrooms

In every *velada* that I have attended except one the mushrooms have been eaten fresh and with only the grossest dirt brushed off. They are always ingested raw. On 5-6 July 1960 in Juxtlahuaca, in the Mixteca, the *curandera* (aunt of our host Guadalupe González) had had the little girl Juventina, youngest daughter of the house, clearly a *doncella* ('maiden'), grind the mushrooms on a *metate* (grinding stone) and catch the juice with the mushroom pulp in glasses. My companion Robert Ravicz and I drank the potion. We were told that in former times it was the custom for the *doncella* to gather the mushrooms before sunrise, when the pre-dawn breezes swept the mountain sides and dew lay heavy on the slopes. This practice seems to have died out in Juxtlahuaca, but (who knows?) it may still survive in remote *rancherías*. We were told in Tenango del Valle, in 1957, that the mushrooms could be ground on a *metate*, or (perhaps if dried) pulverized by hand, or torn to little pieces, and then drunk in pulque or *aguardiente* ('fire water'). In Tenango the mushrooms are also rubbed on an injured place in the body. In Amatlán de los Reyes, far away in the State of Veracruz but also Nahuatl country, our story teller Rufina de Jesús, on the weekend of 4-6 June 1960, told us in Nahuatl a story involving the sacred mushrooms, which we taped and filed. Later the Nahuatlato (specialist in Nahuatl) Luis Reyes, a native of that town, transcribed and translated for us her narrative and we came upon the following interchange, speaking of the mushrooms:

'Y ¿como, acaso los vas a moler?'	'And how, perhaps you will grind them?'
'No, así nada más me comeré cuatro docenas.	'No, I'll just eat four dozen. But first I will go to Mass,
Pero ahora primero me voy a misa, los llevará.'	I'll carry them there.'

I find also in my files a memorandum dated 26 June 1962 written by one of our informants for the Chinantla, himself a Chinantec, in which he quotes a *curandero* in the Chinantla as saying that 'four or five mushrooms well ground are taken in water'. I do not know how common this practice was or is among the Chinantecs.

Afterwards I came upon the pre-Conquest Nahuatl poem that starts off:

'I have drunk [*sic*] the inebriating liquor of mushrooms.'

In aristocratic circles of pre-Conquest times the mushrooms were often taken with the cold chocolate drink and mixed with maize and with flowers of *Quararibea funebris* called *poyomatli* but never with alcoholic beverages. The drinking of the crushed mushrooms seems to have been more common formerly; I am inclined to think it was the normal practice. This crushing on a *metate* supplies us with crucial evidence in favor of our obvious interpretation of the famous 'mushroom stones', as will be explained later.

Purpose of the *Velada*

A *Velada* is held in response to a request by someone who wishes to consult the mushrooms about a grave family worry. A husband may be lying sick or injured on a *petate* ('mat'): will he live or die? If he will live, what must he do to recover? What herbs must be rubbed on the injured spot, or should he eat them? What saints must be invoked? Or perhaps he must make a solemn *promesa* to go on pilgrimage (always on foot) to a specific shrine, when he recovers.

Or again the donkey has disappeared. Did he fall into a ravine and break his leg? Or was he stolen and toward which market is he being hied for sale?

Or again money hidden in the thatch of the roof has disappeared. Who took it and where is he now?

Or again a son has gone out into the world, perhaps as a wetback to the States. Neither he nor anyone else in the family can write and naturally there is no news of him. His mother worries. Is he alive or dead? If alive, is he in jail? (This question is always asked.) Is he married? Has he children? Is he well or sick? The mushroom will tell. If the question is put with a pure heart by a believer, the mushroom will not lie: so say the Indians. Only after I came to know the Indian country was it driven home to me how every Chicano falling foul of the law has a family somewhere in Mexico who cares for him and worries about him.

A *velada* must be held for a worthy reason. It will be of no help in frivolous matters or for selfish ends. Trippers who engage a shaman to hold a *velada* out of curiosity miss the point completely.

Velada essentials: 1. Darkness and isolation

One invariable rule governing *veladas* is that they should take place at night, in the dark, in a house removed from other dwellings, where quiet will reign. Noise and light severely cripple, may render useless a *velada*. The house of the shaman is usually situated somewhat apart from the village, secluded from town folk, so that the mushrooms work free of untoward interruptions. Some natural noises are not regarded as interruptions: a dog baying at the moon, the braying of an ass in the pasture, even torrential rains and terrifying thunder and lightning are not objectionable interruptions: on the contrary, these forces of nature accentuate the spell of the *velada*.

Velada essentials: 2. The monitors

At every *velada* there must be one or two persons who do not take the inebriant, whether mushroom or other, but who serve as monitors, listening to what is said, handling interruptions and intruders, seeing that no mischance overtakes anyone during the night hours in the dark. These monitors are an invariable post in the *velada* tradition. The doors are securely fastened at the outset of the *velada* and no one (except the shaman) may sally forth into the night or until the cock crows before dawn. (Once in San Andrés Hidalgo there was an exception to this rule: the door was left wide open.)

Velada essentials: 3. Prohibitions

Participating in a *velada* requires abstinence of certain kinds. From breakfast on you must fast until the night and until preparations for the *velada* are under way. Then you may drink chocolate, or nowadays coffee, a post-Conquest innovation. For four days before the *velada* you must abstain from alcohol of all kinds, from eggs, from sexual intercourse; and after the *velada* for four days more. (These four days seem to have been a basic pre-Conquest ritual pattern of Mesoamerica. I can think of no reason why eggs are banned.) A pregnant woman must never take the entheogen. If you are a novice, the shaman or your sponsor will inform you of these requirements. To drive home the various injunctions your sponsor will always have ready an admonitory tale to tell you, showing you the penalty paid once by a violator. But it is left to you whether you comply: no questions are asked. The practice reported to us from Tenango del Valle of mixing the entheogen with pulque or distilled alcohol is, so far as my experience goes, unique: it may be a legacy from the Matlatzinca (closely related to the Otomí) who once peopled this area.

The liturgy should never be sung facing the west; east is the preferred direction. Outsiders attending the rite should be as inconspicuous as possible, and silent. They should be outnumbered by natives familiar with what is going on.

The shaman's ventriloquism

A strange feature of the successful *velada* (and one mentioned also in the Siberian accounts of their shamanic vigils) is the ventriloquistic effects. Lying there relaxed in the dark, the utterance of the shaman for long intervals being the only sound, you are surprised by the changes in the direction and volume of the rhythmic song and the percussive beats. They jump, not continually, but as it were in quantum leaps, now from beyond your feet, then from above your head, from outside the hut, even accompanying you on your flight through space, again from beneath your head, whispering in your ear so close that you feel the singer's breath on your lobes buried in the softness of your sleeping bag; or again it reaches you from the depths of the earth, faint from distance. I had never before noticed the difference in the quality of sounds of equal volume - a whisper in the ear and the same voice diminished by distance from the bowels of the earth: the two sounds seem worlds apart.

Gonzalo Aguirre Beltrán in his invaluable *Medicina y Magia* has combed the manuscript sources in the Archivo General de la Nación for documentary evidence of practices in the seventeenth century revealed in the Proceedings of the Inquisition bearing directly on our subject. (His work is indispensable as a point of departure for anyone exploring this field.) Concerning the ventriloquism he suggests that it was introduced by the post-Conquest Negro immigration from Africa. But he is mistaken. The hallucinogens contain within themselves the agent that, working in the inner ear, produces this startling effect. Here is the perfect example of the weakness of research done in the study to the exclusion of field experience. Had Aguirre Beltrán attended *veladas* in the Indian country surrounding Mexico City and had he ingested the entheogens, his observations on ventriloquism would have been utterly different.

In my first *velada* with María Sabina I had been puzzled by the ventriloquistic effects and had gradually come to tentative conclusions, but the darkness made it difficult to be certain. Later an opportunity presented itself. On Monday 12 June 1960 we found ourselves in Huautla when word reached us from Herminio Figueroa of San Andrés Hidalgo that his neighbor the *curandero* Crescencio Martínez would serve us that very night. Irmgard Weitlaner Johnson, Herlinda Martínez Cid, and I forthwith set out walking, our sleeping bags and other impedimenta being carried by two young boys. Herminio was the nephew of Herlinda, and his grandfather, the shaman Manuel Figueroa, had taught don Crescencio his art. We found Crescencio waiting for us in his house somewhat removed from the village. Of middle age, he spoke not a word of Spanish. We passed the night with him, he reciting (not chanting) prayers in a low, clear voice. The night was clear, the stars and Milky Way were brilliant. Whether there was a moon I do not remember. The light shone through the open door and one could make out the people and objects in the room. Here then was my opportunity. Irmgard and I, after ingesting the mushrooms and after they had taken effect, both observed a powerful ventriloquistic result. (They were '*derrumbes*', my quota being six pair, Irmgard's four, and the shaman's nine. Irmgard did not find the mushrooms disagreeable or nauseating.) I was in a relaxed trance, the voice, distinct and crisp, coming at me from different directions in succession, in different volume. I had only to open my eyes to see the shaman on his little stool before the dead or dying fire. To shake off my trance I would seize some wooden struts that lay to hand and reach for the wall: there was a touch of nausea and then I was in full possession of my faculties, my eyes open and all ventriloquism gone, and I would see and hear don Crescencio saying his *oraciones* in his natural voice. Again I would let myself sink back into trance. The voice once again would flit from place to place. I did this several times: don Crescencio was unaware of my surveillance.

Irmgard later told me what had happened to her: she had suddenly felt with a start that the singing was close by, the singer bending over her. She quickly and quietly turned, her eyes now wide open, only to discover that he was seated on his stool by the fire some seven feet away, paying no attention to her.

The designation of the shaman

Mesoamerica is a complex of related and unrelated languages, but through them all the same metaphorical meanings seem to prevail. Thus 'shaman' in classical Nahuatl is '*tlamatini*', in Mazatec *cho*^{4}*ta*^{4}*chi*^{4}*ne*^{4}, and in the Zapotec of the Sierra Costera *mènjak*.[10] All of them mean 'one-who-knows'. These terms are broader than 'shaman': they include the herbalists and formerly the priests of the native religion. It would be important to learn how far this 'one-who-knows' extends, and whether it may not reach beyond Mesoamerica, possibly everywhere in the Americas of the Indian, perhaps in Siberia too. The Mazatec and Zapotec terms have another thing in common: they are not nouns like 'shaman'. They are verbal phrases and they conjugate and decline depending on the meaning to be conveyed. In Zapotec for example *sanjak* is 'that man knows' = 'that man is a shaman'. These terms of respect in the linguistic subcultures of Mesoamerica correspond to 'Wiseman' or 'Soothsayer' used long ago among our own remote cultural ancestors for the *élite* of their unlettered world. 'Witchdoctor' is a contemptuous name for the wiseman invented by the white man.

In María Sabina's mind those who follow her calling are sharply divided into three categories. She is a *cho*^{4}*ta*^{4}*chi*^{4}*ne*^{4}, 'one-who-knows', a *sabia* ('wisewoman') in Spanish, and belongs in the highest class. She says she cures by the mushroom alone, the mushroom serving for diagnosis and guidance in treatment. She has never used her power for evil. In the second class is the 'healer', *cho*^{4}*ta*^{4} *xi*^{3}*v*^{ʔ}*e*^{1}*nta*^{3}, which means 'one-who-builds'; he is the *curandero*. He uses massage with *pisiete* (*Nicotiana rustica*), also potions with incantations, invoking the spirits of well known mountains, neighboring springs, and other holy places. The third class is the *tji*^{2ʔ}*e*^{2}, in Spanish *brujo*, *hechicero*, or *zahorí*, in English the sorcerer or witch. In María Sabina's mentality this is a class of practitioners who use their magical powers only to work evil. Whether such a tripartite grouping is exclusively María Sabina's or whether it is held by Mazatec *sabios* generally, or whether it is even more widespread having until now escaped detection by anthropologists, we do not know. There must be elasticity in these categories. We know for example that in Mesoamerica there is a technique for curing by 'sucking out the evil', which is practiced by the second category. Some *curanderos* apply their lips directly to the spot on the body where they think the sickness or injury lies and suck audibly. Some interpose between their lips and the place on the body a *carrizo* or tube made of a reed, and then suck. Others suck audibly without moving from their position and María Sabina is one of these. This sucking is the act of a *chupador*, and from our own tape recordings we know that María Sabina is a *chupadora*. Many *chupadores* are prepared to show those in attendance the object(s), whether animate or inanimate, that they have sucked from the body. Belief in the *chupador* is old and widespread: it has been traced across much of Eurasia. Someone has asked whether this could have been the ancestor of 'cupping'.

Now we come to the individual names of shamans. There was a famous shaman in Santa María Huitepec in the Mixería, whom the Mixe called *Pe:t Munt* in speaking with us. In Spanish this would be plain 'Peter World'. But in Mixe his cognomen was *Na:šwin*, meaning 'World' or 'Universe' and for the Mixe carrying a potent mystical idea. It seems to me unlikely that he was given this name in babyhood. It must have been assumed when in his career he reached a point where his quality justified the new name, just as do the actors in Japan when they assume the name of a great predecessor on attaining his stature in the profession. In San Pedro Nexapa we made the acquaintance of Marina Rosas, a Nahuatl shaman. In sixteenth century Spanish *rosa* was a synonym for 'flower' and thus 'Rosas' means 'flowers', translating *xochitl* in Nahuatl, a word weighted with all the magic of the entheogens, as will be demonstrated in the next chapter. In Mexico City I have met those who assert with assurance that 'Sabina' is borne by María Sabina because she is a *Sabia*, a 'Wisewoman', but this turns out to be impossible because Alvaro Estrada has found her baptismal record in the parish register of Huautla and there she is entered as having been baptized 'María Sabina' in infancy. María Sabina's maternal grandfather and great grandfather, and a granduncle and a grandaunt, were famous shamans, and the only possibility is that she (as well perhaps as Marina Rosas) was dedicated to her calling by her parents and then grew into the shaman that they were hoping for.

---

10. In our spelling of Zapotec words there are three tones: high represented by ', low by `, middle without accent. 'J' is pronounced as in 'judge'. An apostrophe, ', means a glottal stop, as in the Scottish pronunciation of *bott'l*.

The sacred mushroom: the 'small fry' or 'little tykes'

Across linguistic lines throughout Mesoamerica the sacred mushrooms are called 'little children' by names that are always both affectionate and respectful.

Marina Rosas of San Pedro Nexapa, a village in the direction of the Paso de Cortés and near the great volcanoes, in the heart of the classical Nahuatl country, spoke of the mushrooms as *a-pipil-tz-in*, the 'little children of the waters'. She is a *sabia*. In Tlanixco, a village near Tenango del Valle, in a Nahuatl-speaking district, the divine mushrooms known to the villagers are called *mujercitas* (= 'little women') or *señoritas* (= 'young ladies') or *niñas* (= 'little girls') when they use the Spanish words, and when speaking of the sacred mushrooms in general, they say *niños* (= 'children'). The sacred mushrooms are always paired off with *Cordyceps capitata* growing on another fungus, *Elaphomyces granulatus*, and this Cordyceps is the masculine element: it has no hallucinogenic potency whatever but is strikingly phallic in appearance. In Nahuatl the townsfolk of Tlanixco call these mushrooms *nanacatzintzintli*, a word that is pronounced hesitatingly and only in a whisper, and that simply means the 'dear and venerated little mushrooms'. In Amatlán de los Reyes, a village in Veracruz where Nahuatl is also spoken, the sacred mushrooms are spoken of by either of two names:

tlacatzitzen, or = little men
chocotzitzen = little children

María Sabina in Mazatec sings of the *ˀnti^{1}xti^{3}*, the *niñitos*, 'dear little children'; and also of the *sa^{4}se^{1}*, the *payasos* or 'clowns', the *ˀnti^{1}tso^{3}jmi^{2}*, the *cositas* or 'little things'; also of the 'little nuns', uttered with caressing love and reverence, little creatures (they tell us) the size of mushrooms and up to all sorts of tricks. The names for the mushrooms are all evasive. María Sabina never uses in her chanting the most holy name of all, *ˀnti^{1}xi^{3}tho^{3}*, 'the dear little ones that spring up', and when in conversation she does so, she lowers her voice as though it were too holy to utter, although this is obviously an evasive term for a prior name now forgotten.

In the Zapotec country we learn from Thomas MacDougall that the entheogenic morning-glory seeds, *ololiuhqui*, are ground on the *metate*, the resulting flour then poured into water, the solid particles strained out, and the cold liquid drunk. A little girl, *una doncella*, serves the drink to the patient. The seeds number either seven or fourteen or twenty-one. A *curandero* or a friend is present to watch over the proceedings and note what is said. Solitude and silence are essential, and without them the *badu-win*, two little girls dressed in white, will not appear. The seeds of *Turbina corymbosa* (formerly *Rivea corymbosa*) are called *badoh*, and the alternative stronger seeds of *Ipomæa violacea*,[11] either *badoh-negro* or by their full rendering in Zapotec, *badungás*. (We visited the Zapotec country early in our Mesoamerican peregrinations and did not know enough to ask about the tiny folk evoked by the entheogens but we did learn that the morning-glory seeds are called by the same name as the sacred mushrooms, *mbèydó*.) The two little girls are evoked by the accepted entheogen, whether mushroomic or other.

In the Chinantla Arthur J. Rubel reports that when the mushrooms take effect, children, boys and girls, appear. In Rubel's *velada* only the shaman ate the mushrooms. Professor Rubel sent me samples of the mushrooms and Roger Heim's laboratory identified them as *Psilocybe hoogshagenii*.

The Matlatzinca, once a numerous people living to the west of Mexico City, are now reduced to about 2,500 in a single village, San Francisco Oxtotilpan. They still speak their own language belonging to the Otomí linguistic stock. In Spanish the sacred mushrooms are called by them the 'little saints', *santitos*. To one who has eaten them the *santitos* appear as tiny beings the size of playing card kings. This we learn from the study of Roberto Escalante of the mushroom vocabulary in the language of the Matlatzinca. The old name in the Matlatzincan language is *neto&ccaron;^{h}utata*, *ne-* being the plural, *-to-* a reverential diminutive, *-&ccaron;^{h}u-* the root for sacred, and *-tata* being lord: 'the most holy little Lords'.

---

[11] In *Medicina y Magia* Aguirre Beltrán calls attention (p 136) to the use of the adjective *moreno* with *ololiuhqui*, 'black morning-glory seeds', and thinks that the seed grows black with age. But they do not change in color with time. When he worked on his excellent book we were just learning of *Ipomæa violacea* whose seeds are black and more powerful than those of *Turbina corymbosa*. Both are morning-glories.

In the Mixe country Searle Hoogshagen reports that the sacred mushrooms, when consumed under the proper circumstances and in the right number (all as we have said), put one in a trance whereupon little men known as *los Señores* emerge and deal with the problems that concern you.

The mushroom 'speaks', not the shaman

A feature of the Mesoamerican *velada* is that the mushroom is thought to speak through the voice of the shaman who is merely the conduit for the utterances of the mushroom. We recall the words of Aurelio Carreras: the mushroom *es habla*, 'is the Word'. Verses ending with *tso*^{2} in the Mazatec *velada* are not the shaman's, they are the mushroom's: *tso*^{2} means '[he] says'. From Siberia we learn that this is the way with the mushroom there: it speaks, it utters the Word. The first impression of Westerners with the mushrooms seems generally to be different: they are struck, often stunned, by the kaleidoscopic shapes that they see in the darkness, eyes open or closed. The voice is secondary to the visions. But the testimony of the Indians, including the shamans, on this is conclusive: the *Word* is the thing, just as in Sanskrit it is the *Văc* and in Greek the *Logos*.

Antiquity of mycolatry in mesoamerica

The records of the past in Mexico are uneven, areas of brilliant illumination alternating with others that run all the way to darkest night. The widespread use of inebriating mushrooms in Mesoamerica, rediscovered and for the first time explored in our own day, is cursorily documented in the sixteenth and seventeenth centuries in the writings of the friars and parish priests of that time, and also in the somber Proceedings of the Holy Office of the Inquisition. Before then for the shamanic use of mushrooms there is nothing. True, such evidence might compel alert scholars to postulate a widespread ancient use of entheogenic mushrooms. But this evidence, strong though it may be, is immeasurably broadened and strengthened by the shamanic performances that still survive throughout the highlands of southern Mexico. These survivals permit us to gain a perspective on the antiquity of the use of the mushrooms. María Sabina's chants in the Mazatec country and Aristeo Matías' far away in the Sierra Costera in Zapotec country, linguistically far removed from each other, seemed to me (as I wrote down at the time and we suggested in *Mushrooms Russia & History*) musically the same. I taped María Sabina's singing but did not tape Aristeo Matías'.

Moreover, María Sabina's Mazatec liturgy and the liturgy that we discern in the writings of Ruiz de Alarcón in the early seventeenth century for the Nahuatl world are unmistakably founded on the same oral traditions. I have documented these parallels in *María Sabina and Her Mazatec Mushroom Velada* and will not repeat the demonstration here. With these benchmarks we may legitimately triangulate deep into Mesoamerican prehistory to arrive at the age of the divinatory mushroom rite. (We must always keep in mind how slowly cultural changes took place in proto- and prehistory.) When words and music are so wedded that the words cannot be divorced from the melody, nor the melody from the words, as with the ṚgVeda hymns and the chants of the Mesoamerican *velada*, we possess in these verbalized musical expressions probably the most ancient of surviving anthropological evidence. It takes only a modicum of historical imagination to perceive a shamanic tradition invoking the mushrooms reaching back for millennia, probably back to Siberia and the cult that survived there until only a few years ago. And this tradition is buttressed on either hand by the same little tykes and clowns and tricksters tumbling around and then, on request, coming and speaking with the voice of authority to us through the shaman, precisely as in Siberia.

A question of grammar

But for the antiquity of the entheogenic mushroom use we are not confined to the living chants and Ruiz de Alarcón's writings: the very grammar and usages of the native languages through fossilized forms testify to it.

In Nahuatl, the language of the Aztecs and all other Nahua, nouns representing inanimate things are invariable as to number. There are seeming exceptions of which here are three:

	Singular	*Plural*
Sky	*ilhuicatl*	*ilhuicame*
Mountain	*tepetl*	*tetepe*
Star	*citlalin*	*citlaltin*

These exceptions are apparent rather than real, for the Nahua personified the sky, mountains, and stars, and the plural form simply expresses the way of feeling that attributed to these cosmic beings a soul. Other exceptions are similarly suggestive. For example, *tetl*, 'stone', becomes *teme* in the plural, but only when it refers to graven images.

For the Nahua the whole vegetable kingdom is construed as inanimate and therefore all herbs, shrubs, and trees are invariable as to number. Grammarians say that there *may be* one exception: 'mushroom' is *nanácatl* and this could be the plural form for *nácatl*, 'flesh'. Grammarians concede this much but their discipline does not permit them to go further. I am prepared to advance ethnomycological background supplementing the data of the grammarians and converting what they say is, grammatically, a possibility into virtual certainty. The sacred mushrooms, possessing a soul, are responsible for the plural shape of *nanácatl*.

In many languages the mushroom vocabulary includes a generic word for that which is eaten - 'meat', 'bread', 'cheese', 'flesh', and 'food' itself. Thus in dialectal English we find 'toadsmeat' and 'toadscheese'; in Norman French, *pain de crapaud*, 'toad's bread'; in Dutch, *duyvelsbroot*, 'devil's bread', which in classic Latin becomes *cibus deorum* and in Greek *br&omacr;ma the&omacr;n*, 'food of the gods'. (As the Greeks were mycophobes, the 'food of the gods' gave the mushroom an exalted tabu status that served to exclude men from eating it.) In Pashto, a major Indo-European language of Afghanistan, *pocəkəí* is the name of an important edible mushroom and that name means 'flesh', the same meaning that appears in Nahuatl *nanácatl*. Of course we are not suggesting a genetic kinship of these words with Nahuatl but when we come upon a simple figure of speech in a mushroom vocabulary and find a parallel association of ideas in other languages, a pattern of human thinking begins to emerge. *Nanácatl* is built on *nácatl*, the word in Nahuatl for 'flesh', a generic metaphor like 'food', 'victuals', 'bread', 'meat'; and by doubling the initial syllable it assumes a pluralized form that gives to the mushroom a soul, a status unique in the vegetable world. All mushrooms - *nanácatl* - are endowed with a soul, a unique status granted to the non-hallucinogenic species by reason of their kinship to the divine kinds, the divine kinds dominating by their overwhelming importance the whole fungal world. The root meaning, 'flesh', is emotionally colorless, neutral (like eg 'meat', 'bread', 'cheese' as given above), but it becomes exalted when the plural form - *nanácatl* - is preceded by *teo*- or *xochi-*, the designation of the entheogenic kinds.

There is a striking parallel in the Santal language, a non-Indo-European tongue spoken by a tribe scattered in villages in Orissa, Bihar, and West Bengal. In Santal as in Nahuatl, the whole of the vegetable kingdom is viewed as inanimate, but in Santal there is a startling exception: a single species of mushroom, the *putka*, which is animate and being animate possesses a soul. I made a preliminary visit to what are called the Santal Parganas in 1965 to inquire about the *putka*. Again in 1968 Roger Heim from Paris and I from New York journeyed to Orissa and Bihar for the express purpose of studying this mushroom, which Professor Heim identified, but no one could remember why it alone of the mushroom tribe was animate! It is not entheogenic and in the season when it abounds is much eaten with rice. Professor Stella Kramrisch in a paper resulting from our inquiry arrived at the etymology of *putka*: not of Santal origin, it is a loan word from the Sanskrit *p&umacr;tika*, the first surrogate for the Soma of the Vedic hymns, a loan word that survives to this day only in Santal and possibly other tongues of the Munda family. (Mayrhofer, compiler of the recent *Concise Etymological Sanskrit Dictionary*, has referred to the Kramrisch explanation in the addenda to his lexicon.) Thus the parallel with Nahuatl is close: the divinity that glows in a mushroom, in each case, gives to the mushroom a soul; in one instance (Santal) the specific kind, in the other (Nahuatl) the whole tribe of mushrooms embracing perhaps a score of entheogenic species.

An arresting grammatical status for mushrooms exists also in certain Slavic languages. At an early stage in the evolution of the Slavs there developed a tendency to substitute the genitive case for the accusative when a masculine noun representing an animate creature was the goal of the verb. In folk Russian this genitive is used not only for nouns denoting animate beings, but also for the names of various mushrooms and for the oak, when the mushroom or tree is individualized, *ie* is a single entity.[12] This use is widespread in Russian dialects, and occurs also in Ukrainian and White Russian. One hears *nashol griba*, 'he found the mushroom', with *griba* in the genitive case; *nashol grusdja*, *ryzhika*, *borovika*. Among the trees the oak is especially favored by similar treatment, *eg*: *srubil duba*, 'he chopped down the oak'. The oak used to be worshipped in pagan times by the eastern Slavs as the thunder tree dedicated to the god Perún. Thus in the folk language certain mushrooms attract a grammatical expression of the animism that survives from prehistory. It is possible to offer yet another example in Russian. In the standard language the mushroom known as the *masljenik* has a special plural form, *masljata*, and the plural of another mushroom name is *opjata* in certain uneducated circles. The plural suffix here used is normal only with certain nouns designating young animals, birds, and children!

---

[12] For guidance on this feature of Russian grammar see A. A. Shakhmatov's *Kurs Istorii Russkogo jazyka*, St. Petersburg, 1911, Vol 3, p 338. We are also indebted to Roman Jakobson for his elaboration of the same theme in private correspondence.

Clearly this personification of the divine mushrooms is a fading survival from the time in prehistory when the northern Slavs knew the virtues of entheogenic mushrooms. Professor Marija Gimbutas, the renowned Lithuanian prehistorian, has reported to us on the use down to our own day of *Amanita muscaria* (*ie* 'Soma') in the remoter parts of Lithuania at wedding feasts and the like when the mushrooms were mixed with vodka, and also how the Lithuanians used to export quantities of *A. muscaria* to the Lapps in the Far North for use in their shamanic practices. Here in the Lithuanian festivities is the only report that I have so far received of the ingestion of the fly-agaric in Eastern Europe for jollification ends. Early Man survived longer in Lithuania than almost anywhere else in Europe.

These parallels in unrelated languages and cultures reinforce each other and drive home the powerful spell (sometimes reaching to divinity) that the entheogenic mushrooms cast over diverse peoples in prehistory.

'God's flesh'

As we have seen on p XVII, Motolinía in the sixteenth century said that *teonanácatl* meant 'god's flesh' and this has been widely accepted ever since as its meaning. But Thelma Sullivan in a closely reasoned personal communication (13 May 1975) has demonstrated to me that that translation is wrong. The teo- of *teonanácatl* means divine or wondrous or awesome, and so *teonanácatl* means the divine or wondrous or awesome mushroom, nothing more and nothing less. This adjective *teo*- cannot be construed as the genitive - whether objective or subjective - of 'god'. Motolinía was overreacting: he gave the word a meaning with a direct bearing on the Elements in the Mass, a theological meaning that sacrilegiously and blasphemously (as he saw it) set the mushrooms up in competition with the body and blood of Christ, in competition with the bread and wine of our Christian sacrament. The sixteenth century Spanish friars arrived in the New World encumbered with the theological baggage of their place and time and they saw *nácatl* as an appalling simulacrum of the Eucharistic sacrament rather than a colorless word for the texture of the fungal flesh. That innocent word suddenly became charged with the high voltage of sixteenth century *odium theologicum*. Motolinía's mistake was shared by the clergy of his time: given the doctrines prevailing in the Catholic world, their mistake was natural. In 1537 it finds expression in the Proceedings of the Inquisition, and in the mid-seventeenth century in the writings of Jacinto de la Serna. The leading Nahua, not grasping the theological affront that this innocent term, misinterpreted, carried to the Christian hierarchy, must have quailed at the fury of the friars over their *teonanácatl*.[13] No theologian seems to have challenged this meaning and we have had to wait four centuries until a grammarian and an ethnomycologist have clarified the confusion. The Nahua from their position of weakness would not have dared to argue their case and the friars with the passing generations have thrust their erroneous interpretation on the Christianized Indians.

But though the friars were wrong in saying that *teonanácatl* meant 'god's flesh' (*carne de dios*), they did indeed find the Mesoamerican Indians adoring mushrooms that could lift them to a superior world where, for the nonce, they were on a level (as they thought) with the gods; where the Greeks were when they drank the potion at Eleusis, and where the Aryans were after ingesting their *amrita*. What a strange confrontation, the sixteenth century friars facing the Wisemen of a culture of Early Man who possessed a secret far older than theirs, neither group understanding the other but the Spaniards backed up by the grim secular arm of the Inquisition.

---

[13] In sixteenth century Mexican writings I have found the word *teonanácatl* only twice, in Motolinía and Sahagún. But it still survives: priority goes to Gastón Guzmán Huerta, Mexican mycologist, for having rediscovered it. In August 1958 in Necaxa, Puebla, he heard Nahuatl speakers using *teotlaquilnanácatl* for the enrheogenic mushrooms. (*Ciencia*, Mexico, 20: 3-4; pp 85-88; 10 June 1960) Thelma Sullivan suggests as a possible translation the 'divine sunset mushroom'. On 19 Sept. '72, Irmgard Weitlaner Johnson, Guy Stresser-Péan, and I learned in Xolotla, Puebla, from a shaman of prestige, Bernardo de la Cruz Tecalco, that the sacred mushrooms are known there as *tenanacatzitzi*. The *te*- is the eroded *teo*- and the suffix - *tzitzi* is a diminutive of reverence and endearment.

The mazatec mushroom world

In the Mazatec world the sacred mushrooms also enjoy a unique status but it is verbal and not grammatical. The word for 'mushroom' in Mazatec is *thain*^{3}, in which the t is aspirated, the vowels are nasalized, and the word is pronounced in the third tone. The word covers the whole of the mushroom world - edible, inedible, poisonous, whether growing in the earth or on vegetation. It includes the whole mushroom world except the sacred mushrooms. The sacred mushrooms are ^{2}*nti*^{1}*xi*^{3}*tho*^{3}, an arresting expression. The initial syllable is a particle expressing endearment and respect. The rest of the word means 'what leaps forth'. I have already rendered the whole: 'the dear little tykes that leap forth'. In her first letter to me, 9 March 1953, Eunice V. Pike gave me this Mazatec term and added that she could not explain it. But Early Man, as I well knew, always perceives that mushrooms do not grow from seed, and it seemed to me that the miracle (as Early Man construed it) of their birth found expression in this term. Some months later, when we entered the Sierra Mazateca for the first time we found that our muleteer Victor Hernández had travelled the mountain trails all his life and spoke Spanish though he could neither read nor write nor even tell time by the clock's face. As we were making our way out of the mountains after our visit, we asked him why the mushrooms were called 'what springs forth'. His answer, breathtaking in its spontaneity, its sincerity, was filled with the poetry of religion, and I wrote down what he said word for word as he uttered it:

> El honguillo viene por sí mismo, no se sabe de dónde,
> como el vienro que viene sin saber de dónde ni por qué.
>
> The little mushroom comes of itself, no one knows whence,
> like the wind that comes we know not whence nor why.

My interpretation had found confirmation in Victor's words. Almost a quarter of a century later María Sabina, in her story of her life, dictated in Mazatec to Alvaro Estrada and translated by him into Spanish, disclosed in an extraordinary passage how always present in her mind was the wonder of the birth of the sacred mushrooms. In reading her words we must remember that in the Mazatec mind the sacred mushrooms have sprung, not from seed (which of course they do not possess), but from the falling drops of Christ's blood or spittle. In what she says she is impersonating the sacred mushrooms.

> Las cositas son las que hablan. Si digo 'Soy mujer que sola caí, soy mujer que sola nací,' son las cositas quienes hablan. Y dicen así porque brotan por sí solas. Nadie las siembra. Brotan porque así lo quiere Dios. Por eso digo: soy la mujer que puede ser arrancada, porque las cositas pueden ser arrancadas... y ser tomadas... Deben ser tomadas tal y como son arrancadas... No deben ser hervidas ni nada. No se les necesita hacer nada. Como son arrancadas así deben ser tomadas... con todo y tierra. Deben ser comidas por completo, porque si se tira un pedazo, los honguitos preguntan en la velada, '¿Donde están mis pies? ¿Porque no me comiste por completo?' Y ordenan, 'Busca el resto de mi cuerpo y tómame...' Deben obedecerse las palabras de las cositas. Habrá que buscar y tomar entonces los pedacitos que no fueron comidos antes de comenzar la velada.
> [Estrada: *La Vida de María Sabina*, pp 82-3]
>
> The *little things* [sacred mushrooms] are the ones that speak. If I say, 'I am the woman who alone came down, who alone was born', it is the *little things* that speak. And *they say so because they sprout by themselves. No one sows them. They sprout because God so wills*. That is why I say: I am the woman who can be pulled up, because the *little things* can be pulled up... and be taken... They should be taken just as they are pulled up... They should not be boiled nor anything. There is no need to do anything. As they are pulled up, so should they be taken... with dirt and everything. They must be completely eaten, because if a piece is thrown away, the *little things* ask in the *velada*, 'Where are my feet? Why did you not eat all of me?' And they command, 'Find the rest of my body and take me...' The words of the *little things* must be obeyed. Then you must look and find the pieces that were not eaten before the *velada* began.

The art of the mushroom *velada*

A salient fact about the sacred mushrooms has almost escaped remark up to now: the beginner gives the appearance of one drunk and this may easily outlast several trials. But then by dint of practice he takes hold of himself and discovers that he is able to time his movements, his thoughts, his impressions, under the guidance of the shaman. Finally he achieves complete self-control. He learns until he and the mushroom perform in harmony. María Sabina, after taking thirteen pair of the big *derrumbe* mushroom, goes through a four or five hour performance as taut as a violin string, every note, every motion, timed to a nicety. She neither stammers nor stumbles.

Listen now to what the Zapotec shaman (= *mènjak*) Aristeo Matías told us when we asked him what we should do to learn the secrets of the shaman and become one. His answer was a disquieting parable, telescoping the apprenticeship into four stages:

> On taking the mushroom for the first time the mushroom introduces himself to the novice: *Así me llama yo* ('thus am I called'[14]). Then terrible things happen but be not afraid. You rush to the sea, you plunge in, you go up to heaven, there where Jesus Christ is, and then to hell where the malefactors are. You see the whole world lying in the middle of the sea. On the second try you are thrown into the sea, but be not afraid. Then you see two women and two men who are gathering up the blood where Christ was born [*sic*]. On the third try everything changes, and now you are strong and the voices begin to come. Then, on the fourth try you arrive there where the Virgin Mary is, and the Lord Jesus Christ, and then they explain good things. Then all the Spirits come, all the Virgins, all the Saints. Then you know and are a *mènjak*. From that moment the mushroom teaches you all things.

Aristeo was voicing a mystical picture. He was describing the confusion - even panic - felt by the novice on first taking the mushroom, and how after many tries and after weathering many storms (divided into the four stages) the aspirant might finally reach his goal, become *one-who-knows*.

The shaman, as also his tiny flock of tried participants, has weathered the initial chaotic and troubling effects. They and the mushrooms consider themselves a brotherhood. Henry Munn describes the effect in his unpublished essay on María Sabina, laying stress on the powerful, all-possessing rhythmic beat that sweeps over not only the shaman but the whole gathering. His description, which he permits me to quote, is utterly different from mine and equally valid:

> Throughout the 1958 *velada* [of the shaman María Sabina] the image of an old eagle always occurs in association with a watch. 'Woman-watch am I, / Primordial Eagle am I'. I submit that the watch is an image for the clockworks of consciousness, the minute wheels and springs of the cerebral machinery, which under the mushroom influence can even become acoustic in the ticking heard in the inner ear. The image of the watch, recurring throughout her chants, introduced by María Sabina from the world of technology, expresses by metaphor the neural, cellular, biochemical processes revealed by psilocybin, which not only manifest the mind but the dynamic, rhythmical functioning of the whole body. 'Woman-watch am I', says she. The microscopic machinery, the clockwork of the cells with its fine timing, is what she means, the complex, infinitely mysterious, marvelous workings of the human cerebrum and nervous system. Images such as these do not come from knowledge but from the phenomena themselves. It is as though the mind senses by intuition its own nature by metaphor, in advance of science... These are transcendental themes, in which one has a sense of flight through the air. This is what she means by the ancient eagle, the celestial bird... [Under the influence of entheogens,] many feel as though they are rushing through the air, riding a great bird with wide wings, whirling high in the sky in wide gyres, looking down on the earth far below.

---

[14] Note the parallel with Exodus 3:14: 'And God said unto Moses, I AM THAT I AM; and he said, Thus shalt thou say unto the children of Israel, I AM hath sent me unto you.' It is incredible that Aristeo was familiar with this Bible passage.

In Munn's words we catch the voice of proto-history, of prehistory: the shaman and his flock, having taken the mushrooms, lifted to skies of ecstasy, translated from our world to the pure empyrean, throbbing with the beat of the universe.

Since that night of 29-30 June 1955 in Huautla many Westerners have attended a Mesoamerican *velada* and many of them have ingested the mushrooms or morning glory seeds. Many others without attending a shamanic session have tried the entheogens. Even artists have sometimes tried the mushrooms to see whether their creative faculties would be heightened. These are all mere novices. We must remember the words of Aristeo Matías and know that to cope with the mushrooms one must survive one's astonishment and take them repeatedly to work in beat with them under the shaman's guidance. Thrill-mongers debase the mushrooms and themselves. In María Sabina's *velada* we are permitted to sense one aspect of religion as it irradiated the lives of our remote ancestors during millennia in our own prehistory. The Indian believes in the mushrooms, believes that in the course of these *veladas* he is granted what we call extrasensory perception, what he views as divine guidance. Can we be sure he is wholly wrong? I do not profess to know. But to dismiss these beliefs out of hand is, clearly, a sign of intellectual arrogance born of ignorance.

When Alberto Ongaro inquired of María Sabina how she became a shaman, she gave an answer in equally poetic language but subjective and personal:

> The secrets that the mushrooms revealed to me are enclosed in a big Book that [the mushrooms] showed to me... My sister Ana María [years before] fell ill... I loved my sister and I took many, many more [mushrooms] than I had ever taken before. My soul was entering the world of the mushrooms and I was seeing landscapes in the deepest depths of their world... At one point a sprite came toward me. He asked a strange question, 'But what do you wish to become, you, María Sabina?' I answered him without thinking that I wished to become a Saint. Then the spirit smiled and immediately he had in his hands something that was not there before, a big Book with many written pages. 'Here', he said, 'I am giving you this Book so that you can work better and help the people who need help and know the secrets of the world where everything is known'. I thumbed through the leaves of the Book, many and many written pages, and alas I thought I did not know how to read... And suddenly I realized I was reading, and understanding all that was written on [*sic*] the Book, and it was as though I had become richer, wiser, and in a moment I learned millions of things.

These quotations lead us to a major aspect of the mushroom *velada*, both in Mesoamerica and Siberia. Almost all the accounts published so far have been written by witnesses new to the experience, whether they ingested the mushrooms or watched those who did. Aristeo Matías told us that the novel effects on the initiate are overwhelming, sometimes terrifying. Nausea is the least of these distressing effects. Double vision has often been noted, and the non-participating stranger is apt to mistake the external symptoms for a drunken stagger. Voices come in sequence from near and far, from all directions. Aristeo warns the beginner that he may see 'visions of hell'. Most of those of our White race who have entered the magic world of the mushrooms are still in the beginners' class: they little suspect what they have yet to learn.

There is no 'catechism' class in the religion of the sacred mushroom. Children seem always to be present at the *velada*. I am astonished, as I look over my slides, to see how children, small and big, are present during the *velada*. María Apolonia carried an infant in her *rebozo* (shawl) throughout the *velada* that she and her mother sang on the night of 13-14 July 1958: the sleeping babe, close held against its mother's body, must have *felt* her singing throughout. In my photos tots are there, and small children also, their faces filled with wonder as they stay close to María Sabina. They do not take the mushroom but go to sleep with the chanting in their ears.

We know that the performance of the *voladores* in pre-Conquest times (as well as now where it still survives) was steeped in religious feeling. The performers would swing down and around a pole some sixty feet high. The head of this troop would stand on a tiny platform on top of the pole and there he would perform a dance to music. Here we find precisely what I think an accomplished shaman, under the influence of the mushrooms, would aspire to do. We know that the ball game of the Mesoamericans was played by youths under powerful religious influence: was their skill enhanced by taking mushrooms? There seems reason to think that the now famous 'mushroom stones' were in some way connected with the ball court, and this then would be the link.

(*Infra* pp 195 *ff*) We know the glow of religious feeling that follows the ingestion of the entheogens. We know how marvelously disciplined the mushroom adept becomes. The ball court player, the *volador* performer, were both saturated with religious feeling. The Conquest of course put an end to the public use of the entheogens and the informants of the friars were often tongue-tied where these plants played a rôle. I do not say mushrooms were used in these events. But the possibilities of the entheogens in these situations make inevitable the question, and I think the mushrooms may well have been so used.

Wherever they are known among the Indians the sacred mushrooms inspire awe and wonder. They are *muy delicados*, a word semantically akin to 'dangerous', and the mushrooms call for utmost care in handling. The mushroom *es habla*, is the Word.

Se ve todo, se ve donde Dios está también: 'You see everything, you see where God is also'. Among the Mixe and as we have seen among the Mazatecs, and undoubtedly among other Mesoamerican people, the sacred mushroom *nace por sí mismo*, 'is born of itself'. In San Juan Mazatlán of the Mixería, after the mushrooms are gathered, they are taken straight in a covered *jícara* (gourd) to the village church, where there is no incumbent, only a local *sacristán* (sexton) who has the keys, and with a lighted candle of virgin beeswax they are left on the altar until they are used. In the Nahuatl country of Veracruz, Rufina de Jesus told us the story of a young man who said he was taking the mushrooms to Mass before ingesting them. I report only the instances that I have witnessed: there must be hundreds of village churches where similar practices are customary. In Huautla, María Sabina, though her calling is universally known, has been a church member in the best of standing all her life. The mushrooms have come full circle since the friars stormed against them in the sixteenth century: the fury of Motolinía and his colleagues against them could scarce find words to express itself. Today, in the Indian villages, the mushrooms share the same altar with the Host.

Work to be done

On 13 May 1957 we published our account of María Sabina's mushroom *velada* in *Life* and, expanded, in *Mushrooms Russia & History*. Later the *Life* article appeared in Spanish and yet later Roger Heim and I told the story once more in *Les Champignons hallucinogènes du Mexique*. These brought favorable reviews not only in the lay press but in scholarly journals, and they drew world wide attention. In the outside world untold thousands down the years have ingested the sacred mushrooms or psilocybin their active agent. Mycologists, chemists, pharmacologists, and psychiatrists have worked on and with them. There have been a number of valuable contributions to our own work:

a. Fernando Benítez, professional writer, in Vol. 3 of *Los Indios de México*, devoted a long essay to María Sabina, accurate and rich in fresh insights; also in *Los Hongos Alucinantes* published in 1974 in the Bibliografía Era;
b. Alberto Ongaro, an Italian journalist with *L'Europeo*, came expressly from Milan to Huautla de Jiménez to interview María Sabina, to whom through an interpreter he put a number of cogent questions: her answers of high value carry the ring of poetic and dramatic truth;
c. Alvaro Estrada, a Mazatec who has taken down from her mouth and translated into Spanish, in simple words catching the very flavor of her Mazatec tongue, the story of her life and her conception of the sacred 'little things';
d. Henry Munn from whose unpublished manuscript with his generous permission I have already quoted;
e. I recorded on tape the entire *velada* sung by María Sabina on the night of 12-13 July 1958; it was translated by the Mazatec specialists George and Florence Cowan; the Mazatec text, and the Spanish and English translations, in three parallel columns, were printed in full, the music transcribed by Willard Rhodes the renowned ethnomusicologist, the photographs of the *velada* by Allan Richardson illustrating the text; with every aspect of the performance duly commented on by us and by Robert J. Weitlaner. Harcourt Brace Jovanovich Inc published the production, with either tapes or recordings, in 1974.

Alberto Ongaro and Fernando Benítez showed what first class writers can do in treating shamanism, but as journalists theirs were one-shot affairs and we can hardly expect anything further from them.

After the reviews no word has reached me of any further response from academia, *ie* anthropologists, archæologists, linguists, Mesoamerican historians, faculties of religion.

In recent decades shamanism has evoked much discussion from academic circles and far beyond. Yet our knowledge of shamanism has suffered from a vital, a fatal defect: the absence of familiarity with the provenience of the singing and with the content of the verses in the remote tongues that the singers use. Moreover, the difficulties do not stop there: in the liturgical verses of the shaman there often occur obsolete or obsolescent turns of phrase that the shaman himself may be at a loss to understand. The help of the elders in the community is needed in trying to render them. In the Mazatec world with Estrada's and Muon's help there is more than a possibility that we shall soon have unprecedented access to the full meaning of the Mazatec singers' chants. Strangely, the response in the universities to our 1974 publication dealing with the heart of shamanism, itself a product of sixteen years of labor by a team of recognized specialists, has apparently been zero. It was a windfall that Alvaro Estrada, himself a Mazatec, should have offered to us on his own initiative a book on María Sabina, and a double windfall that it should be as perfect as it is, capturing in Spanish her way of speaking and thinking, without a trace of vulgarization. Henry Munn's approach is different but no less valid, as we have seen in his paragraph of lyrical prose that I have quoted, and these two men, close friends, constitute an admirable team to do serious work in the Mazatec area.

There is left a whole world of field studies crying to be done before rapidly developing mankind blots out the Old Order, field studies not primarily in the mycological and chemical fields, where Professor Heim and Dr Hofmann and their teams have arrived at the major discoveries, but in the linguistic area and the world of the Indian mind. We know virtually nothing about the mushroom vocabulary in the languages of the highland Maya: this is a big desideratum. Here is an area to be explored until we arrive at the answers as well as we now know the Mazatec. The same holds true with the seven mutually unintelligible Zapotec dialects: a good anthropologist with a passion for linguistics should master this complex, bring back tape recordings of shamanic sessions, take charge of translating them into Spanish and perhaps English as well, and compare the usages with the Mazatec. We know nothing about the rôle of mushrooms among the Otomi, who played an important part in pre-Conquest times, little about the Totonacs, nothing about the Tarascans. These peoples all once used the mushrooms and perhaps they all do to this day. And how about the Zoque? As the mushrooms are sacred and hedged about with profound tabus, no novices in linguistics and anthropology should enter this field: they only muddy the waters. What is needed are accomplished scholars, young, hardy, dedicated, who are capable of a sympathetic approach to religious beliefs that they cannot share.

Siberian and eurasian parallels

As we have seen, the Sacred Mushroom complex of Mesoamerica seems to be linked with the Siberian, suggesting forcibly, perhaps ineluctably, that they have a common origin.

a. Throughout Mesoamerica the Sacred Mushrooms evoke an imaginary world of little people, girls and boys, more or less the size of mushrooms, given to pranks when not engaged in their serious business. They are the spirits of the mushrooms. The same holds true in Siberia.
b. The mushroom speaks through the voice of the shaman in Mesoamerica and also in Siberia.
c. In several of the Uralic languages a person inebriated on mushrooms is said to be 'bemushroomed': the tribes speaking those languages before the arrival of the Russians seem to have not known alcoholic inebriation. (In this they are like most North American Indians and Eskimos before the White Man arrived.) In Nahuatl, though the Nahua made fermented drinks from of old, they also have had recourse to a similar word for mushroom inebriation:

   > In mopoanj, in atlamatink in cuecuenotl: ipan mjtoa *monanacavia*.
   > Of one who is haughty, presumptuous, vain, of him it is said: 'he is bemushroomed'.
   > [*Flor. Codex*, Dibble & Anderson, Bk 11 'Earthly Things', p 132]

   Unfortunately we do not know whether the Paleosiberian tribes - Ket, Yukagir, Gilyak, Chukchi, *etc* - using the mushroom made a verb of it. If Russian linguists have explored this area in the languages of those peoples, their findings have not reached me.
d. In Nahuatl there is linguistic evidence for the special status of entheogenic mushrooms in the very grammar of the language. This corresponds to our similar discoveries in the Santal languages spoken by

a tribe in India and in the languages of the East Slavic group - Russian, Belorussian, and Ukrainian. The unique status of mushrooms in Nahuatl must carry us back far indeed, perhaps to the migrations from Siberia. It speaks for the religious awe felt for the Sacred Mushroom among these peoples far removed from each other.

e. In Mesoamerica we have developed and published evidence that the music of the chants sung in the *velada*, and also many of the verses, are of ancient indigenous origin, and that evidence is further supported (as we shall see) by the murals of Teotihuacán. This points to an origin lying deep in prehistory. We need for comparison the recordings of the chants sung in Siberia by the shamans who formerly used the mushrooms.
f. In 1956 in my first paper dealing with ethnomycology I developed evidence that linked mushrooms with the lightning bolt. I will return to this subject in my next book, which will be a sequel to my *SOMA: Divine Mushroom of Immortality*. For the present I will only say that in Mesoamerica the tie that binds the lightning bolt to the hallucinogenic mushrooms is strong: I find it among the Nahua, the Mazatecs, and the Zapotecs. Here is a powerful folk belief that survives in many places in the Northern Hemisphere, in the Old World and the New. It must go back far into prehistory.

We must not forget the slowness of change in proto- and prehistory. There were perhaps, even probably, other plants to which supernal powers were attributed, but the Wondrous Mushroom seems to have enlisted virtually universal adoration in the Northern Hemisphere. This mushroom may have been a *Psilocybe*, or the *pongo* (*Amanita muscaria*) of the Siberians, the *miskwedo* of the Algonkians, or a *Claviceps*, or yet others still unknown to us. Here was the Secret of Secrets of the Ancients, of our own remote forebears, a Secret discovered perhaps sporadically in Eurasia and again later in Mesoamerica. The Secret was a powerful motive force in the religion of the earliest times. By refraction and reflection the Secret crops out in fossil meanings, fossil sayings, fossilized folkloric bits of our various languages.

One question confronts us: our folkloric world, appealing nowadays chiefly to children, of fairies, elves, gnomes, of Queen Mab and the goblins, of leprechauns and trolls, of *duendes* and *trasgos* in the Spanish world, etc, are they descended directly from the world to which the Wondrous Mushroom introduced our remote forebears, the Little People, sometimes endearing, sometimes infuriating, of a Magical Eden?

The Past

CHAPTER 3

Xochipilli, 'Prince of *Flowers*': a new interpretation

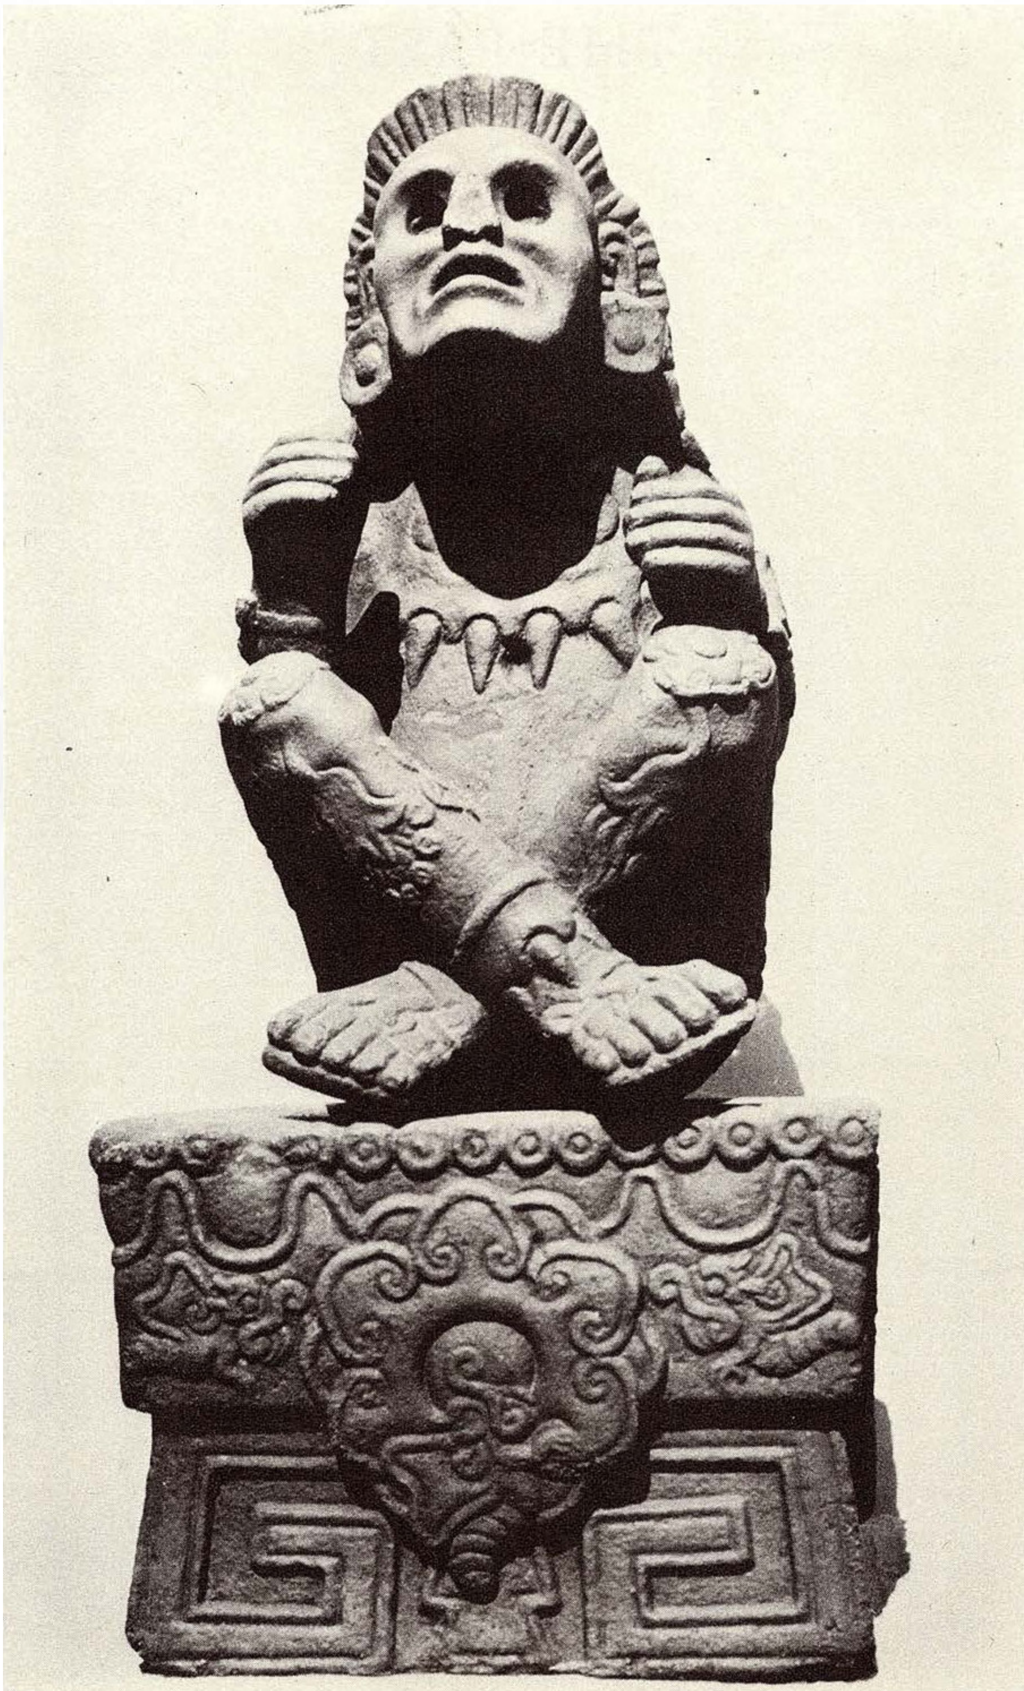

Fig 1 Fullface view of Xochipilli

In the Museo Nacional de Antropología of Mexico there stands a remarkable piece of statuary known as Xochipilli, the 'Prince of Flowers'. So far as I know, only in Mesoamerica does the pantheon of Early Man include a divinity dedicated exclusively to 'flowers'. 'Xochi-' is from Nahuatl *xochitl*, 'flower'; '*pilli*' means either 'Prince' or 'child', and parallels our former use in English of 'child' as a high-born youth (*eg* Byron's *Childe Harold*), and also the use of *Infante* in Spanish. No one disputes the meaning of Xochipilli. But do the 'flowers' of which Xochipilli is Prince mean flowers?

The statue and what we call its base were unearthed at Tlalmanalco on the approaches to the volcano Popocatepetl in the middle of the last century. The 'base' in reality is an integral part of the statuary, being a reproduction in miniature of the lower part of an Aztec temple on which Xochipilli, life-size, is seated.[15] On the strength of stylistic features it is believed that the statue was carved a generation or so before the arrival of the Spaniards.

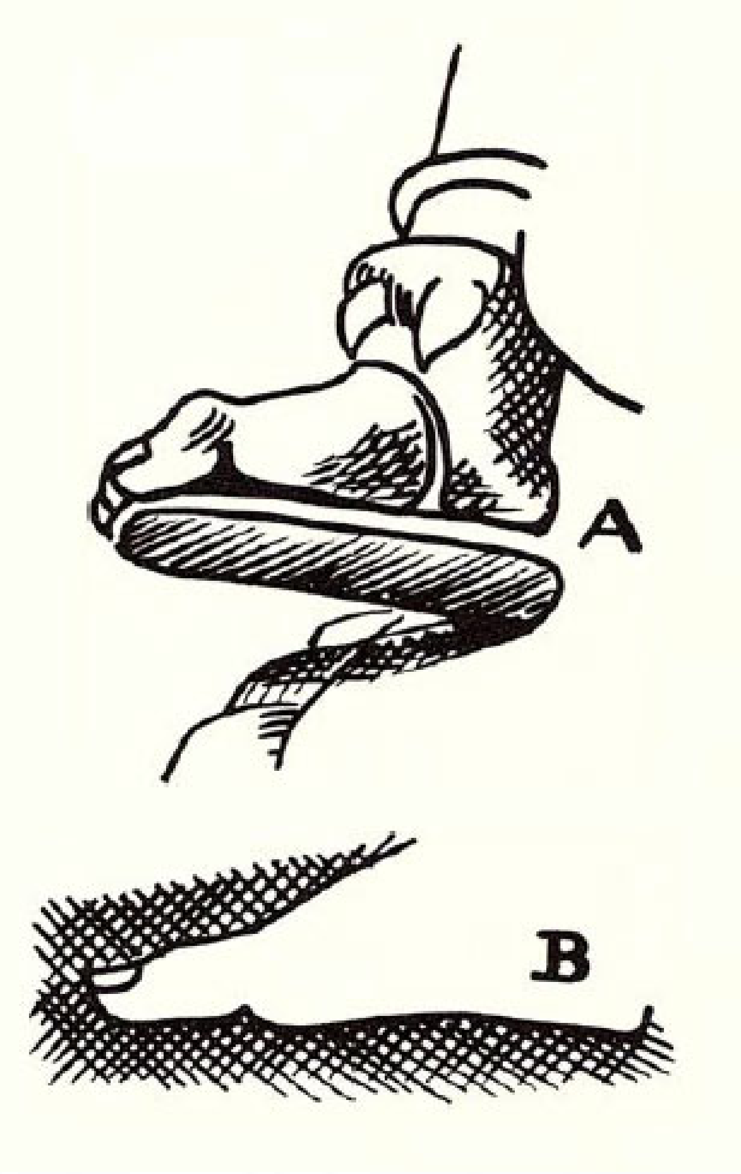

Fig 2 a) Retracted big toe of Xochipilli;
b) normal foot

---

[15] One side of the base differs in design from the other three, bearing two butterflies where the others carry *tonallo* glyphs. (See p 64) Over the decades the side with butterflies has sometimes faced forward and sometimes backward, the fit of the statue in its 'base' being perfect either way. In our Figure 1 showing the front view of Xochipilli, butterflies flank each side of the mushrooms. Since that photo was taken, the 'base' has been reversed and now displays the *tonallo* insignia, as seen in the Nicholson photos. The 'base' is carved to represent the *talud* and *tablero*, the 'batter' and 'entablature', of the typical Mesoamerican temple.

The overall expression of this Prince of Flowers is breathtaking. The skyward tilt of the head and eyes, tense half-open mouth, jutting jaw, hands poised at different levels, crossed legs with feet almost wholly off the ground, the strain expressed by the retraction of the right big toe - they are all of a piece. (Margaret Seeler, who has done almost all my black-and-white drawings, went expressly to Mexico City to study the statue of Xochipilli. It was she who discovered the retracted big toe: the pre-Conquest sculptor spoke alone to her, the artist, across a chasm of half a millennium.) They are far from conveying the quiet joy of a flower buff. The eyes then would be turned earthwards and a feeling of repose should suffuse the whole figure.

One key to the enigma of this figure lies in the mask that the man is wearing. It can be seen in the eye-sockets and better still under the chin. (Fig 3) In the cultures of the West masks are no longer important: they are relegated to children or to light-hearted merry-making as in masked balls and frivolous festivities that welcome in the New Year. But in antiquity and virtually all the other cultures of the world the mask takes on grave import. It shows the salient trait of character that the wearer portrays, being the personification of that trait. In our statue the mask portrays a god living in ecstasy and does so with the power of genius. Here is one who is not seeing, not living as ordinary mortals see and live, who is seeing direct with the eyes of the soul. This being is not with us, is in a far-off world. He is absorbed by *temicxoch*, 'dream flowers' as the Nahua say describing the awesome experience that follows the ingestion of an entheogen. I can think of nothing like it in the long and rich history of European art: Xochipilli absorbed in *temicxoch*.

The late Justino Fernández has given us a detailed description and explanation of this statue in 'Una Aproximación a Xochipilli' in Vol I of *Estudios de Cultura Nahuatl*. His study is a first class professional dissection of the statue following conventional standards of the past. I have learned much from it, as anyone familiar with it will discover from my text, but I disagree with his overall interpretation. It becomes clear that Fernández had never enjoyed the experience of the entheogens, had never even given the rôle of entheogens in Mesoamerican culture serious thought.

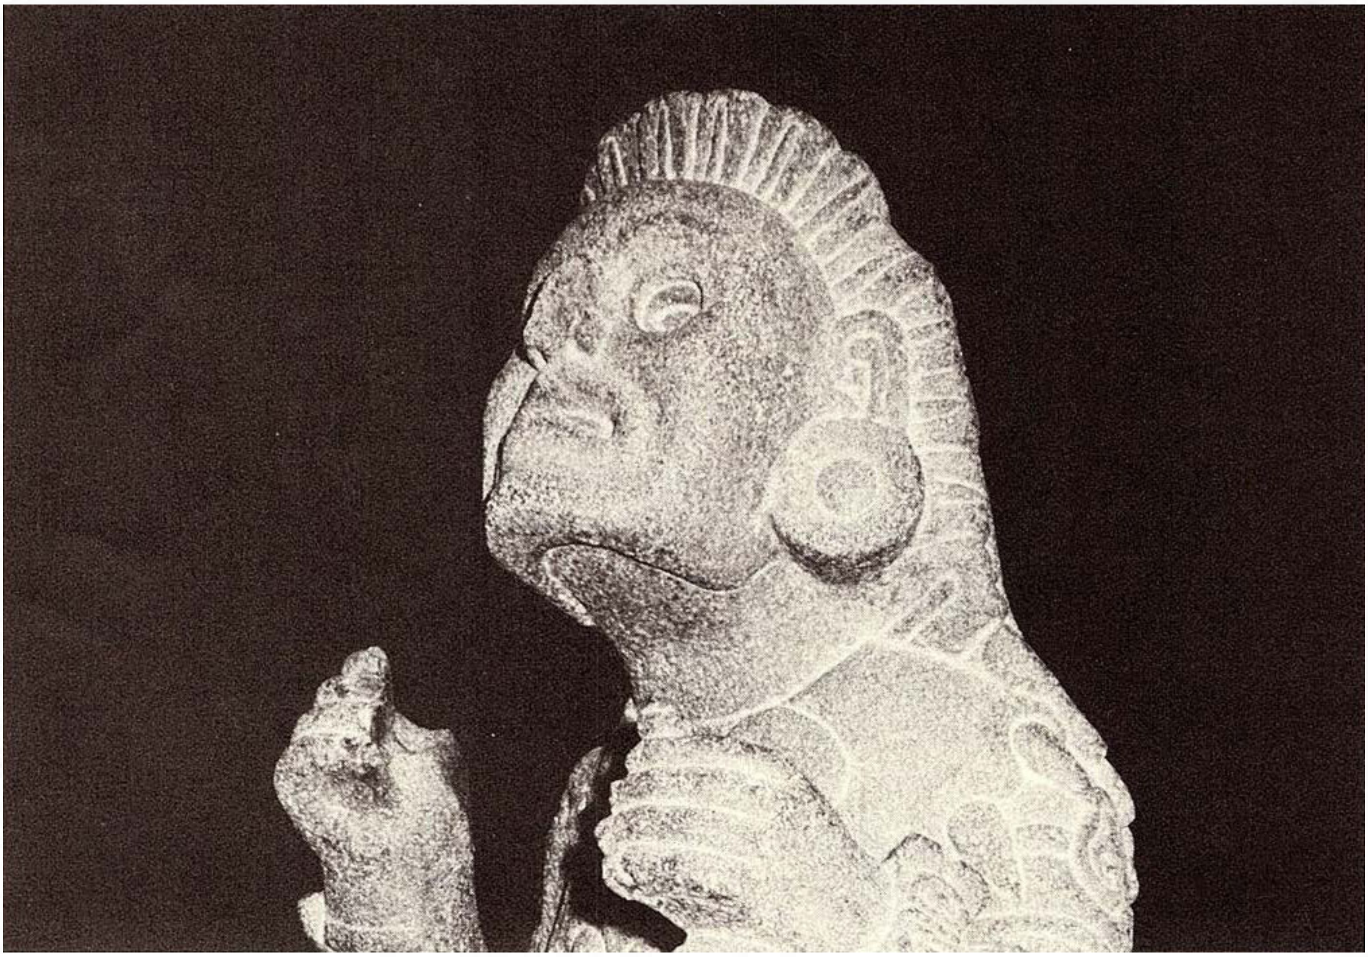

Fig 3 Detail of Xochipilli showing mask

Fernández could not help seeing the 'ecstasy' (this is *his* word) in the expression on the man's face, but for his explanation ecstasy is superfluous, even out of place, and he would minimize the trance-like pose for the viewers by suggesting that if the eye-sockets were filled with turquoises or other gems, as he is compelled to think they once were, this impression would be reduced or even eliminated. For me it would be surprising if gems had ever filled the eye-sockets. The figure indeed wears a mask, but in this style of mask the sockets are normally empty to allow the wearer to see.

The ecstasy in this figure is of the essence. Here is the work of a master, a supreme carving of a man in the midst of an unearthly experience, the formal hieratic effigy of the God of Rapture, the God of 'Flowers' (as the Aztecs put it): the god of youth, of light, of the dance and music and games, of poetry and art; the Child God, the god of the rising sun, of summer and warmth, of flowers and butterflies, of the 'Tree-in-*Flower*' (*Xochicuahuitl* or *Arbol Florido*) that the Nahuatl poets frequently invoke, of the inebriating mushrooms (*las Flores que embriagan*), the miraculous plants that transport one to a heavenly Paradise.

The exposed parts of the body as well as the 'base' are covered with carvings of flowers. Strange that no one, from Seier and Gamio to Justino Fernández, no archæologist, no botanist, no art historian, has stopped to identify them! The carved flowers are the unique feature of this statue, but no scholar, no scientist, has entered into this unique feature! From earliest times Mexico has abounded in excellent botanists, Spanish and Mexican and later from the whole world. (An imperative though unconscious inhibition seems to grip scholars when their natural instincts would lead them into the Paradise - the *Tlalocan* - of the entheogens.) Those flowers carved on the body of Xochipilli hold the key to the meaning of the statue and moreover to the metaphorical meaning of 'flowers' in Nahuatl and Mesoamerican culture.

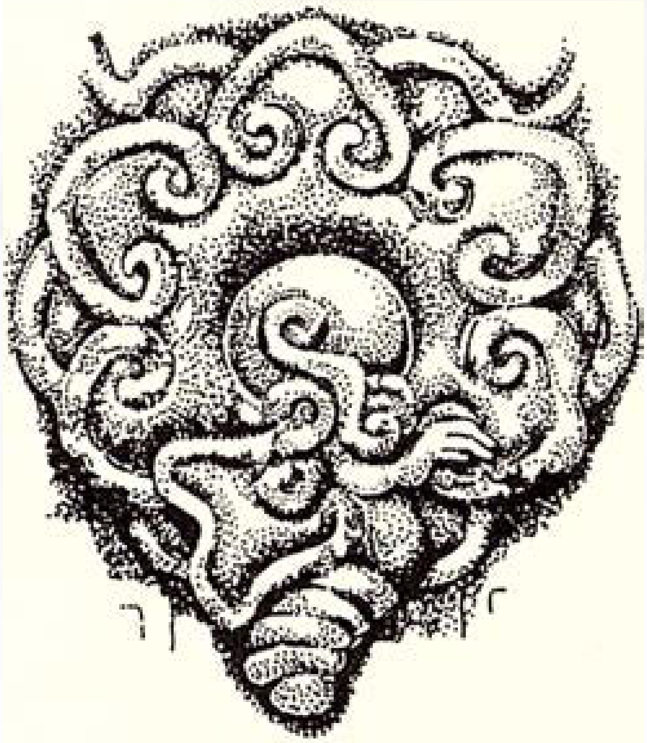

Fig 4 Mushroom emblem on base of statue

Since I first fixed my gaze on this statue of Xochipilli in the late 1950's, the emblem adorning all four sides of the base, obviously a plant motif, caught my attention. (Fig 4) Many have referred to it as a 'flower', but what flower? From the beginning I felt the five convex devices with inturned margins arranged in a circle were mushrooms. They represent the mushrooms in profile. A sixth is hidden by the carving of a mythic butterfly. The caps of mushrooms offer us an infinite variety of shapes, in the wide variety of species and the different stages of the life cycle of each species.

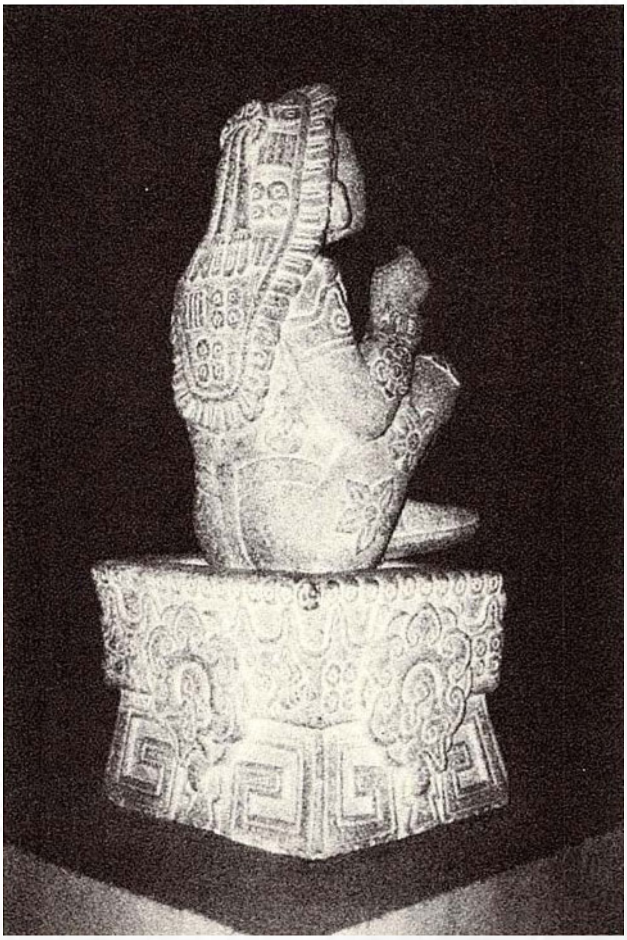

Figure 5

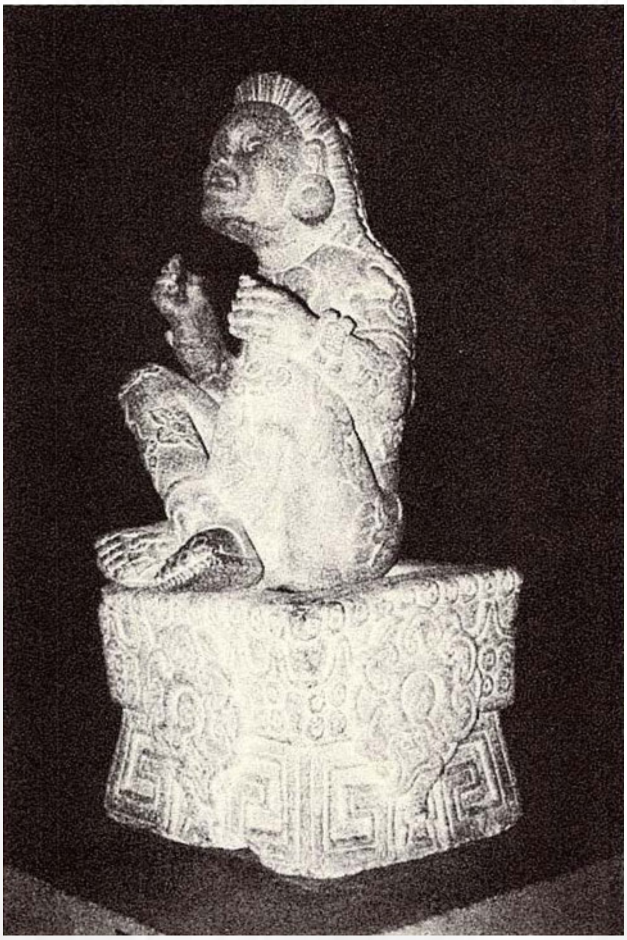

Figure 6

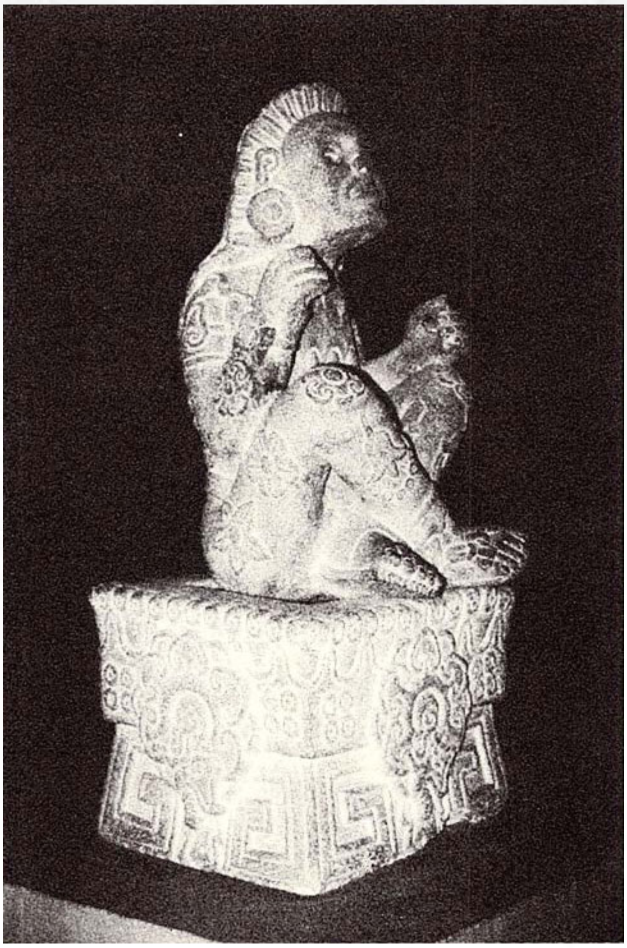

Figure 7

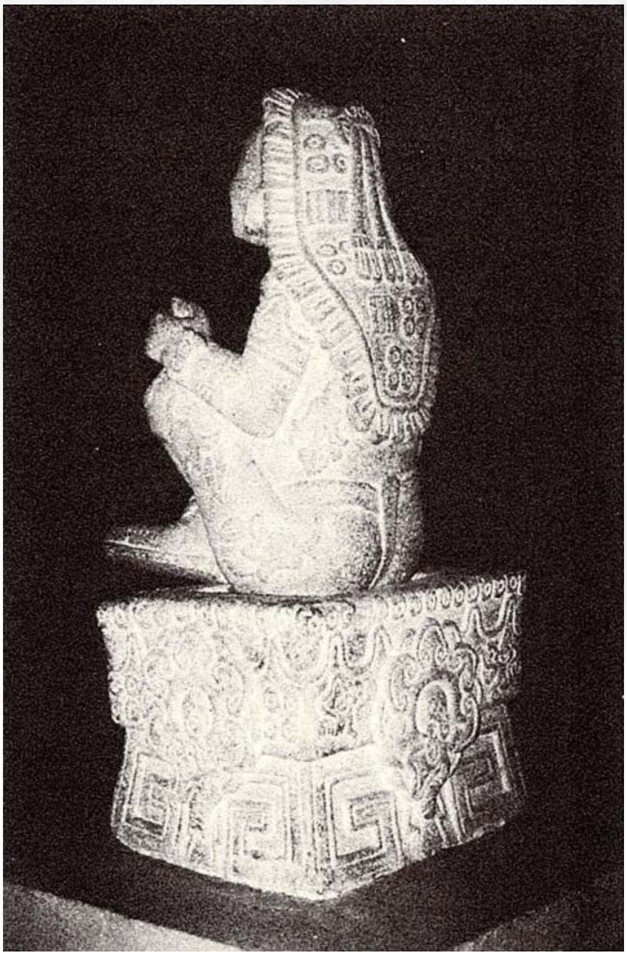

Figure 8

Even among the entheogenic species of Psilocybe, Stropharia, and Conocybe there is endless diversity. Let us remember that the statue comes from the slopes of Popocatepetl. In the beliefs of the Mesoamericans, Paradise - their *Tlalocan* - was situated on the slopes of a verdant mountain to the East and for the Aztecs the towering massif topped by the volcano Popocatepetl was their *Tlalocan*, their Garden of Eden. Here is where our statue was found, in the heart of the sacred mushroom country. Here in this precise vicinity was where Professor Roger Heim discovered, thanks to the indispensable help of descendants of Nahua Indians, *Psilocybe aztecorum* Heim, a species then new to science, illustrated in color in *Les Champignons hallucinogènes du Mexique*,[16] Plate XV, with the description on pp 154-158. His figures 15 and 16 of specimens found in their natural habitat show the cap (or 'pileus') at the moment when it breaks forth into maturity. The mushrooms in the refractory stone medium catch admirably the precise convex shape of the actual pileus of the living plant. Henry B. Nicholson in his photograph (Fig 15) brings out not only the profile that had caught my eye: his lens gives body to the stipe and flesh of the cap. The inturned margins (*la marge... incurvée*, as Professor Heim says) are one of the specific characteristics distinguishing this species of *Psilocybe*. The left-hand Fig. 9a reproduces what we find on the statue and the right-hand Fig 9b the illustration in *Les Champignons hallucinogènes du Mexique*:

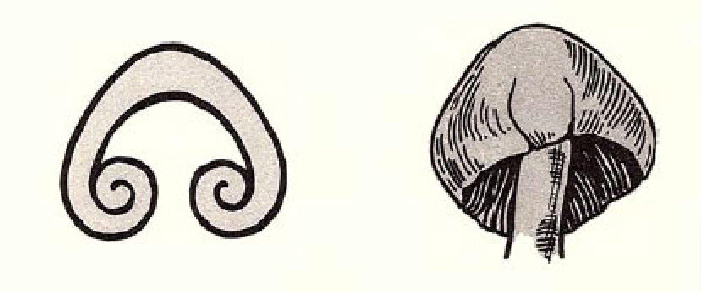

Fig 9 Profile of a) design on 'base' of Xochipilli and b) *Psilocybe aztecorum*

Mushrooms also appear on the body of our man in rapture - on both his knees, on his right forearm, on the top of his head. (Fig 13) There are three in each case, instead of six, and just as on the *tablero* we see the caps of another row of mushrooms behind and between the mushrooms in the foreground. But on the body the carving is not done with such care. We cannot hazard a specific designation as we did for the one in Fig 9a. I think the mushroom designs on the body of Xochipilli express rather a glyph for any of the many species of entheogenic mushrooms, a glyph that we might expect to find elsewhere. (Fig 10)

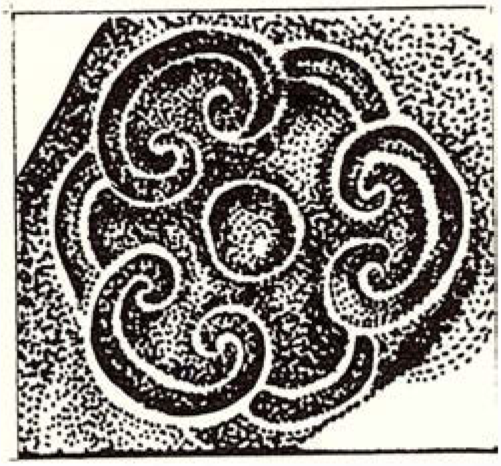

Fig 10 Glyph of the mushrooms

On the base of our Xochipilli we find what everyone familiar with Mesoamerican art will recognize as a highly stylized butterfly, perched among the mushrooms and concealing the sixth one, apparently feeding on them. Why the butterfly? In our world of nature mushrooms seldom or never draw butterflies, but in Mesoamerican iconography butterflies play an important mythic rôle, as we see in the butterflies of the famous mural of

---

[16] By Roger Heim, R. G. Wasson, and others, published in 1958 as a *Mémoire* by the Muséum National d'Histoire Naturelle in Paris.

Tepantitla in Teotihuacán, showing us (according to Alfonso Caso) *Tlalocan*, the paradise of the Nahua for certain selected individuals. Butterflies are associated with the land of fortunate departed spirits. They embody the spirits of the dead. George Cowan in *Yan* (1953 No 2) has told us that in some parts of the contemporary Mazatec world butterflies are still considered to be the souls of the departed revisiting their native haunts. On the base of the statue of Xochipilli the butterfly is feasting on *teonanácatl*, which may have been considered the food of the gods, to whose world the mushrooms transport for a brief spell the people of this sad workaday world. Mrs. Seeler has reproduced our mythic butterfly, the symbol that ratifies our identification of the sacred mushrooms.

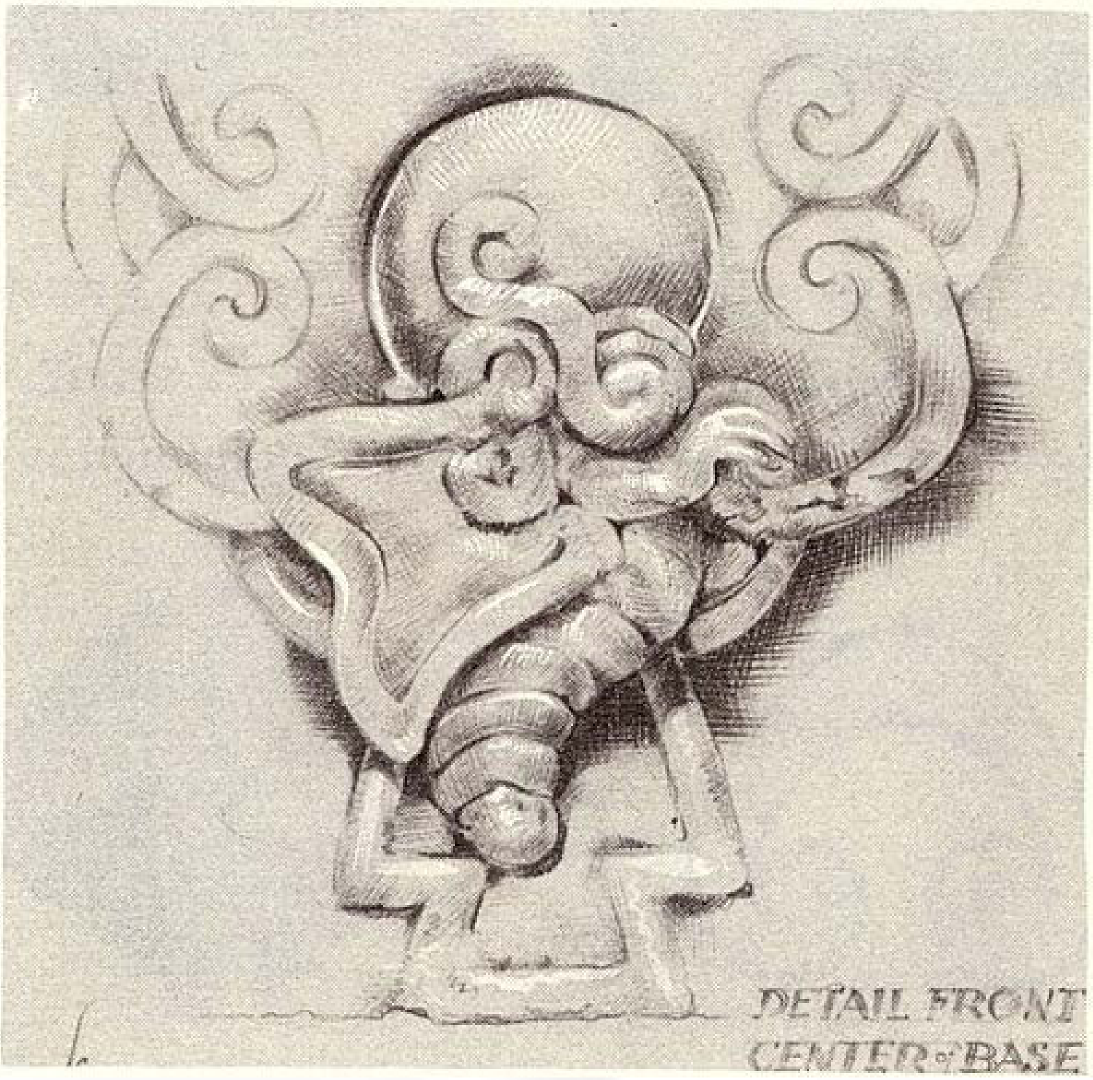

Fig 11 Butterfly on 'base'

There survives a poem from Chalco, close by to Tlalmanalco where our Xochipilli statue was found, and the carving might have been inspired by these lines:

The flowery butterfly passes and repasses.	Xochin papalotl tepanahuia
May it suck honey from our *flowers*	Ma in tlachichina Aya toxochiu
Twisting in and out of our bouquets!	O tomac xochiuh in!

(As we shall see, '*flowers*' in pre-Conquest Nahuatl poetry is a metaphor meaning the entheogens. When so used I italicize it.)

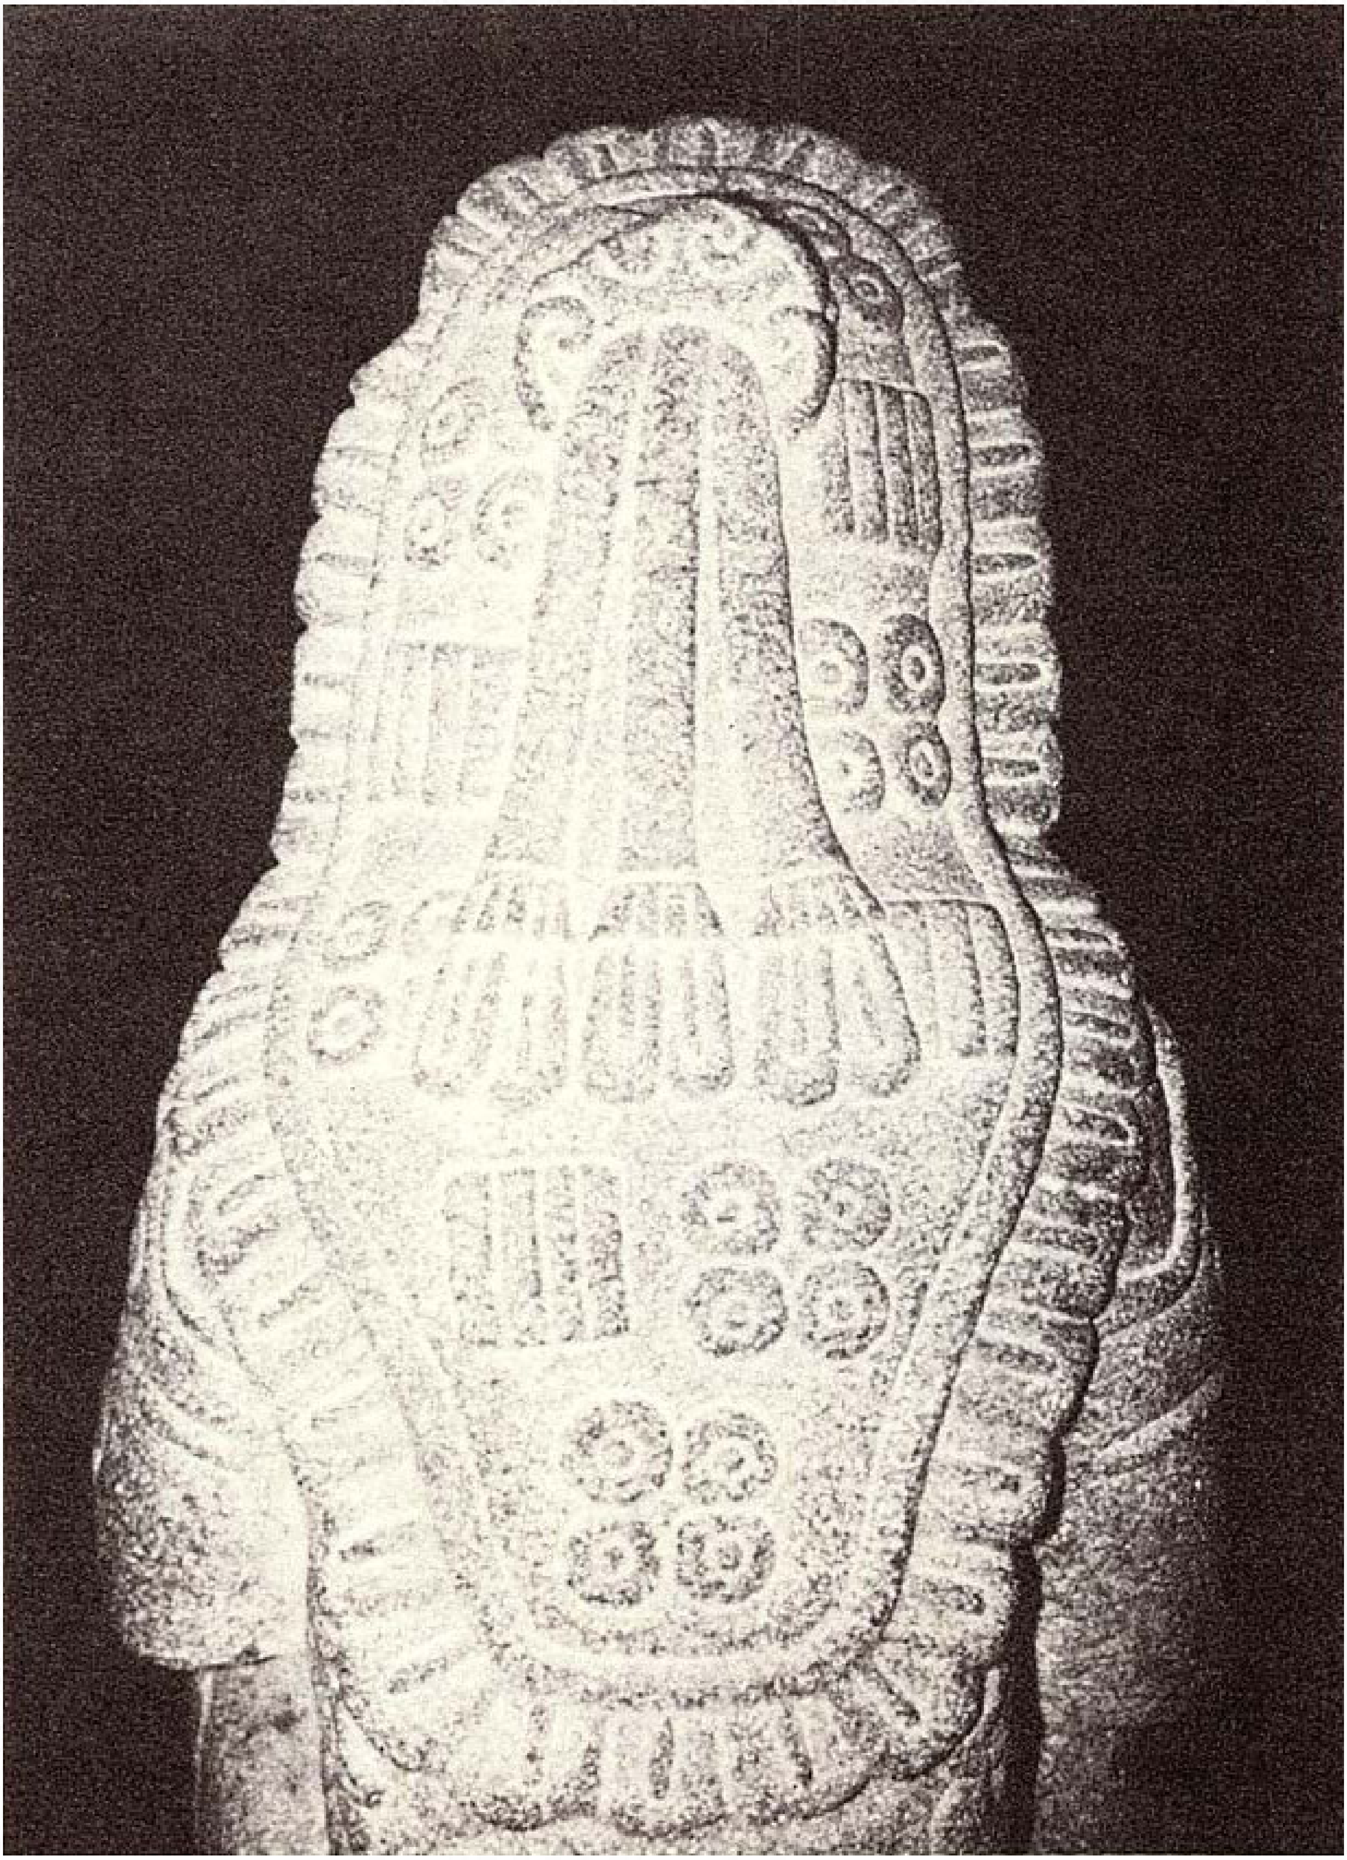

Fig 12 Xochipilli headdress

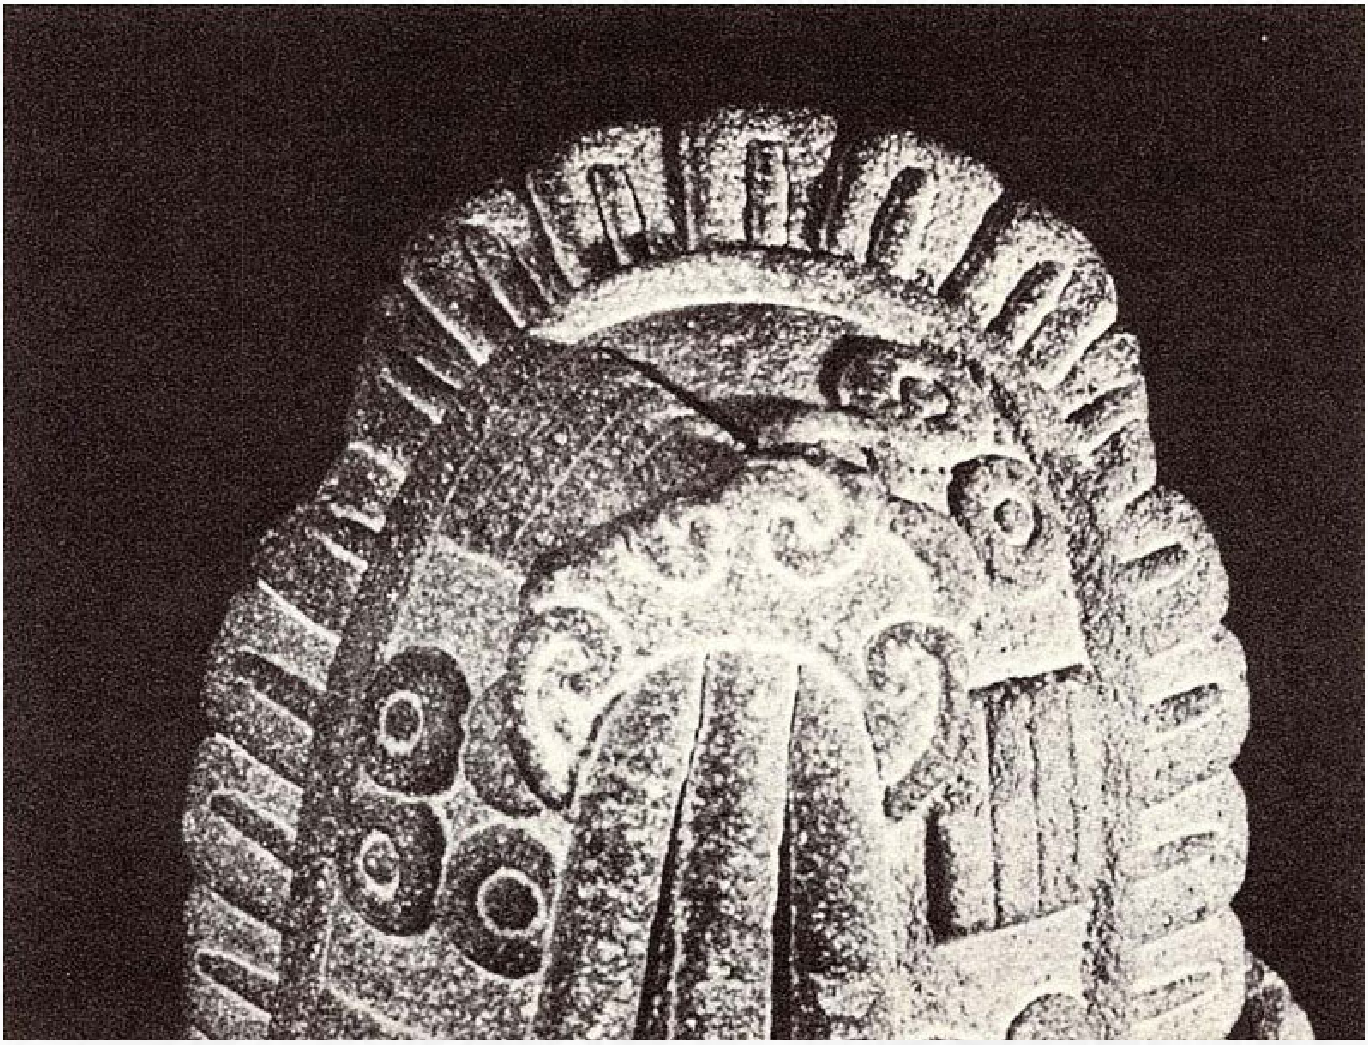

Fig 13 Detail of headdress

On three of the four sides of the base, flanking what are the sacred mushrooms, we find two groups of four concentric circles or balls. Xochipilli's formal headdress (and what a lordly headdress it is, his chief article of apparel!), viewed from behind, carries six such sets of four circles or balls. This is the Nahuatl *tonallo*, the symbol that connotes the summer season, solar warmth, light, butterflies, and *xochitl* (marvelous word!) in its several senses. On his headdress there are no fewer than five balancing symbols - quadrilateral fields divided into four stripes, which probably were once in diverse colors (the whole statue having been painted) - the symbol called *tlapapalli* - a symbol reinforcing the *tonallo* and meaning supreme joy, bliss incomparable. Are not the *tonallo* and *tlapapalli* felicitous for my reading of this statue of Xochipilli as embodying the Aztec esteem for the wondrous entheogen?

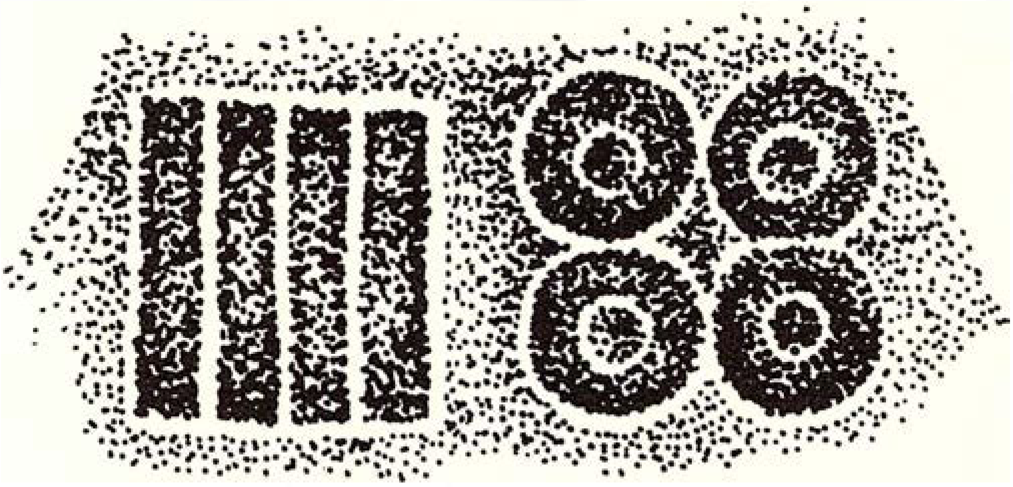

Fig 14 *Tlapapalli* and *Tonallo*

Above the circles of mushrooms on the sides of the 'base' we see a wavy line all around the four sides. Others have suggested that this meant water - a happy suggestion since mushrooms are always associated with showers, rain, moisture, mountain seepage. Along the top rim of the *tablero* there is an endless sequence of concentric circles. These have been called 'solar symbols' and this would not be an incongruous meaning but I will show later (p 170) that they can be differently construed in a way to reinforce my mushroom interpretation.

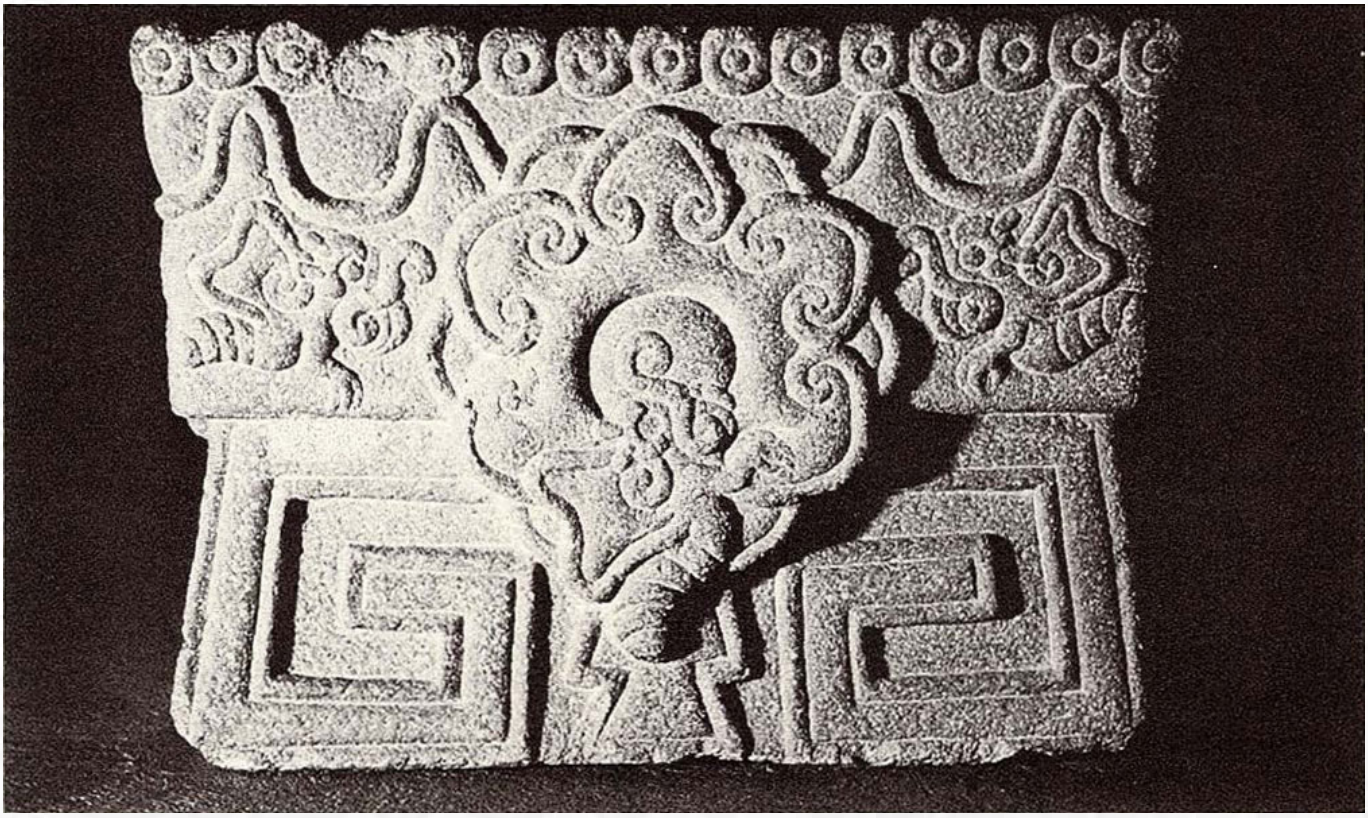

Fig 15 'Base' of statue

Let us now look at the 'flowers' carved on the body of the god. As I am not a botanist, I invoked the help of Richard Evans Schultes, holder of the Paul C. Mangelsdorf chair in Natural Sciences at Harvard and Director of the Botanical Museum there, who with his students, Dr Timothy Plowman and the late Dr Tommie Lockwood, and his colleague the scientific artist Mr Elmer C. Smith, together with me, have come up with the following identifications.

On the statue's right haunch there is a five-petaled carving, the petals being pointed. Schultes and his associates are confident that this is *Nicotiana tabacum*, our common tobacco plant, one of the sacred plants of all Amerindian cultures not only in Meosamerica but throughout the Americas. For four centuries observers of the Amerindians have been telling us that they reverence tobacco as a plant endowed with mystical powers, what we now call an entheogen. Mrs Seeler here reproduces the design on the right haunch, Fig 16a, and also when it is repeated on the left forearm, Fig 16b. Fig 16c is *N. tabacum* as shown in the Britton and Brown *Illustrated Flora*, edited by Henry A. Gleason, Vol 3, p 205.

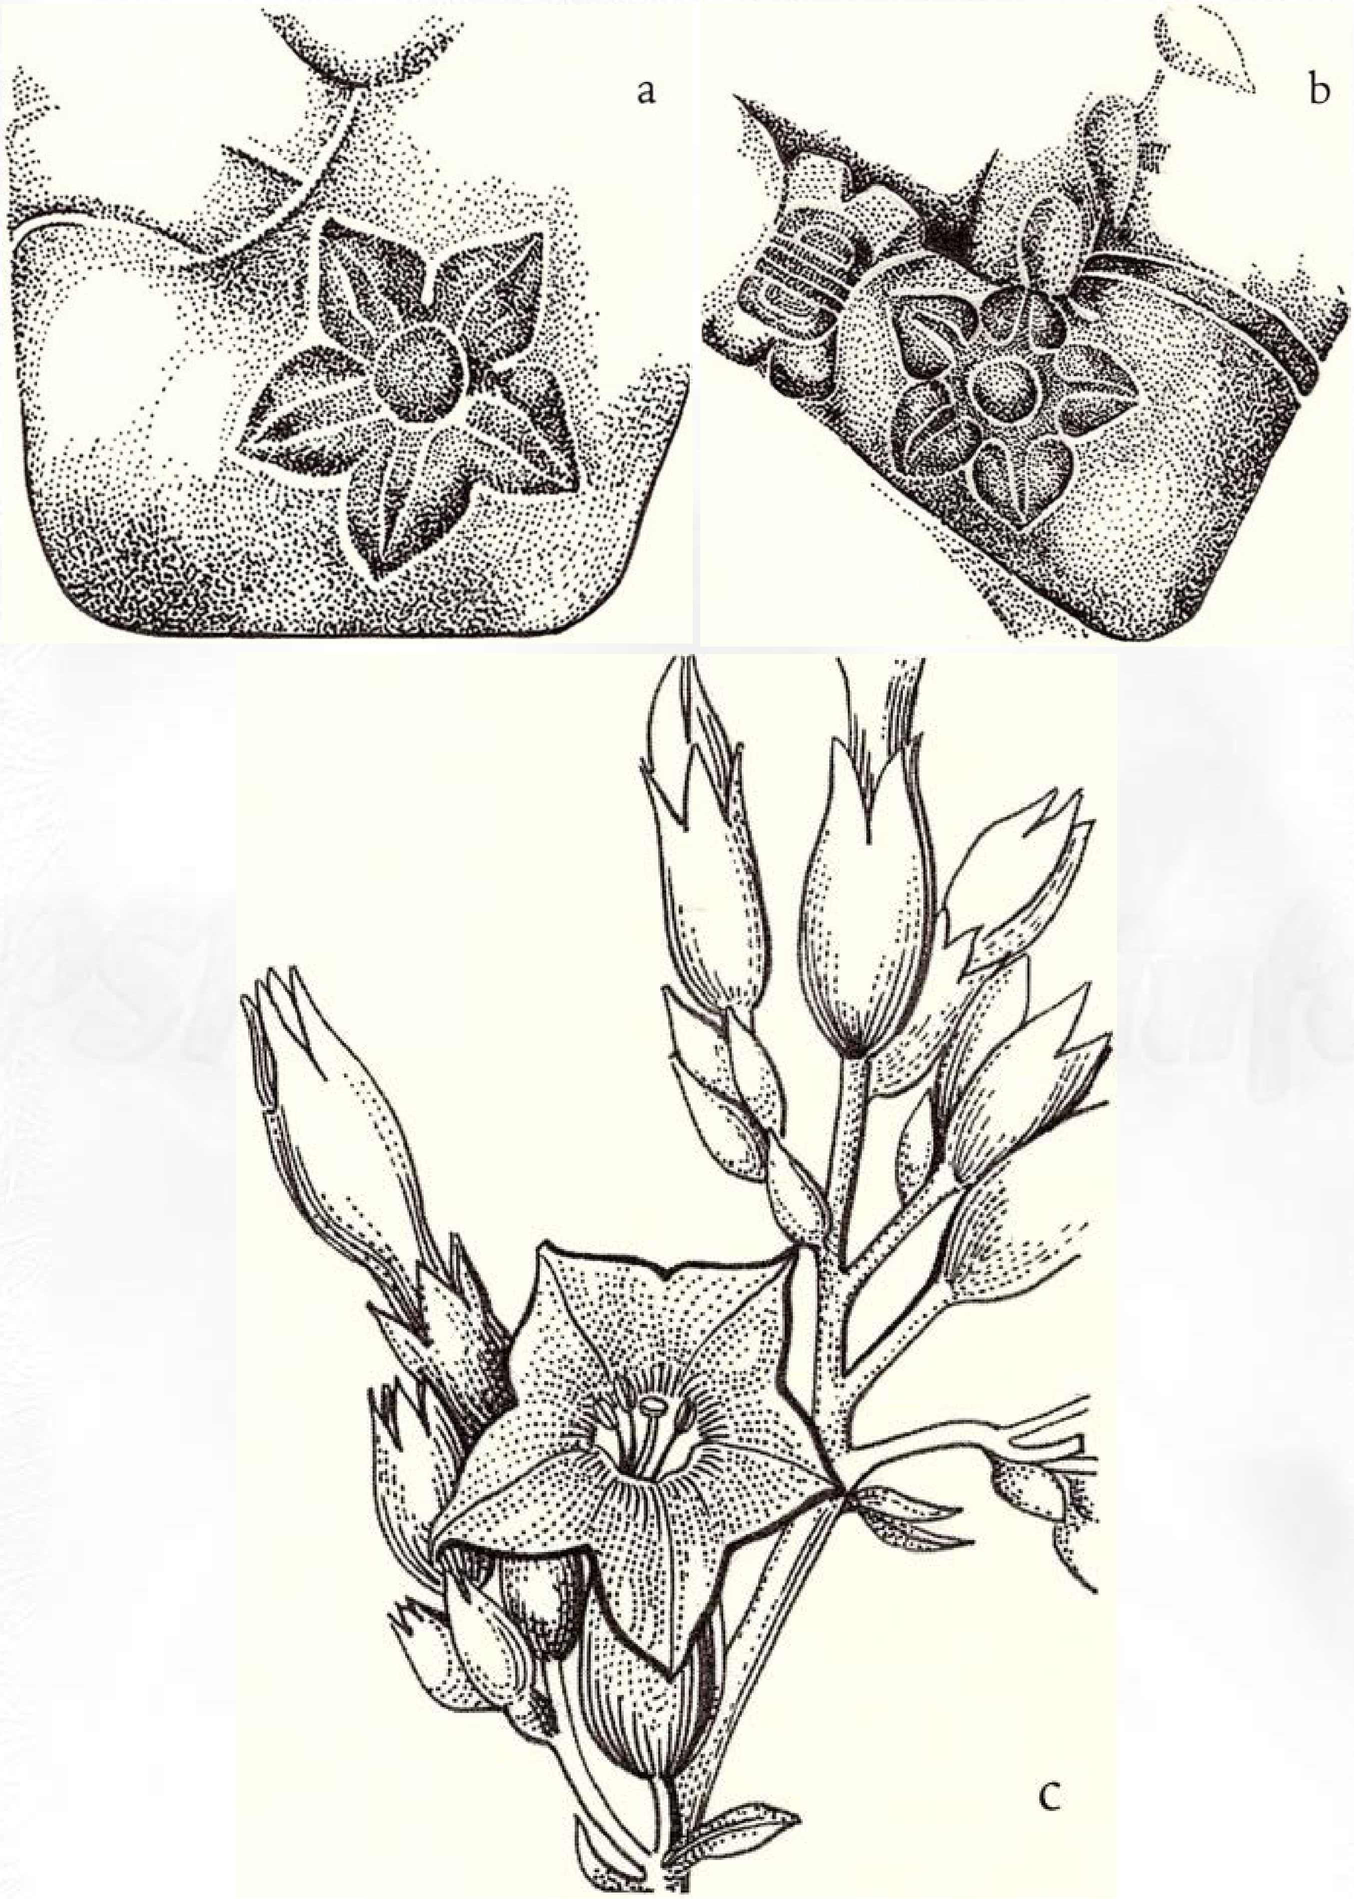

Fig 16 a) Tobacco flower from right haunch of Xochipilli b) Same from left forearm c) Same from drawing of living plant

Let us now turn our attention to *Turbina corymbosa* (L.) Raf., formerly *Rivea corymbosa*, the *ololiuhqui* of the Nahua, the entheogenic morning-glories identified with Mesoamerican cultures. On the right thigh near the knee there is a carving of the morning-glory flower as one views it looking into the cup.[17] Mrs Seeler reproduces the carving on the thigh and also copies the illustration of *Turbina corymbosa* from the same angle as shown in Schultes' classic paper, 'A Contribution to our Knowledge of *Rivea corymbosa*, the Narcotic *Ololiuqui* of the Aztecs', published by the Botanical Museum of Harvard University in 1941. (Fig 17)

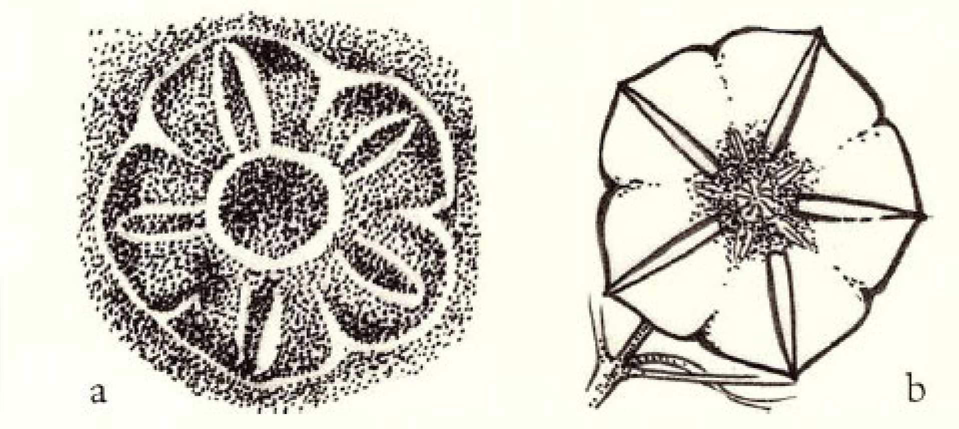

Fig 17 Morning-glory (*Turbina corymbosa*) a) on statue, b) drawn from life

On the left leg below the knee, and again just above the knee on the left thigh, there are, we think, carvings of the emerging morning-glory flower that show the plaiting and convolutions characteristic of that stage in the blossom's life cycle. Fig 18 is Mrs Seeler's design on the left thigh.

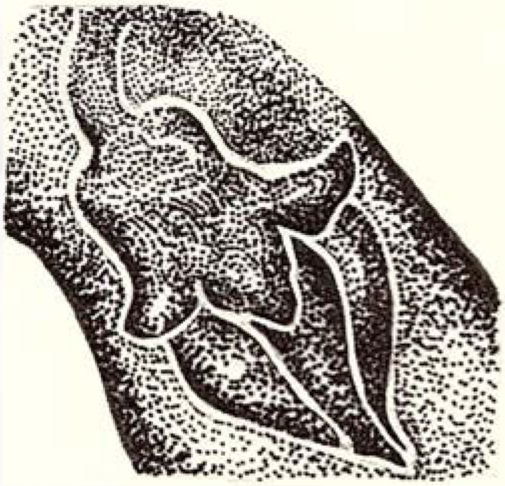

Fig 18 Design on left thigh

So much for *Turbina corymbosa* or *ololiuhqui*.

Schultes is confident that he has identified the flower carved on the right leg below the knee: *Heimia salicifolia*, the *sinicuichi* of the Mexican highlands. Here is Mrs Seeler's comparison of the carving and the actual plant:

---

[17] In *Archeology*, Jan 1973, Vol 26.1, William D. Sturdevant arrived at the same identification of this flower some months before the first version of my chapter appeared in the Harvard *Botanical Museum Leaflets* (Vol 23.8). I gladly point out his priority and would have done so in the *Leaflet* had I known of it. I believe his was the first identification of any flower carved on the Tlalmanalco statue of Xochipilli. But he calls it an 'opiate' which it is not, either botanically or in psychic effect.
One anthropologist insists that this same flower is the *toloache* of Mesoamerica, *Datura inoxia* (= formerly *D. meteloides*). Impossible: the petals of *D. inoxia* are pointed whereas our carvings are rounded, a typical morning glory. *Nicotiana tabacum* and *D. inoxia* are both of the nightshade family, but the carving that we have defined as *N. tabacum* cannot be *toloache*, for the petals of our tobacco carving are acute whereas *D. inoxia* would be attenuate.

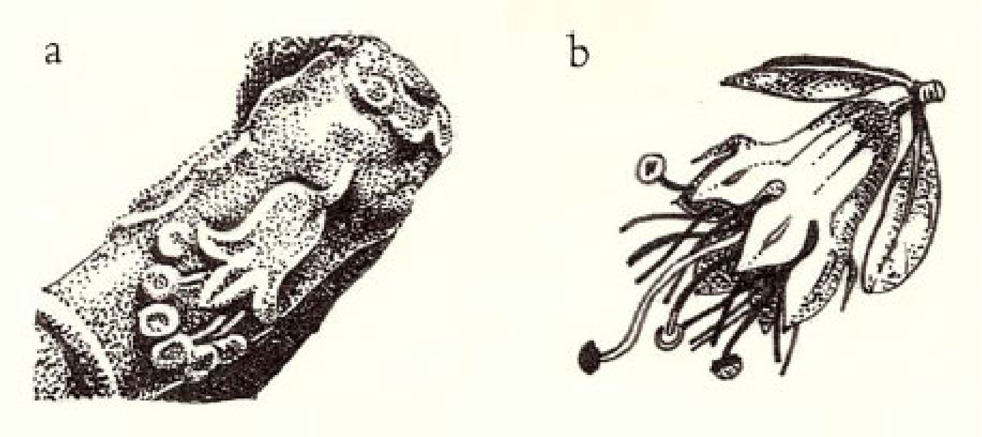

Fig 19 *Heimia salicifolia* a) on statue, b) drawn from life

Schultes says that the plant has 'mildly intoxicating properties', and adds these details:

> Sounds seem to come distorted from a great distance. This plant typifies an hallucinogen of which the hallucinogenic characteristics are auditory, not visual. The natives believe that *sinicuichi* has sacred or supernatural qualities, since they hold that it helps them recall events which took place many years earlier as if they had happened yesterday; others assert that they are able, with *sinicuichi*, to remember pre-natal events.

On contemplating the statue anew one is tempted to see in the tilt of the head and above all in the open mouth that Xochipilli is listening to the far-off voices of *sinicuichi*. Margaret Seeler's drawing is taken from the illustration in the *Bulletin on Narcotics*, Vol XXII, No 1, Jan-March 1970, p 38, in the article by Professor Schultes.

On the left side of our statue, just where buttock and thigh meet, a well delineated flower holds our attention. Schultes, somewhat uncertain, asks whether it could be a swollen bud of *Heimia salicifolia*, just about to open up. As we have seen, *ololiuhqui* (the morning-glory: *Turbina corymbosa*) is probably present on the statue at two stages of its growth: why not *sinicuichi* also? The same flower is carved on the inside of the left calf (Fig 20), and apparently on the right torso. (Here the carving seems unfinished.)

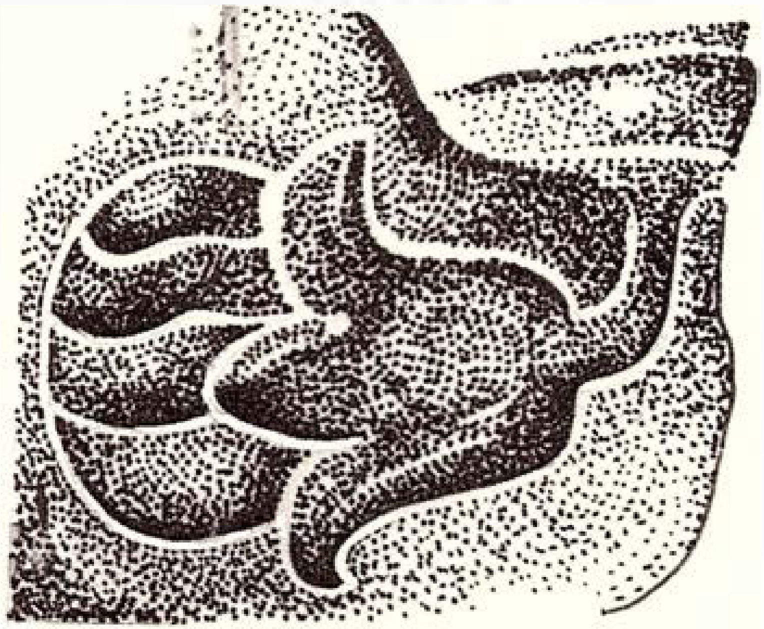

Fig 20 Swollen bud of *Heimia salicifolia* (?)

On the left torso of our Xochipilli, above the belt, there is the carving of an extraordinary flower. When I suggested to Professor Schultes that it might be the flower of the *cacahuaxochitl*, nowadays known to botanists as *Quararibea funebris*, and told him my reasoning, I was delighted that he thought it an excellent possibility, the best so far advanced.

The *cacahuaxochitl* occupied a unique place in the culture of the Nahuatl aristocrats. The pre-Conquest poets speak with almost breathless enthusiasm of it in their verses and also of its flower, the *poyomatli*,[18] which at last we can now link with the tree. The sculptor of the Prince of *Flowers*, having undertaken to carve on Xochipilli's body the *flowers* that figured large in the cultural life of the Nahua, could not sidestep the *poyomatli*. It was a must. The artist, unfamiliar with the flower in its native habitat, did the best he could. Here is Mrs Seeler's drawing of the actual flower, done after the illustration in *Arboles Tropicales de México*, by J. D. Pennington and José Sarukhan:

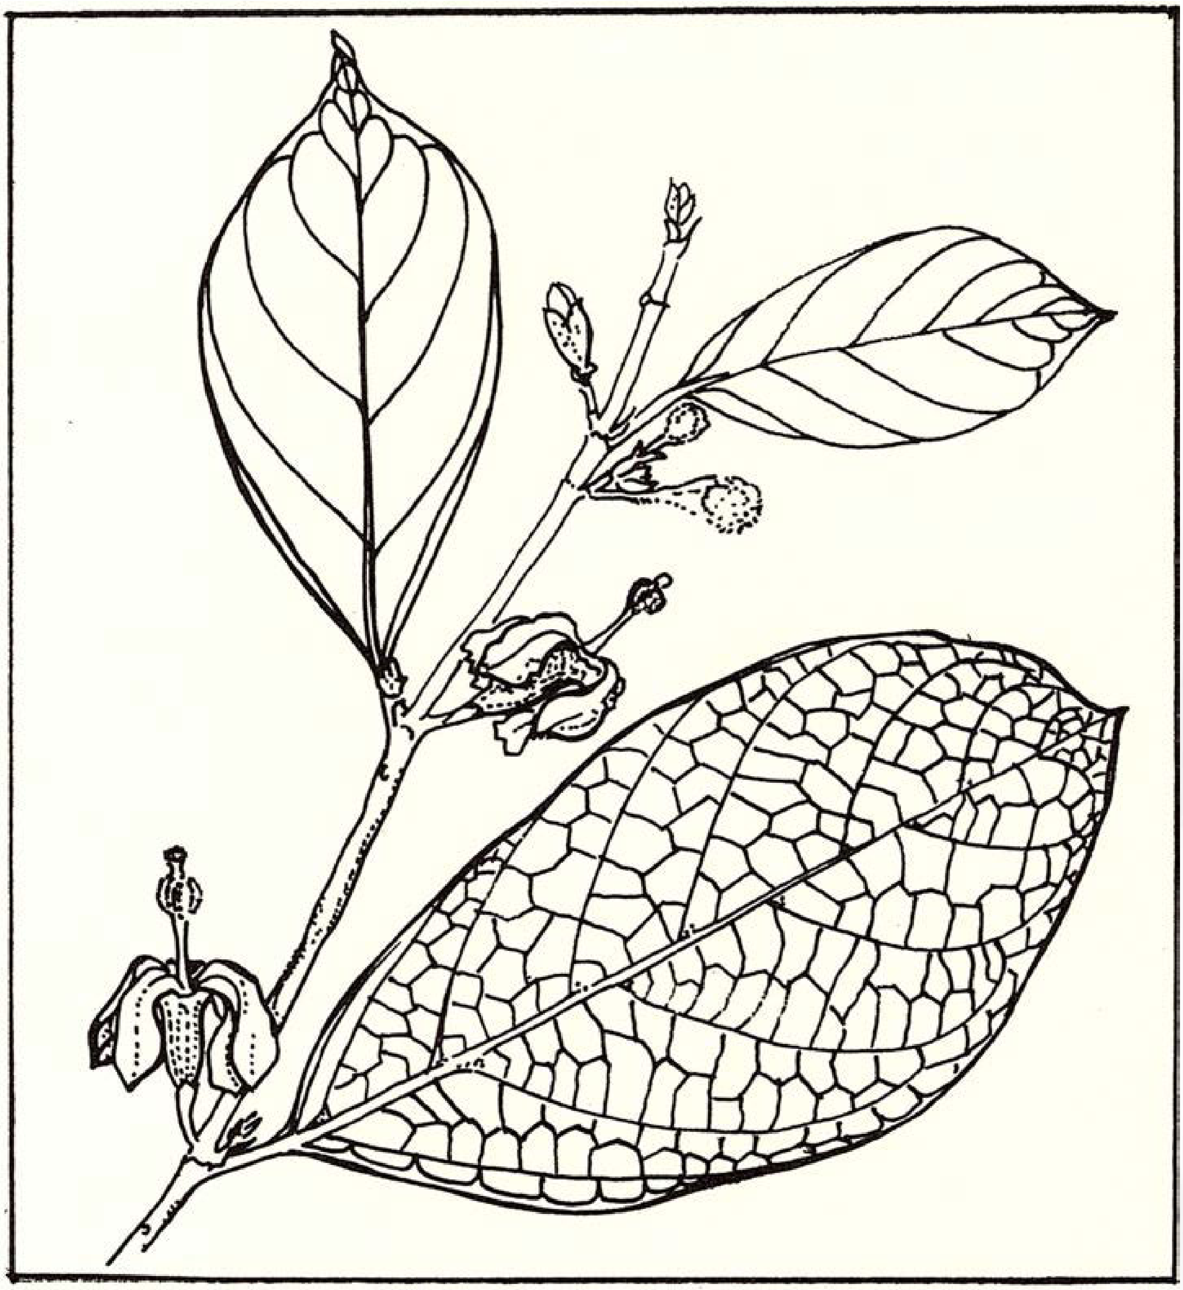

Fig 21 *Quararibea funebris* in flower

The flower is marked by two features - a bold stamineal tube, and *retroussés* petals that leave the tube quite naked. The sculptor of Xochipilli just before the Conquest and Sahagún's artist for the *Florentine Codex* shortly after the Conquest seem to have done their best to do precisely this, though they fell short of the goal they were striving to reach.

---

[18] Though botanists have known the tree for generations, the *poyomatli* has been identified with it only since 1963, when Dibble & Anderson, plodding ahead in their translation of the Nahuatl text of the *Florentine Codex*, came across two independent passages that defined it as the flower of the *cacaltuaxochitl*. Did Sahagún in his paraphrase of the Nahuatl text deliberately omit the identification of this flower that stirred the most intense rapture in Nahuatl circles? See pp 88, 89, 91, also 97 *ff* for further discussion.

We know that the artist in the *Codex* was drawing the *cacahuaxochitl* because the drawing is so labeled. Admittedly the two artists pictured the flowers wretchedly. But let us remember that this tree grows in Veracruz and Oaxaca, not in the Valley of Mexico. Unless the artists knew well the flower *in situ*, they could represent it only by hearsay and by examining the dried pressed blossoms that were carried by porters in bales to the Valley of Mexico. Both artists, after a fashion, managed to catch the distinguishing features - the stamineal tube and the *retroussés* petals - but neither dared picture these as extreme as they really are. Both showed the stamineal tube and Sahagún's artist catches its blunt end. The Xochipilli carving is slightly better than the artist of the *Florentine Codex* in presenting us with the *retroussés* petals. On p 70 we show the flowers as the artists would be familiar with them in dried and pressed condition. With our quick transportation facilities today, we may forget that in pre-Conquest times one had to travel between Mexico-Tenochtitlan and the lands of the *cacahuaxochitl* on foot.

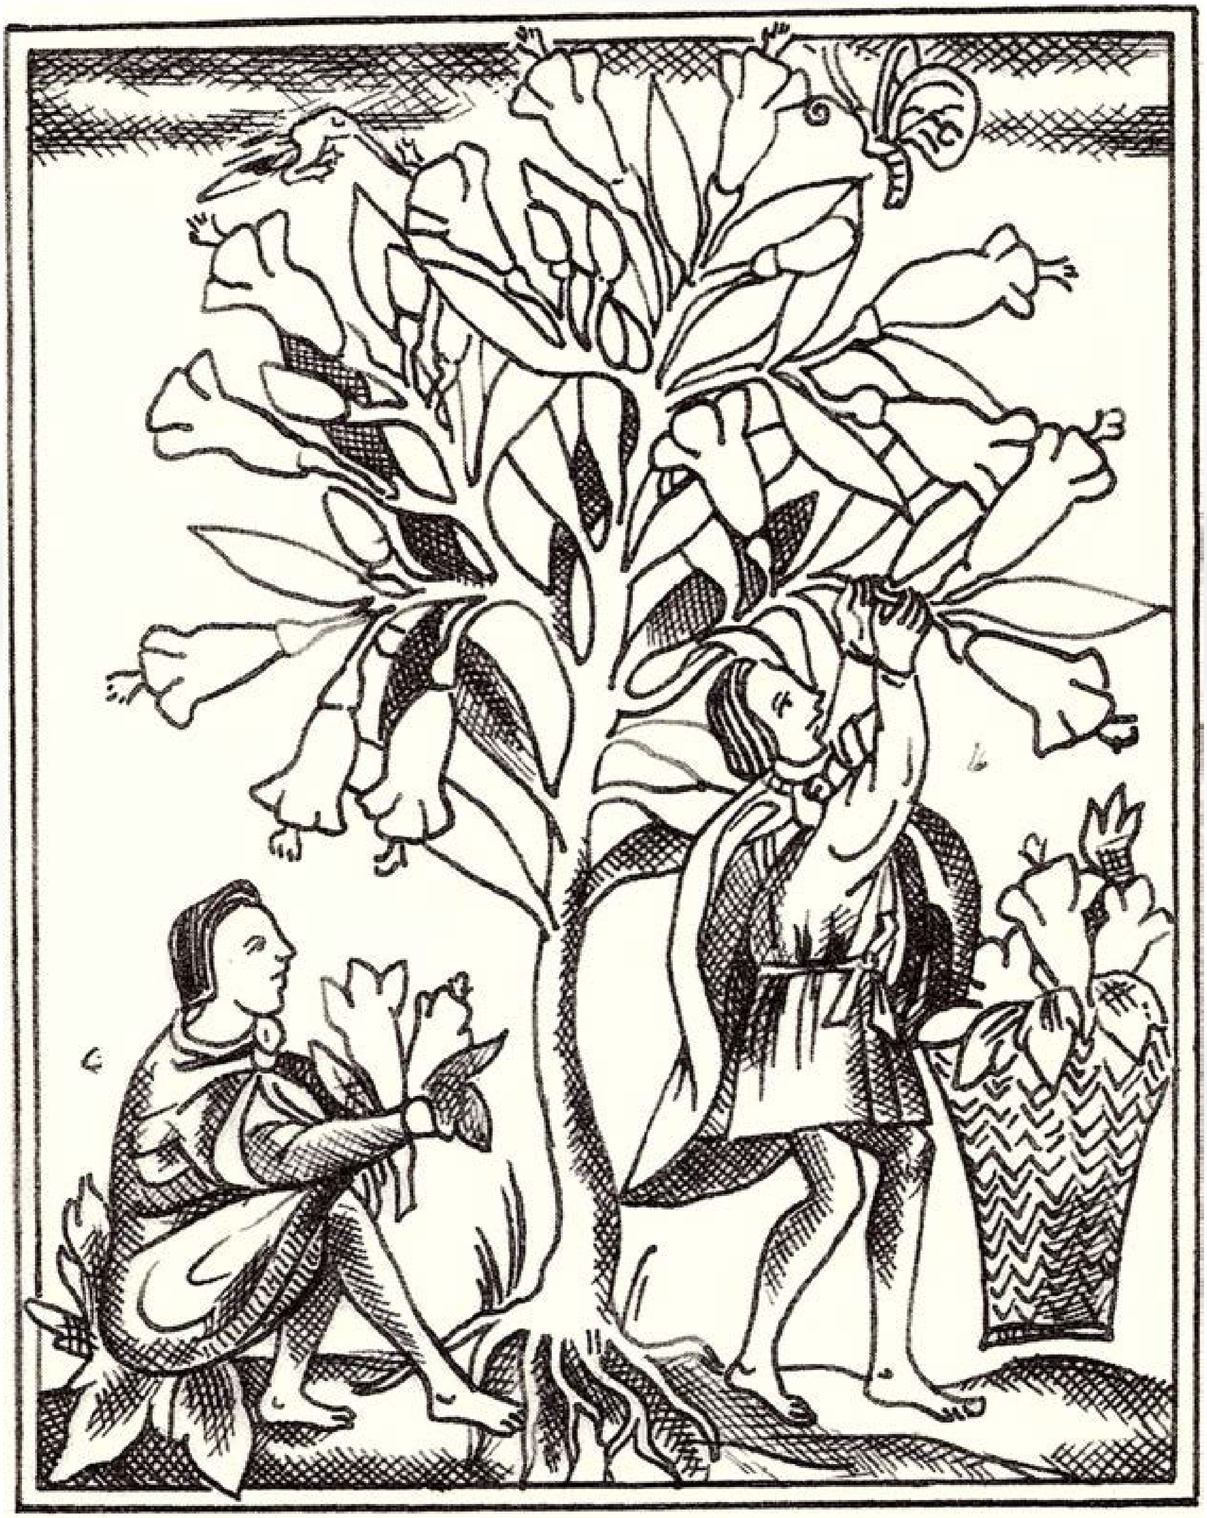

Fig 22 Sahagún's illustration of *Q. funebris*

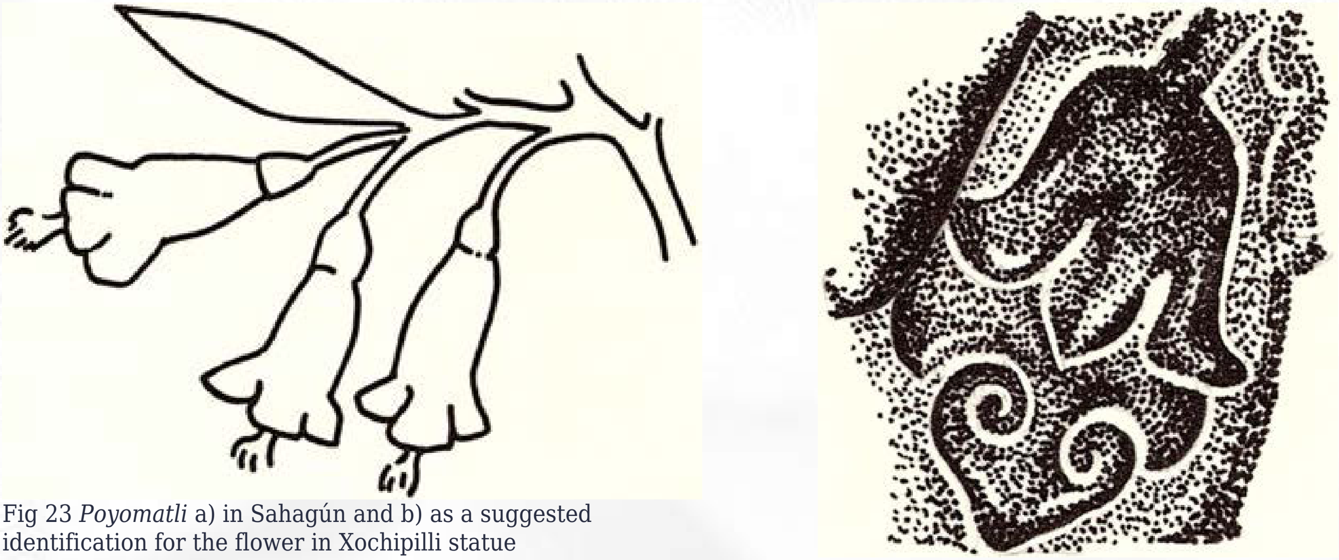

Fig 23 *Poyomatli* a) in Sahagún and b) as a suggested identification for the flower in Xochipilli statue

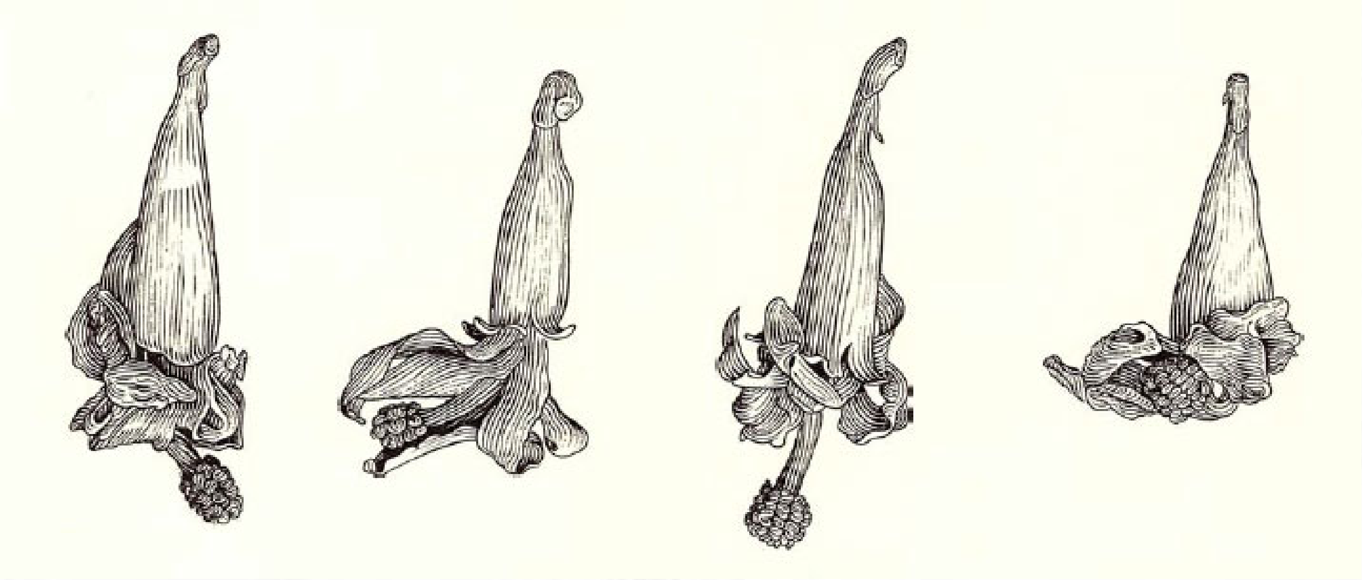

Fig 24 Dried *Poyomatli* flowers

Finally, we discover on our Xochipilli statue, on the inner calf of the right leg, a four-petaled flower. As to its identity we are at a loss. We hope that our readers will come up with a happy suggestion, a flower probably entheogenic, at least a focus of reverence among the Nahua of the Valley of Mexico. Here is Margaret Seeler's drawing of this carving:

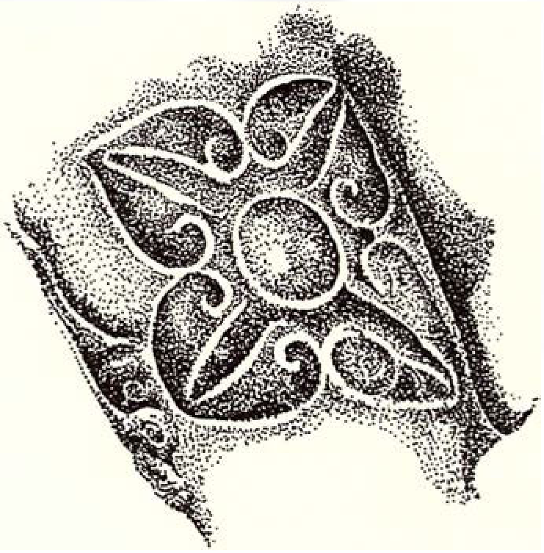

Fig 25 Unidentified carving of flower on Xochipilli

The photograph of this baffling flower was taken especially for us by the Museo Nacional de Antropología.

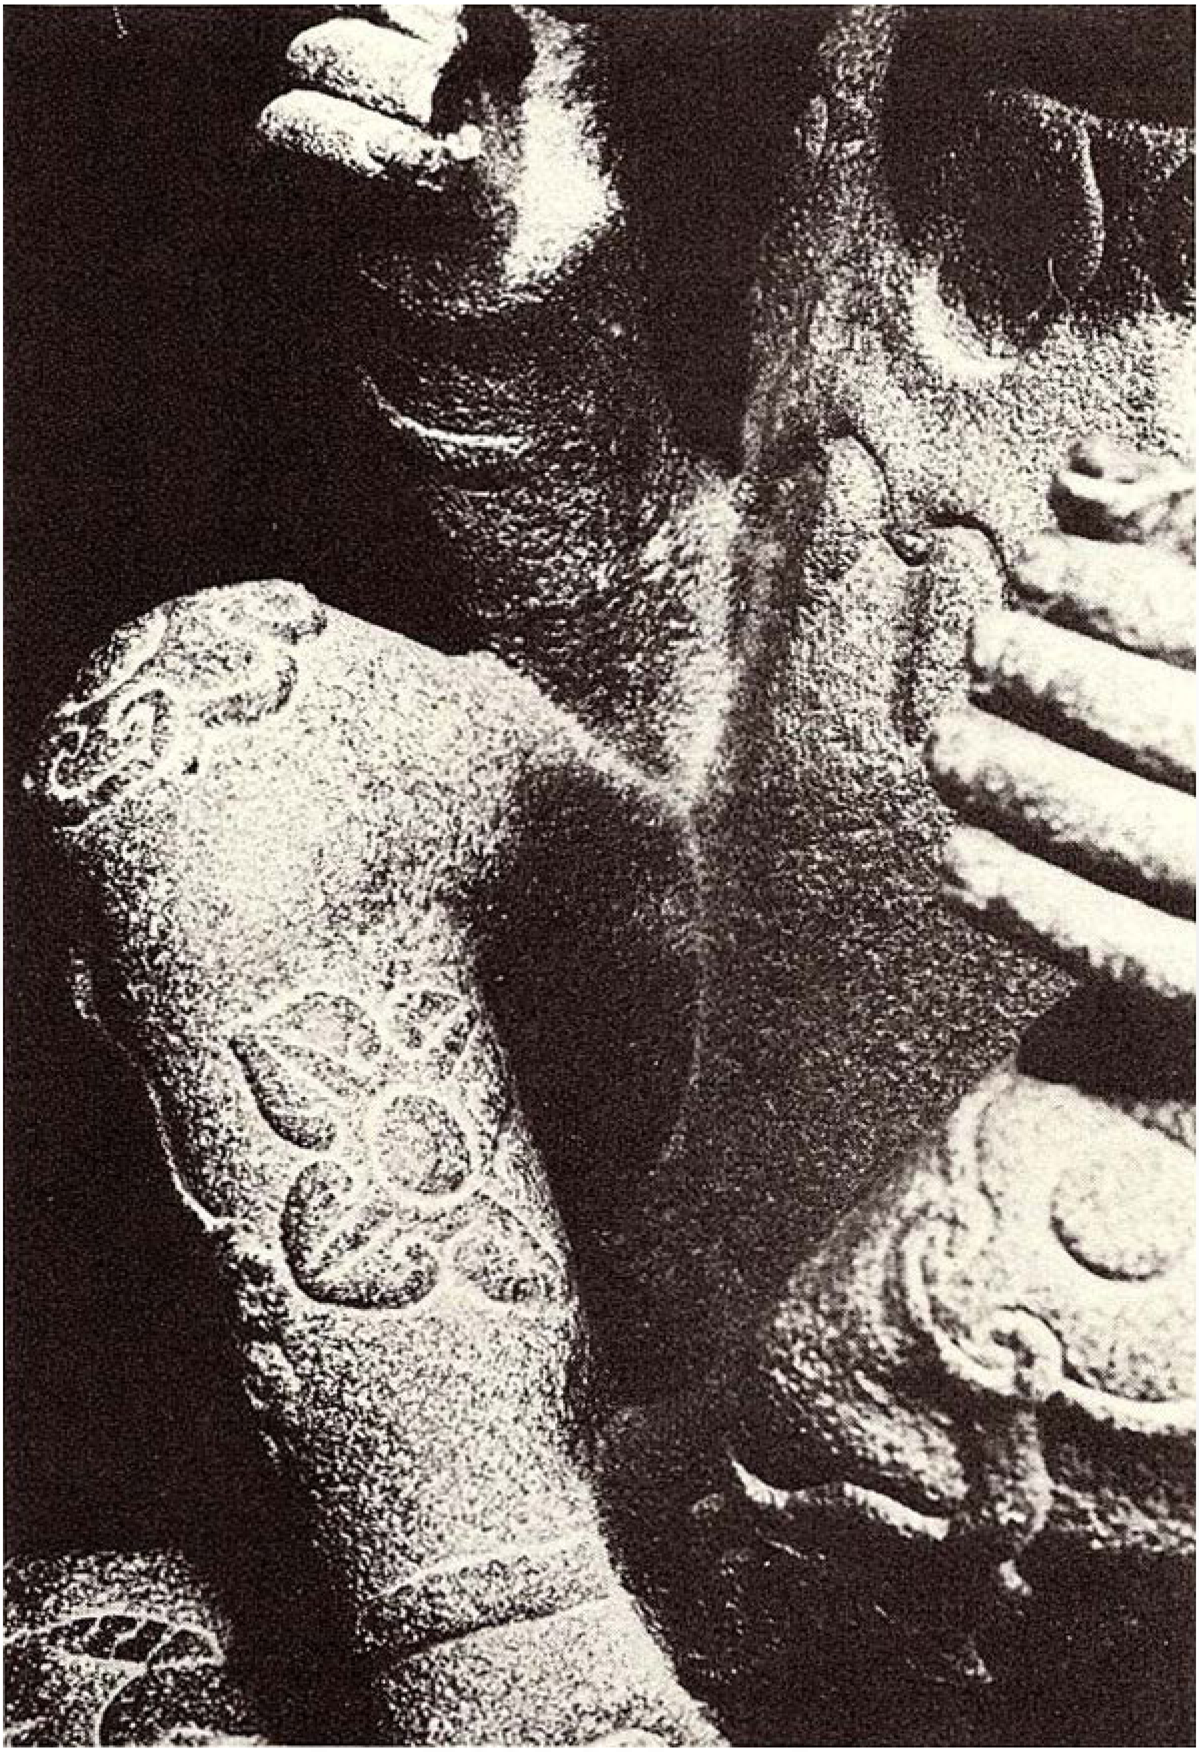

Fig 26 Photo of enigmatic flower

★

The reader will have observed that the 'flowers' carved on Xochipilli bear no fixed relation in size to the flower or mushroom that is portrayed: each flower fills suitably the space allotted to it. The reader will also observe that among the flowers carved on Xochipilli no Datura is represented. The statue expressed the culture of the Princes and Nobles of the Nahua, and the Daturas did not rank with the entheogens of the aristocrats. We also observe that no plant linked with alcoholic beverages - neither pulque nor maize beer - is present.

⋆

About twenty years have passed since I first saw the mushrooms on the 'base' of our statue, but as time has gone by, the mushrooms and other *flowers* have taken second place in my thinking: here in this statue is Rapture itself delineated in stone, and the *flowers* only serve to confirm its meaning. The *flowers* on the *tablero* and body (among which the mushrooms receive pride of place!) amply ratify, for doubting Thomases, the identification I have given to Xochipilli, the God of Rapture. The elegance of this statue, its subtlety, its nobility, speak for the exalted place accorded to the entheogens by the *élite* in pre-Conquest Mesoamerica. They emphasize the surprising ignorance and lack of respect shown by all Mesoamericanists for this major manifestation of the civilization that is their special field of study. In his paper on our statue of Xochipilli Justino Fernández begins by denying the ecstasy of this statue and to that end would introduce turquoises into the eye-sockets, but even he finally compromises his position by succumbing to the enchantment of the face:

> Por último, el gesto de la máscara tiene tensión dramática y cierta ternura, pues la mirada está pendiente de algo 'más allá', que parece mirar fijamente...; el gesto de la boca tensa horizontalmente y con los labios un poco entreabiertos sugiere cierto esfuerzo de elevación,...
>
> Finally, the mask shows dramatic tension and a certain tenderness, since the look is one of expectancy of something from 'out yonder', where its gaze seems fixed...; the expression of the horizontally taut mouth with half open lips suggests a certain effort at elevation,...

How close did this able academic art critic come to the esoteric meaning of the statue! Here he seems to have finally abandoned his notion of turquoises in the eye-sockets: he concedes that the 'gaze' is fixed 'out yonder'. If only he had had the entheogenic experience, or alternatively if only he had stopped to examine the botanical specimens carved on this ensemble of noble statuary!

Perhaps the reader will have allowed himself to be persuaded by my presentation of Xochipilli without due regard to the consequences: let him be warned. If he accepts my interpretation, he will be committing himself to a reappraisal of pre-Conquest Mesoamerican culture. For going on five centuries those interested in Mesoamerica have ignored the entheogens. The Indian informants of the Spanish chroniclers, knowing well where their bread was buttered, gave accounts of the entheogens that lent themselves to due execration by the ecclesiastical scribes. We must be grateful that the informants tell us as much as they do and that the friars pass on to us, more or less faithfully, what they were told.

Xochipilli appears often in the pre-Conquest codices and sculptures of Mesoamerica but the artists naturally felt no need to spell out his meaning. Let me suggest an analogy: the ancient Egyptians used methods of writing that no one could interpret until there was found in 1799 a stone in the delta of the Nile with a text engraved for contemporaries in three modes of writing, in Greek, and in Egyptian hieroglyphics and demotic script. From this bilingual inscription the Frenchman Champollion started us on the road to reading the vast corpus of ancient Egyptian texts. Those who carved the Rosetta stone were not thinking of the use to which it would be put by learned men in distant lands far in the future; neither could the artist carving Xochipilli have imagined, if I am right, what a sensational disclosure his work would be making to strangers from another world half a millennium later. Here Xochipilli discloses the exalted view of the entheogens held by the Mesoamericans in pre-Conquest times: the nobility of this statue speaks loud and clear, with the honesty of all outstanding works of art. Later, some of the friars with distinguished talents and extraordinary zeal leavened with compassion and even admiration for the conquered, wrote down lengthy accounts of life in Mesoamerica before and after the Conquest, but always filtered through the theology of their time and circumstance: inevitably they gave no quarter to the entheogens. Our statue of Xochipilli serves us as a touchstone, as a cultural Rosetta Stone, bypassing the friars encumbered with their theological preconceptions, speaking to us directly with the voice of the pre-Conquest Aztecs.

As an artist's expression of ecstasy in Mesoamerica our Xochipilli is far from unique. He is unique only in that his body bears carvings of the miraculous plants that transport him and us to another reality and that spell out for us his message. In Colima Dr Isabel Kelly has unearthed a number of small stone statues bespeaking rapture with a breathtaking eloquence perhaps unmatched even in our Xochipilli. They date from the end of the seventh century A D. Surely the absence of the plant carvings on their bodies does not negate for us their meaning. Their eyes are open, as is not unnatural in a nocturnal *velada* held in the dark. Two of them are on exhibit in the Museo Nacional de Antropología. (Figs 27, 28)

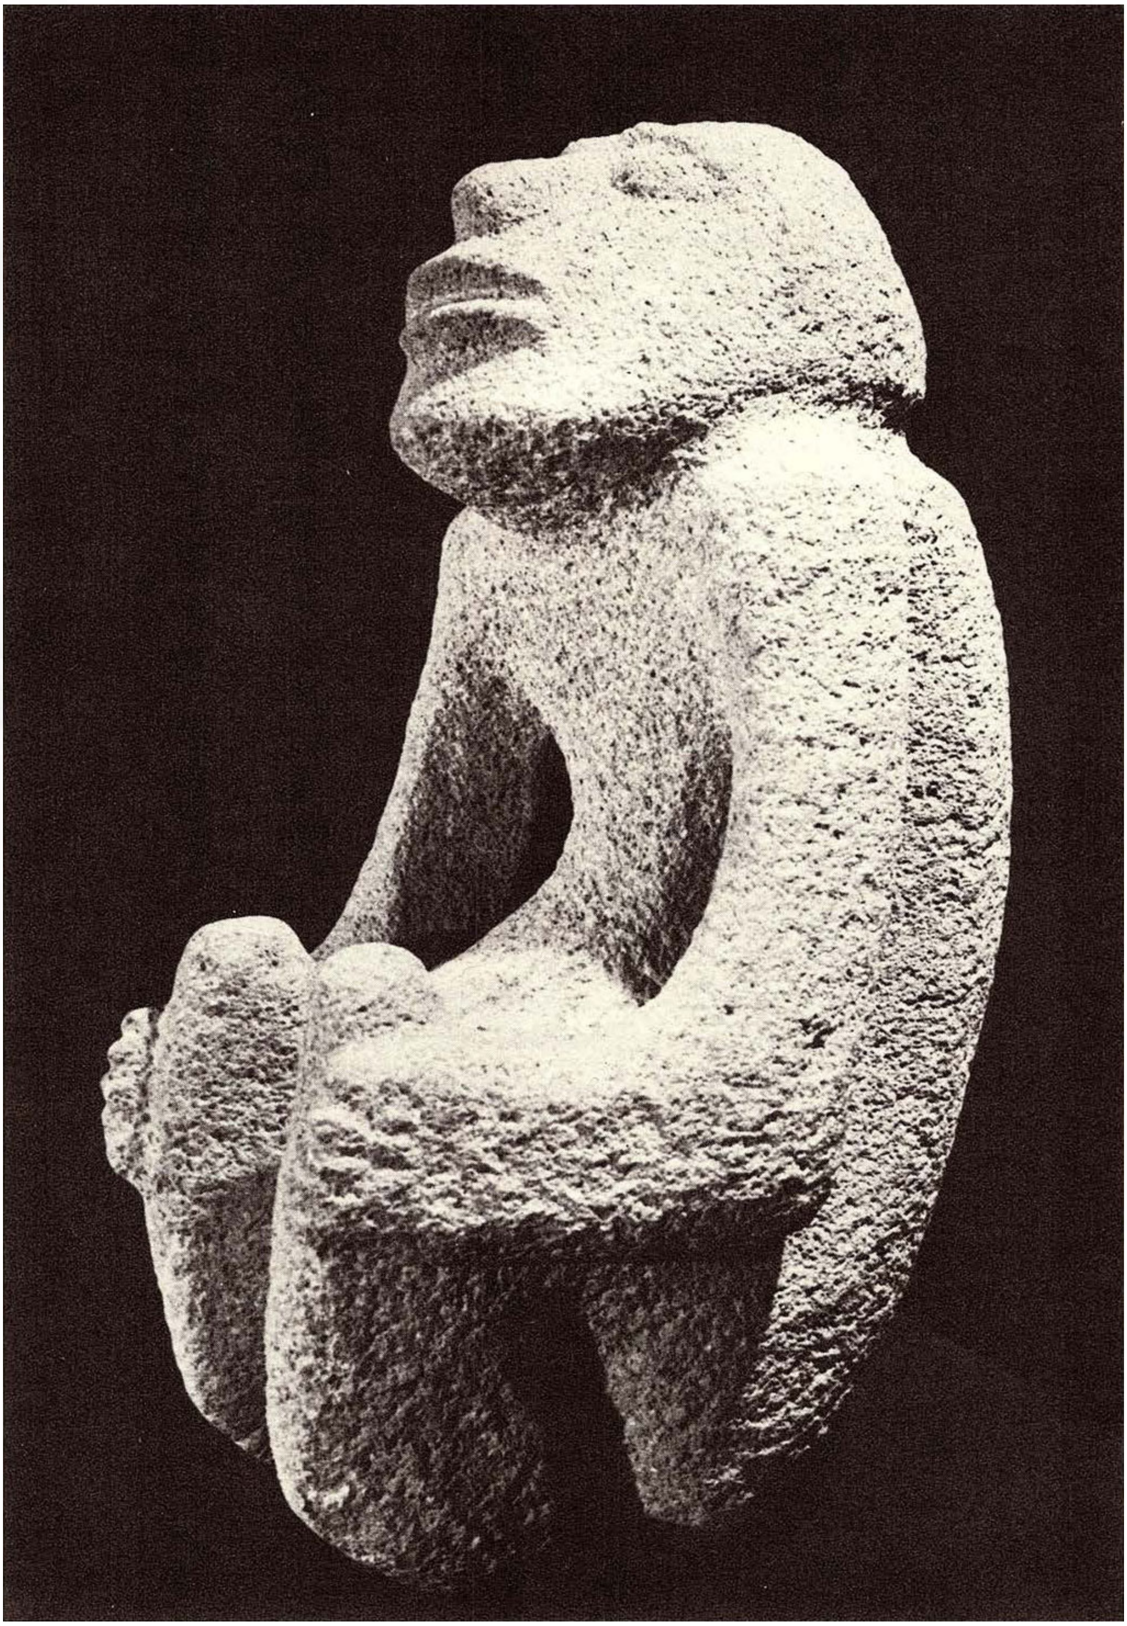

Fig 27 Stone carving of ecstasy

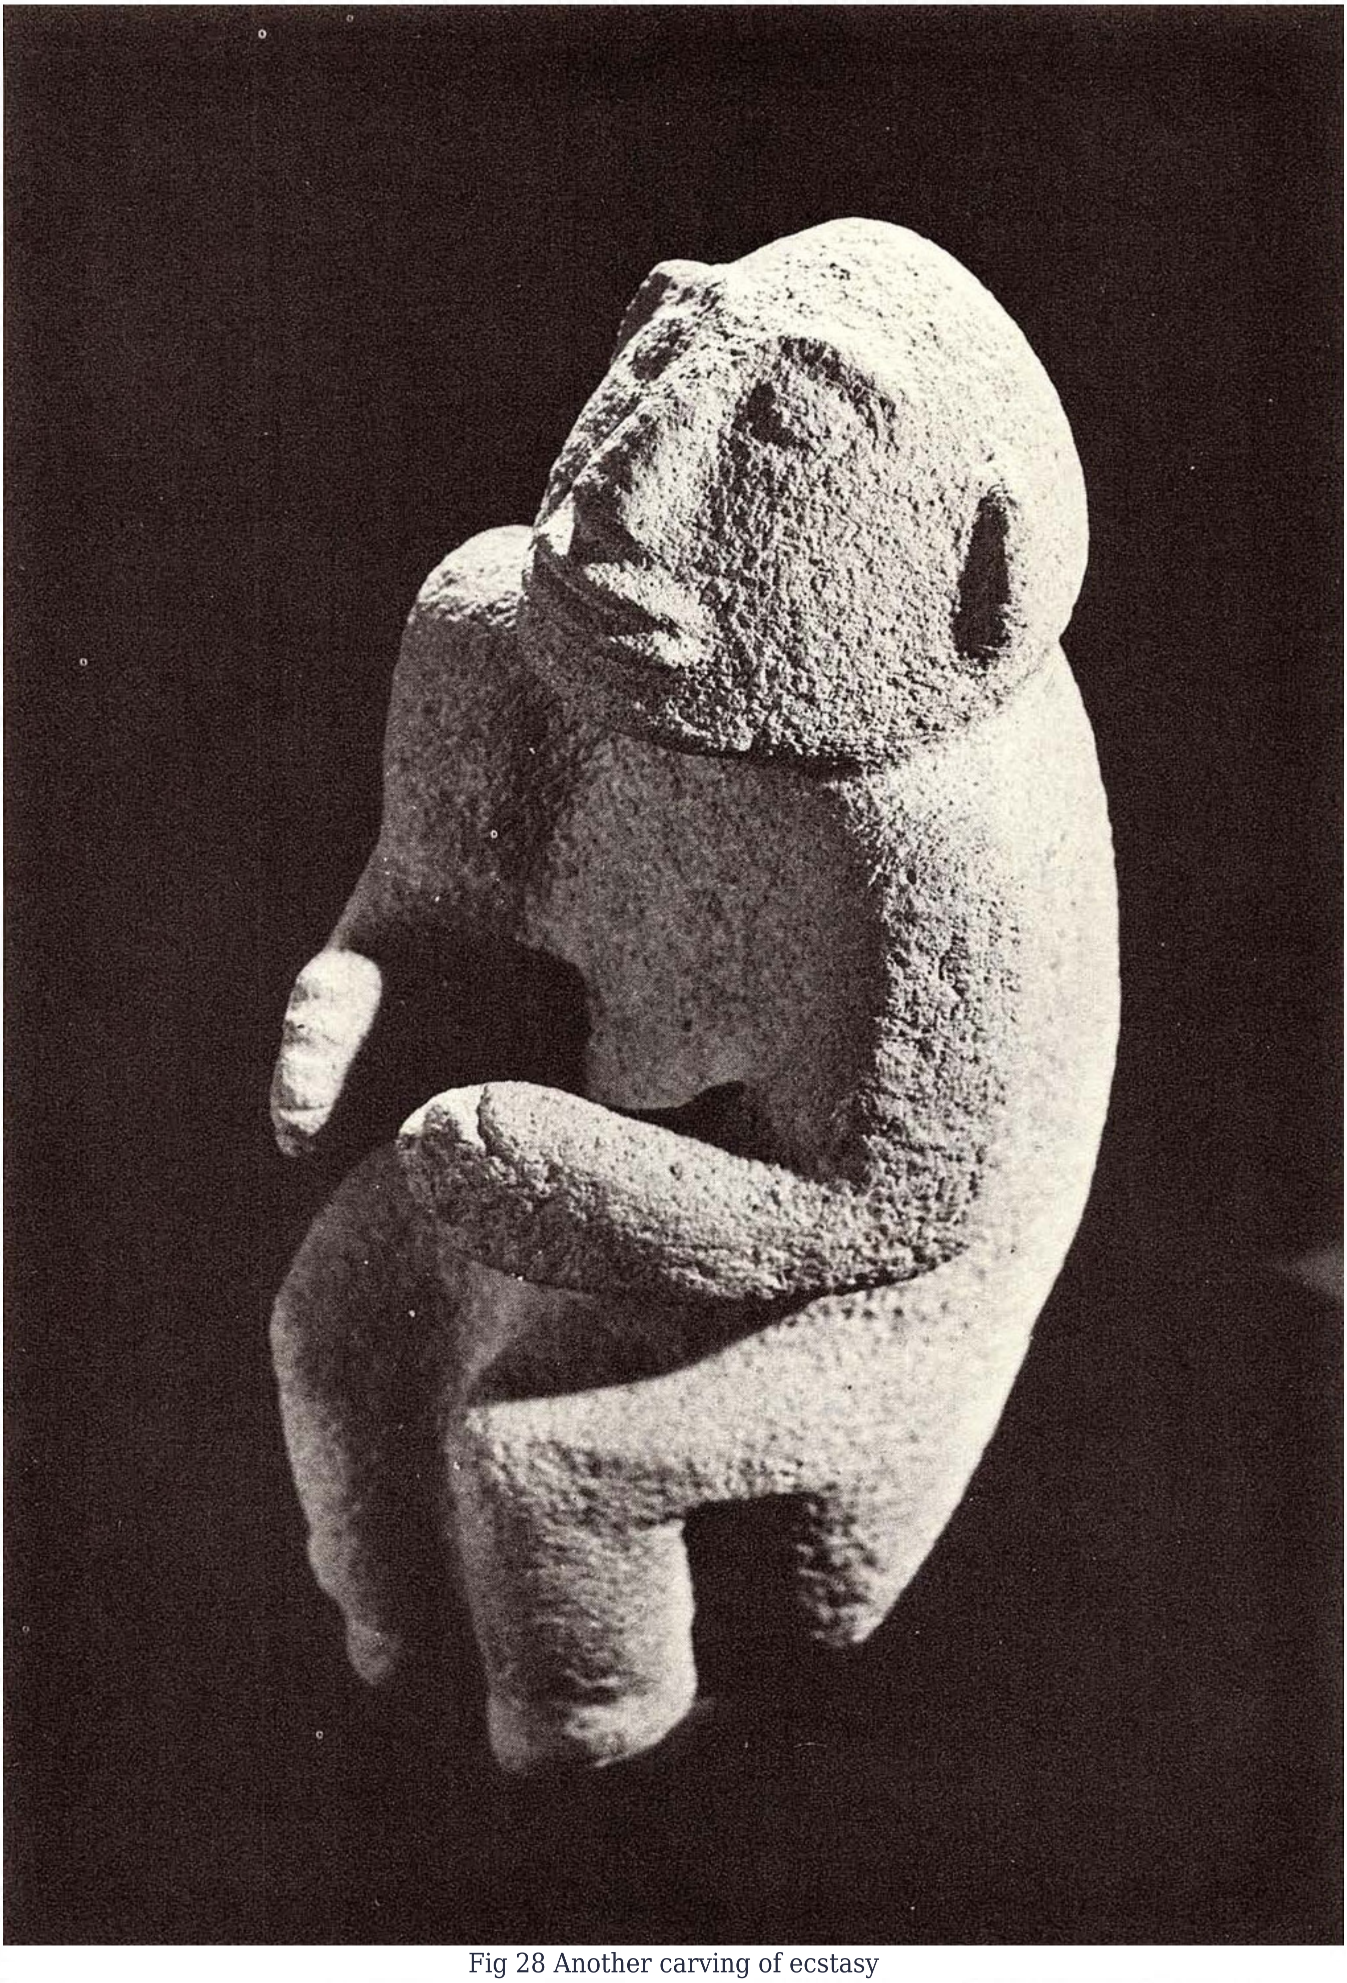

Fig 28 Another carving of ecstasy

I think there were two ways of presenting ecstasy in pre-Conquest Mesoamerica. We have seen the grand manner in the Tlalmanalco Xochipilli and the two Colima figurines. This style conveys to the spectator the awesome experience that follows ingestion of the entheogens, but in doing so it translates reality on to a transcendental plane. Those who are experiencing the entheogens actually sit as in a stupor, rapt in their own sensations, their facial expression introverted. In the Museo Nacional there is a Mezcala figurine (Fig 29), eyes closed, carved in hard stone, and dating from the late pre-classic period, B C 600-100. Some may question whether this Mezcala artifact is an embodiment of rapture, so blank and negative is his expression, but I ask what else can it be? For those who have known the mushrooms or the morning-glory seeds, it takes no effort to imagine his state of mind. The artist who carved Xochipilli was giving us reality transfigured, was giving us what the Indian would feel that he was living through, was giving us Rapture petrified. The mask tells us what the man in ecstasy felt. The artist of the Mezcala figurine tells us what the same man looked like to others.

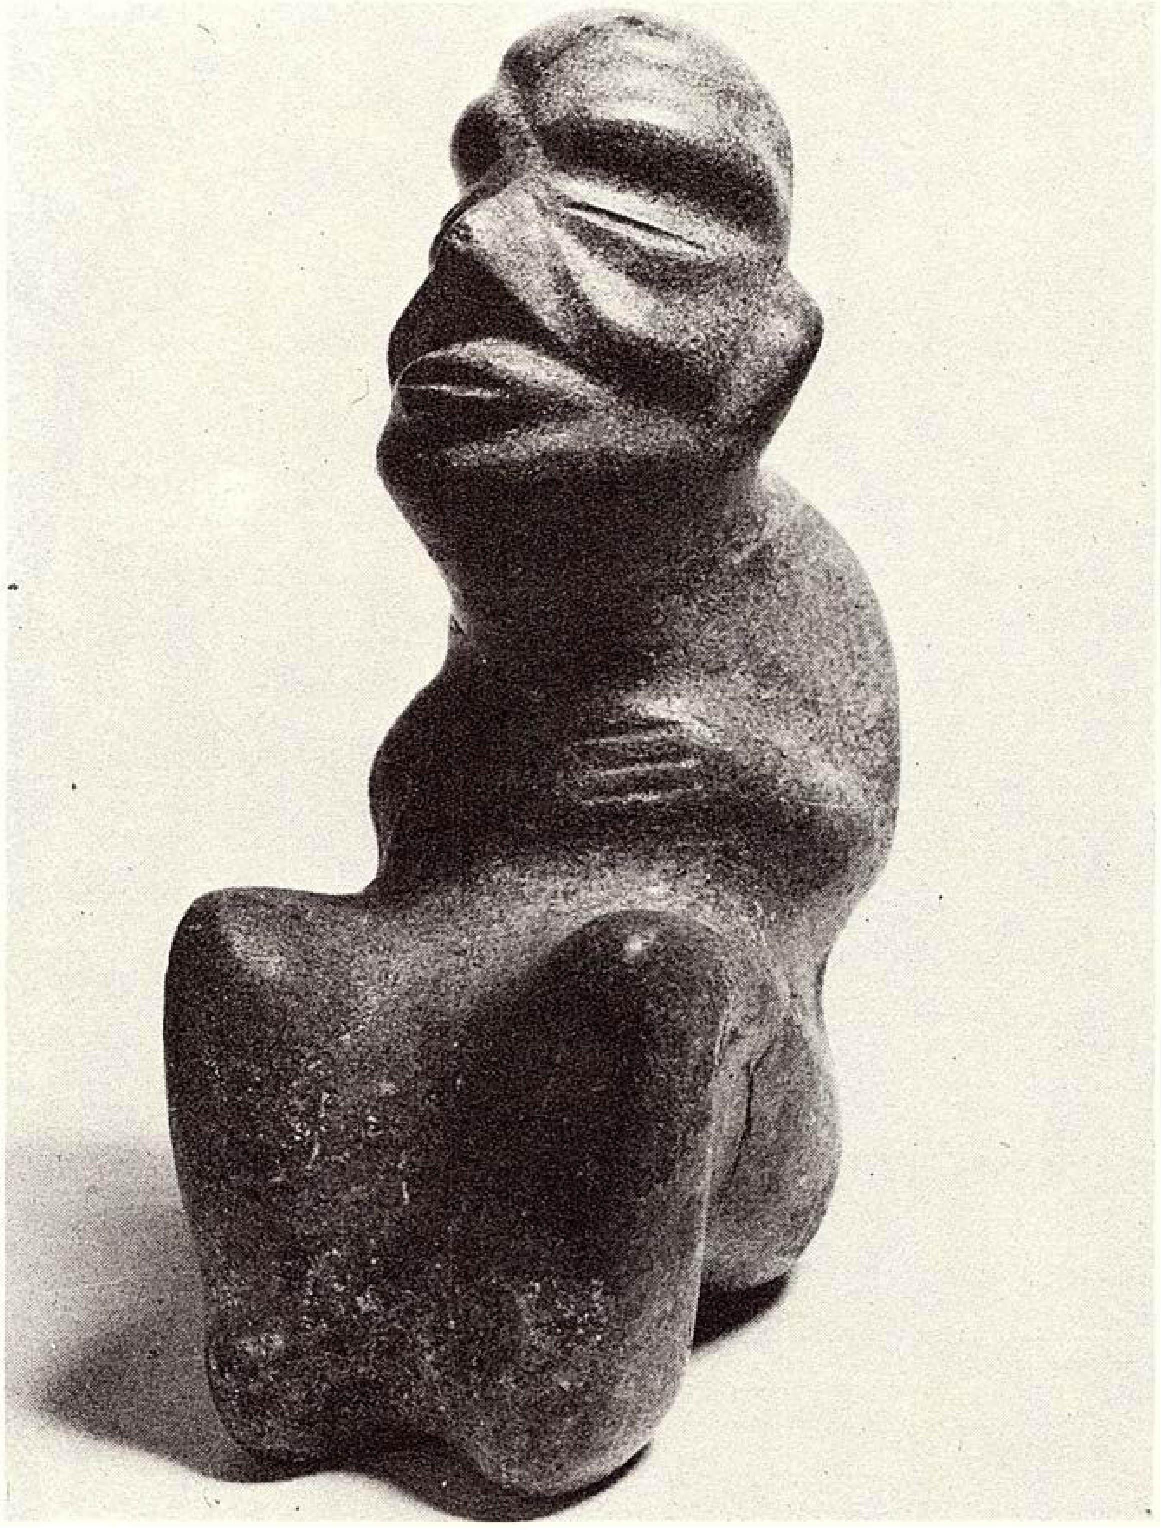

Fig 29 Another interpretation of ecstasy

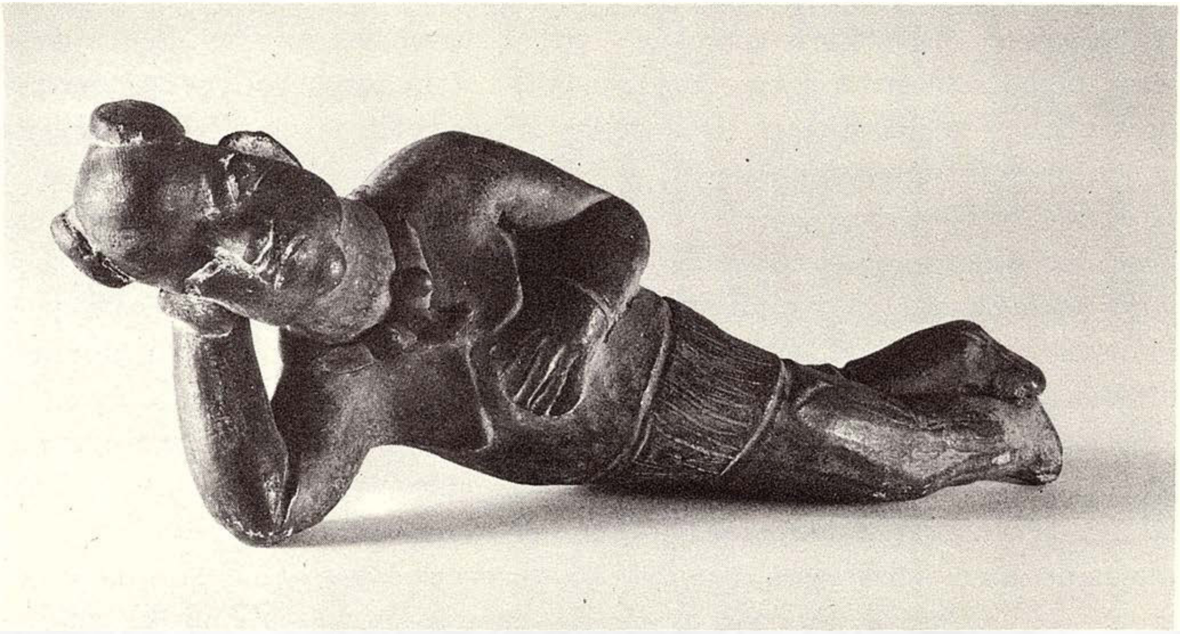
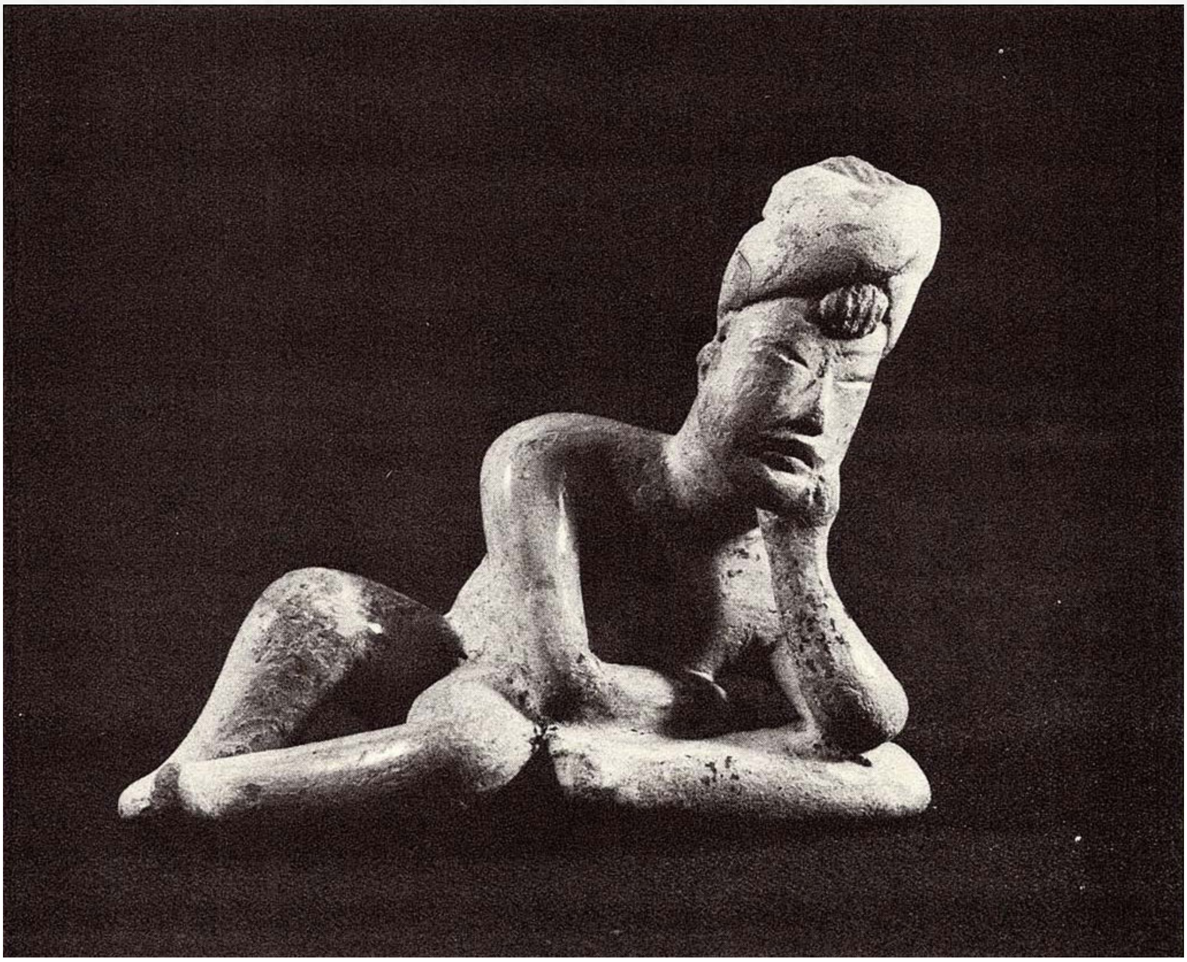
The late Dudley Easby and his widow Elizabeth, with the prescience that always characterized their work in Mesoamerican archæology, grouping together a number of small reclining figures, suggested that these particular figures and others like them might well represent ordinary people enjoying the entheogenic experience. Those that they reproduced in the Catalogue of the *Before Cortés* exhibition in the Metropolitan Museum were in jade (possibly Olmec) or clay. (Figures 30 and 31) They range from 3½ to 8½ inches long and date from the middle or late preclassic period (BC 1150-100), hailing from Honduras, Central Mexico, and Guerrero. I have no reason to think that the Easbys had ever known a *velada*, had ever taken the entheogens, but they were gifted with rare intuition and their surmise may well have been right.



Figures 30 and 31 Figurines expressing ecstasy (?)



How different all these expressions of the ineffable are from the manner of the European religious painters of the late Middle Ages and early Renaissance! For them the Saint is leaning forward on his knees, arms outstretched, his eyes lifted heavenward, perhaps toward a vision in the radiant sky of the Virgin with her supporting heavenly host singing sweetly to the accompaniment of divers musical instruments and with *putti* scattered among the clouds. This was the Western conception of beatitude, of bliss, executed often by able artists but artists who had never experienced what they were painting. In Mexico the artists knew what it was they were carving and by the simplicity of their execution they succeeded in conveying to the viewer (who also knew) the sense of the rapture that their opposite numbers in Western Europe could not approach.

The statue of Xochipilli tells us that *xochitl* could mean in Nahuatl, as a figure of speech, the entheogens and the incomparable wonder-world to which they invite us. The *flowers* carved on the body of this our exemplar of ecstasy are what the Mesoamerican Indians regarded as sacred entheogens. Miguel León-Portilla comes as near to arriving at the truth as one can hope to do who has not known the miraculous plants, has not allowed for their existence: he skirts, but only skirts, in every word of the following eloquent passage, the genuine meaning for the Nahua of *xochitl* in its metaphorical sense:

> La expresión idiomática, *in xóchitl*, *in cuícatl*, que literalmente significa 'flor y canto', tiene como sentido metafórico el de poema, poesía, expresión artística, y, en una palabra, simbolismo. La poesía y el arte en general, 'flores y cantos', son para los *tlamatinime* [wisemen, Magi, soothsayers], expresión oculta y *velada* que con las alas del símbolo y la metáfora puede llevar al hombre a balbucir, proyectándolo más allá de sí mismo, lo que en forma misteriosa, lo acerca tal vez a su raíz. Parecen ['flor y canto'] afirmar que la verdadera poesía implica un modo peculiar de conocimiento, fruto de auténtica experiencia interior, o si se prefiere, resultado de una intuición.
> [Los Antiguos Mexicanos, Chap 4, p 128 in my reprint; Fondo de Culrura Económica, Mexico, 1961.]
>
> The idiomatic expression, *in xóchitl*, *in cuícatl*, which literally means 'flower and song', has the metaphorical sense of poem, poetry, artistic expression, in a word, symbolism. Poetry and art, 'flowers and songs', are for 'those-who-know' [wisemen, Magi, soothsayers] an occult and veiled term that may sweep man off on the wings of symbol and metaphor, stammering, may project him beyond himself, thus perhaps in a mysterious manner bringing him nearer to his origins. '*Flower and song*' *seem to affirm that true poetry implies a peculiar way of knowledge, the fruit of an authentic interior experience*... [Italics mine]

This 'peculiar way of knowledge', this 'fruit of an authentic interior experience'! Leon-Portilla divined the truth. Without knowing it, he was describing a *velada* with entheogens.

CHAPTER 4

The *flowers* in pre-conquest nahuatl poetry

The corpus of pre-Conquest Aztec poetry began to be accessible to the West only a few years ago and almost at once it was remarked that this poetry possessed a feature peculiar to it: on 15 May 1961 *The Times* (London) in a dispatch from Mexico City observed that the Aztec poets never tired of talking about 'flowers' but that they seldom distinguished one species from another. Since poets are prone to subtleties in thought and feeling, this lumping together of 'flowers' was odd. No explanation was forthcoming from the Nahuatlatos (as specialists in Nahuatl are called) and none has been advanced since then. But if the Aztec Princes and Nobles, who were the poets that we are speaking about, used 'flowers' as a figure of speech for the entheogens and the entheogenic experience, in short if the poets understood 'flowers' as the Xochipilli carvings say they were to be understood, all becomes clear. (I am printing *flowers* in italic when we deal with a trope for the entheogens.) The *flowers* were the breathtaking experience of their lives, supreme and miraculous. The *flowers* took them to another world where they sang their Aztec poetry to the music of their Aztec instruments, a world that they called their Tlalocan (or sometimes their Tamoanchan), a world of strange and wondrous beauty, where they reveled in sensations beyond imagining. It is not surprising that these Princes and Nobles, able and sophisticated men, composed poetry weighted with *flowers*.

The Times's correspondent exaggerated: specific flowers are cited in Nahuatl poetry as often as in any other. What is distinctive is the recurrence of *flowers*. In the four volumes of Nahuatl poetry that I shall discuss *flowers* are iterated and reiterated times without number. *Flor* y canto, '*flower* and song', drew the poets, according to Diego Durán, to their periodical gatherings around their symbolic 'Tree-in-*Flower*' - *xochicuahuitl*, *Arbol Florido* - and to the house of flowers - *xochicalli* - where on the feast of Xochipilli a 'tree' was erected *ad hoc* and laden with flowers, where children dressed as birds and butterflies gamboled among the flowers, and where everyone sang and danced. This custom had been going on for perhaps a thousand years, for at Tepantitla, in Teotihuacán, the fragments of a mural of this stylized 'tree' were found in the late 1930's, and Villagra Caleti conscientiously restored it for display in the Museo Nacional de Antropología. Peter T. Furst suggests that this tree represented the morning-glory. He is certainly right in part: the interlacing branches take their inspiration from the twining climber of the Nahuatl *coaxihuitl*, 'snake plant', the morning-glory, whose seeds are known as *ololiuhqui*. But this 'Tree-in-*Flower*' is a symbolic tree built for the occasion, and the Nahua erected it to the glory of all the superior entheogens among which the morning-glory held a most honored place. Diego Durán does not say that at this celebration the participants consumed entheogens but his failure to do so leaves the question open and in the light of our meaning for Xochipilli, Prince of *Flowers*, and of Durán's obvious implication (discussed on p 201) that *flowers* were present when he does not expressly mention them, it is not an abuse to surmise that *flowers* were there consumed. Indeed, their presence is compelling.

We reproduce Villagra's repainting of this 'Tree-in-*Flower*' in Fig 1. The Mesoamerican conception of such a tree reminds us forcibly of the Maypole in northern Europe, where in Sweden it is still decorated with branches of birch. Those who celebrate the Maypole no longer remember that the birch is the host of choice to the entheogenic *Amanita muscaria*.

All students of Nahuatl culture have become familiar in recent times with the word *teonanácatl*, the name used for the entheogenic mushrooms that was used by Sahagún and Motolinía. But we ask ourselves why this word is not to be found in Fray Alonso de Molina's big lexicon of the Nahuatl language published in 1571. He gives us another word, *xochinanácatl*, '*flower* mushroom' from *xochitl*, 'flower', precisely the word that the statue of Xochipilli tells us to expect. *Xochinanácatl* survives to this day in a place name, 'Xochinanacatlán', a *muncipio* of Tlaola, District of Huachinango, State of Puebla. 'Nanacamilpa' is a place name near Tlaxcala even now and there is authority for the belief that in Veracruz a village existed in the sixteenth century called 'Nanacatlan'. One Antonio Xochinanácatl figures in a Tlaxcala law suit that Thelma Sullivan is translating. In the *Matrícula de Huexotzinco* (a bilingual list of that town's inhabitants in 1560 composed in Nahuatl picture-writing and in Spanish) two men bear the name Xochinanácatl. (See p 114)

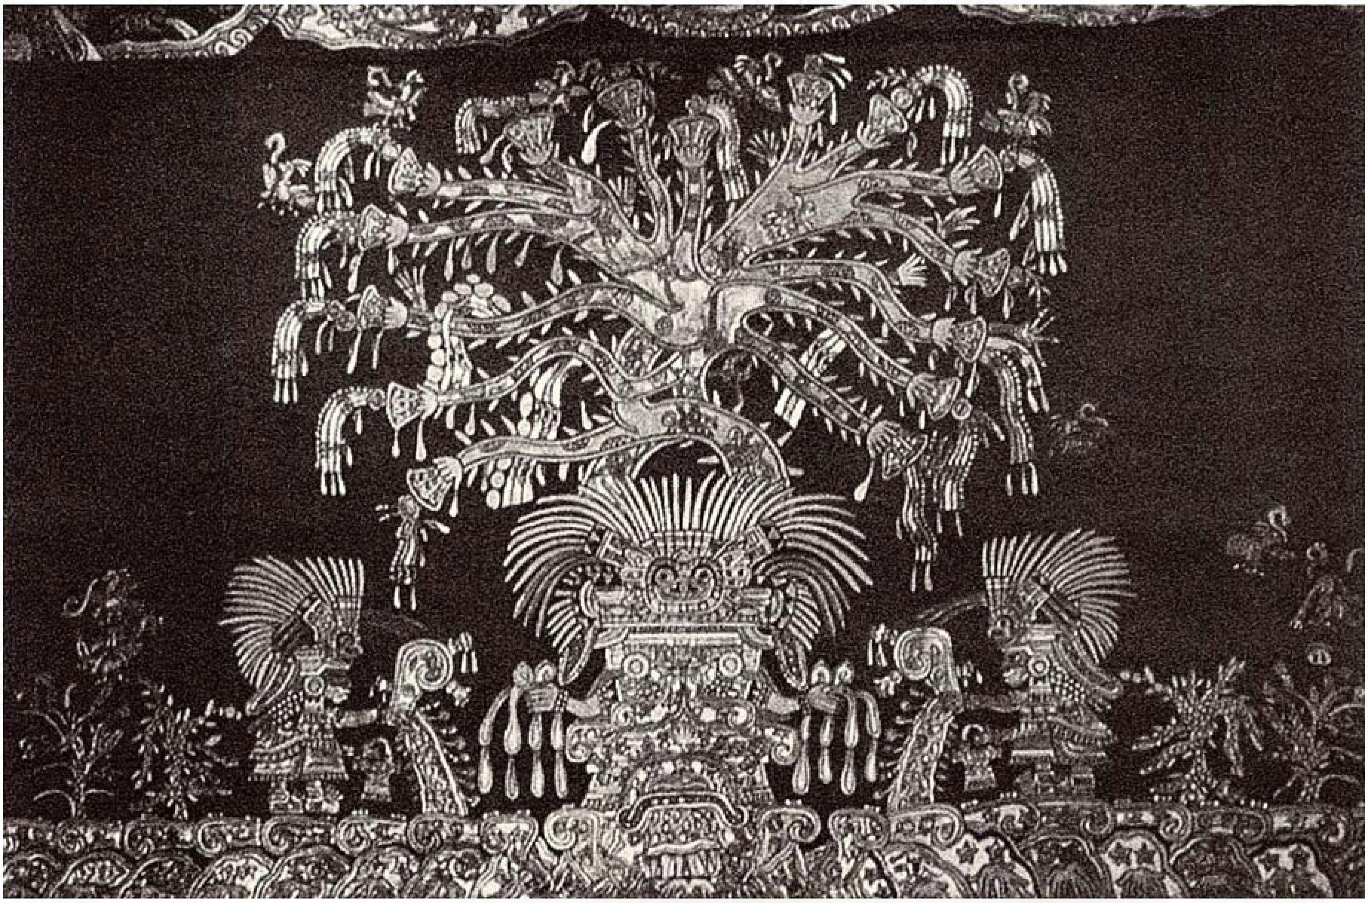


Fig 1 The Tree-in-*Flower*, repainted after Tepantitla, Teotihuacán

In Mesoamerica we enjoy an inestimable privilege: we have spread out before us the life style of a branch of Early Man possessing an advanced culture, the leader among the cultures round about, where any immediate influence of Eurasia is most unlikely, where earnest and zealous scholars believing in such influences work all their lives to establish threads of ancient contact, where such contacts (and certainly there may well have been some) do not materially affect the pure strain of what the Spaniards found flourishing in Mesoamerica. They found a people for whom religion was everything, perhaps even more so than for the sixteenth century Spaniards: no human act was performed untinctured by religious beliefs. Their religion evoked reverence, adoration, awe, but also fear, yes, and terror; as do all religions gripping Early Man. Their 'wars' were often waged solely to take prisoners to sacrifice to their gods. The frenzy, the delirium, of these wars, the dangers that every warrior ran, the courage that the prisoner was expected to show on the sacrifice day, added to life the ultimate in awesome terror. Their cruelty was clean, elegant. When prisoners were being sacrificed with the obsidian knife on a stone slab carved for that purpose, on top of the pyramids, the enemy's leaders would be invited to attend and from behind blinds they would watch the victims climb the long, steep, shallow steps without balustrade to meet their end at the top. (How bitter-sad and proud must their compatriots have been on watching the behavior of their friends and loved ones on this, their last glorious day!) The Nahua were cruel, but who are we to reproach them?

We discover that '*flower*' was also used as a trope for their warfare, just as it was for the entheogens. The Nahua exalted their 'wars' with this their supreme metaphor of enhancement, taken from the metaphor for the entheogens. The entheogenic experience was the supernal event of their lives and it supplied them with a storehouse whence they drew their ultimate in verbal praise, redolent with religious feeling. They believed in the reality of that other world of the entheogens, and anyone who knows the mushrooms and is also imbued with historical imagination will understand why. We must always keep in mind what Early Man did *not* know: the Nahua did *not* know they were dealing with a mere 'drug', as we say, a chemical compound with a known molecular structure and a known impact on the human mind. They were dealing with a miraculous, a divine gift. The two tropes - primary and secondary - became interchangeable in a way sometimes difficult for us to follow: there is interplay between them, to the point where we can sometimes only guess at the meaning.

Father Garibay expressly denies to his four volumes of poetry any involvement with the entheogens, even when the inebriating mushrooms (*eg nanacaóctli*, 'mushroom liquor') are specifically mentioned, saying that here we have to do with poetic metaphor. But how jejune, how flaccid, is this poetry stripped of the divine inebriants! In these verses our Nahua, Princes and Nobles, are treating us to the hot afflatus of poetic passion, courtly poets living in their own proto-history without the alphabet, composing and singing their own verses before they knew that Europe existed, and what preoccupied them? The Mystery of the entheogens. Here lie the bone and sinew, the blood and muscle of their poetry. They were aglow with the rapture of the entheogenic experience, the religious surge that welled up in them. In this corpus of Mesoamerican poetry we discover Early Man's poetic drive uninfluenced by Eurasian peoples. We surmise a practice and an intellectual legacy from those migrants who came across the Bering Strait, but this takes us back many, many millennia.

If there are any who question my meaning for these poems, I urge them to read the first four poems that I off er in this chapter and then to say whether the poets were singing merely to the fragrance of flowers. They were not only cultivated men but men of power in their world. Effeminacy is not a word that could be linked to them.

The paradise of the Nahua is mysterious alike for them and for us, but the questions it poses for them and for us are radically different. Knowing nothing of this other-world of Mesoamerica, our Mesoamerican scholars are stopped short before its closed portals asking what there is beyond, misunderstanding and baffled by the hints they hear in the verses. The Nahuatl poets, having often penetrated that 'beyond', are on the other hand awestruck by its overwhelming impact on all their senses, on their emotional being, by the certainty they feel that they have here touched base with Truth, by the further question it poses for them about the Absolute and the Ultimate, and by the extraordinary feelings of friendship that it breeds among those who have shared in the common experience. The quality of the singing, the poetry, is enhanced beyond measure by this shared experience, which we in the West have declined to share with them. The poetry, the singing, though they seem to us merely good, take on under the influence of the entheogen the tongues of archangels: both music and verses are of the highest anthropological interest, when understood in the light of the entheogens.

Like almost all of the other top flight Mesoamerican scholars, Father Garibay was ignorant of the wondrous mushrooms and morning-glory seeds. The Nahuatl poems present obscurities and difficulties aplenty, as he makes clear in his commentary. In addition to all the others there is one fabricated by Mesoamerican scholars: Father Garibay fails to realize that *flores* is the trope for the entheogens. They pervade these volumes of verse with obsessional intensity. Here we are for the first time listening in to the aristocrats of pre-Conquest Mesoamerica, without intervention of friars or *conquistadores*, singing the glories of their own entheogens. It proves to be, for us, an amazing experience. Whatever the obscurities and ambiguities of the poetry, one thing seems to me clear: these Princes and Nobles, men of courage and discernment, find on earth little to live for, other than their vistas of Tlalocan made possible by *flowers* and the songs that they composed and sang together. Here there is no ambiguity, no obscurity.

In the following poems, which we have selected from the whole published corpus, Father Garibay's *versión* is on the left, my rendering of his Spanish into English is on the right. These poems reflect the thoughts, the feelings, of the *élite* of the Nahuatl pre-Conquest world. A few words to which I give a different meaning from Father Garibay's are printed in small capitals, and I explain in each case my disagreement. The references in this chapter are to Father Garibay's three volumes of *Poesía Nahuatl* and to the page number.

1. 'Sacerdotes, yo os pregunro: ¿De dónde vienen las flores que embriagan? ¿De dónde vienen las cantos que embriagan?'	'Tell us, O priests, whence come The *flowers* that inebriate? The songs that inebriate?'
'Los bellos cantos sólo vienen De su casa, de dentro del cielo Sólo de su casa vienen las bellas flores.'	'The lovely songs come solely From His house, from within the sky Solely from His house come the lovely *flowers*.'

Poesía Nahuatl 1 p 77

(I interrupt my argument for a moment to call the attention of the reader to a startling circumstance. María Sabina, when repeating the Lord's Prayer in Mazatec, alters the text: 'Our Father Who art *in Thy house* in heaven..', she says, thus interpolating the phrase used in the above Nahuatl poem, also in the poems 3 and 1 quoted below, and frequently elsewhere. I am told this interpolation is frequent among Mazatec speakers and it supplies us with an apt illustration of the cross-linguistic unity known to the cultural student as 'Mesoamerica', Nahuatl and Mazatec being wholly unrelated languages. It speaks for the high antiquity and strength of that cultural entity.)

2. ¿Pero en verdad se vive?
Perecerán las flores que en nuestra mano estaban:
También con ellas se irán embriagando nuestros amigos:
Hemos de perecer en la tierra.

But are we truly alive?
The *flowers* lately in our hands will perish.
Our friends with *flowers* will go on
inebriating themselves:
Our destiny is to perish on the earth.

Poesía Nahuatl 1 p 48

3. Ando en el patio florido,
en el patio florido alzo mi canto.
...
He llegado a su presencia
y hago estremecer ... mis flores embriagadores:
es que alzo mi canto!
...
Llegaron acá nuestros cantos,
llegaron acá nuestras flores...
De dentro del cielo vienen:
allí busco yo mis cantos,
allí busco yo mis flores.
...
De la casa del dios vienen las flores,
en su casa ha de buscarse el canto.

I stroll in the flowery patio,
in the flowery patio I raise my song.
...
I have arrived in your presence,
I wave my inebriating *flowers*,
as I raise my voice in song.
...
Our songs are arrived here,
Our flowers are arrived here...
From within heaven they come;
There is where I seek my songs,
There is where I seek my *flowers*.
...
From the House of God come the *flowers*,
In His house song is to be sought.

Poesía Nahuatl 2 p 34-35

4. Deleitaos con las embriagadores flores
que estan en nuestras manos.
¡Vengan a ponerse en los cuellos
collares de flores:
nuestras flores de tiempo de lluvia:
estén frescas, CUEPONIA
ABRAN SUS CAPULLOS!...
Sólo con nuestras flores démonos placer;
Sólo con nuestros cantos vaya desapareciendo
nuestra tristesa, príncipes:
Con ellas huya vuestro hastío.

Las crea él que hace vivir todo,
Las hace nacer el Arbitro Supremo:
Flores placenteras:
Con ellas huya vuestro hastío.

Take delight
in the inebriating *flowers*
that we hold in our hands.
May they come and encircle our throats,
the garlands of *flowers*!
Our *flowers* of the rainy season,
May they be fresh, may they spring forth!
Only in our *flowers*, let us take delight
Only with our songs, O Princes, may our
sadness vanish.
With them [the *flowers*] may your ennui take
flight!

By Him who makes all live are they created;
The Supreme Arbiter gives them birth.
The joyous *flowers*
With them may your ennui fly away!

Poesía Nahuatl 1 p 50

In these four poems the singers speak to us repeatedly of '*flowers* that inebriate'. The *flowers* are the plant entheogens, the inebriating mushrooms or morning-glory seeds. *Flowers* is a metaphor but 'inebriate' is not. (Father Garibay thought 'inebriate' a metaphor and '*flowers*' just flowers.) Support for my thesis lies in the carvings of the statue of Xochipilli, in the iteration without parallel of *flowers* in the songs of the Nahua, in the word xochi*nanácatl* that Molina gives us for the inebriating mushrooms, and finally in the added muscle and sinew that my interpretation gives to the poems.

Unexpected and telling support for my reading of these poems appeared some years ago in Marino Benzi's book on the rôle of peyote in the culture of the Huichol. The name for the inebriating cactus in Huichol is *jíkuri*, as is well known. But Benzi tells us that in their chants the *jíkuri* is called *totó* and sometimes *rutúri*, both of these words meaning 'flower'. When the Huichol wish to designate the plant to a stranger, they call it by the Spanish word *rosita*, 'the little flower'. In the sixteenth and seventeenth centuries *flor* and *rosa* were used indifferently for 'flower'. (See p 337 in Benzi's *Les derniers adorateurs du peyotl*.)

⋆

The meaning of *cueponi*

In line 7 of our Poem 4 we discover the Nahuatl verb *cueponi* which Father Garibay renders by *abran sus capullos*. The word recurs often in the Nahuatl poetry before us and he almost always renders it by this expression, which in English means 'open their corollas'. I submit that *cueponi* must be translated differently. In Molina's lexicon the first meaning of *cueponi* is to burst forth as a chick from the egg. The second meaning is to burst open as a chestnut when it is roasted. The chick makes its first sounds on this earth as it cracks its shell; the chestnut pops its cuticle as it roasts. This audible effect seems basic to the meaning of *cueponi*. Only the third rendering covers the flowers that emerge from their buds. If my reading of the statue of Xochipilli is right, if *xochinanácatl* means what Molina says it means, if my meaning for 'flowers' is right, then the meaning in the poetry of the Nahua of *cueponi* must often be the bursting forth of the divine mushrooms from the 'egg' that marks their first appearance on earth. And as we all know, at first they do look like eggs, round and white, and they do burst forth overnight. The spirited crackling of the shell as the vigorous chick thrusts its way into the world, the bursting of the chestnuts in the heat of the fire - are not these fitting poetic analogies of the songs, the drum beats, that the divine mushrooms inspire? *Cueponi* occurs so frequently and *cueponi* fits the mushroom world so nicely that it is as if made to order for my argument.

Note that in this last poem the poet links the growth of *flowers* with the rainy season. While of course we know that rain is always associated with the growth of plant life, especially is it so with mushrooms: rains must come before we go on foray to look for mushrooms. In Mesoamerica the Indians await the rains eagerly, knowing that they bring forth the divine mushrooms.

In another poem that Father Garibay gives us (No 5), the second verse, speaking of *flowers*, reads as follows:

Cueponticac xochitl ixpan ipalnemoani

which he translates:

Flowers open their corollas before the Life-giver

But this is obviously a mistake. 'The *flowers* spring forth [like chicks from the egg] before the Life-giver.' The first verse of this poem reads:

Panhuetz panhuetz xochitl

and Father Garibay translates it:

Brotaron las flores, brotaron las flores,

meaning, 'Flowers spring forth, flowers spring forth.' According to Molina, 'panhuetz' means 'to surmount', and the first two lines of this poem should be rendered:

Surmounting, surmounting all *Flowers*
spring forth [like chicks from the egg]
before the Life-giver.

The entheogenic mushrooms, in the poet's mind, surmount everything else in this world. The poem that we are discussing draws a brief note from Father Garibay. He says it is undeniably obscure but that none more merits study. I agree with the latter remark but does not my interpretation clarify the sense?

Here are the verses of this poem to which I would draw the reader's attention. I give Father Garibay's version and then my own:

5. Brotaron las flores, brotaron las flores,
Abren sus corolas ante él que da vida.
...
Ricas olientes flores se van esparciendo,
van al patio enflorado de las mariposas.
Todas allá llegan de donde está La Flor enhiesta:
Flores que trastornan, flores que perturban,
Los humanos corazones de los que se afirman.
Vienen a derramarlas, vienen a esparcirlas,
Cual tejido de flores que embriagan.

Surmounting all, all *flowers* spring forth
like chicks from the egg before the Life-giver.
...
Rich fragrant *flowers* are being strewn,
They go to the patio bedecked with flowery butterflies.
They all arrive from there where *The Flower* stands high:
Flowers that upset, *flowers* that perturb,
Human hearts of those who command.
They come to strew them, come to scatter them,
Even as a web of *flowers* that inebriate.

Poesía Nahuatl 2 p 113

The coming of the *flowers* (= entheogens) is analogous to the birth of life. Raising the voice in song is an offering that serves to express our appreciation of them, our feeling for them. The reader will have observed that in this poem the butterfly figures as in our statue of Xochipilli. This song may have been composed to be sung on the Feast of Xochipilli: it harmonizes well with Diego Durán's description of that amazing annual celebration, which seems to have had as its focus a gigantic effigy of a *flower* raised on high. That effigy could well have been an enormous mushroom made of the stuff of beaten bark, *amate*.

For me, of English ancestry and by deepest cultural inheritance a mycophobe, the divine mushrooms smelled sickening, and on the first occasion I had difficulty in swallowing them. But the Indians, to my surprise, praise smell and taste! Their attitude justifies 'the rich, fragrant *flowers*' of the poem. (Recently I have found some Westerners who also find the taste not bad.)

6. Llegaron las flores:
Que sean ellas gala
Que sean ellas riqueza, Oh príncipes.
Bien nos muestran su faz,
vienen a CUECUEPONTIHUITZ
ABRIR SUS COROLAS
Sólo en primavera alcanzan su perfección,
las innumerables flores,
Llegaron las flores al borde de la montaña.

The *flowers* have arrived:
May they bring joy
May they be our wealth, O Princes!
Well do they show their faces [caps],
They have just burst forth

Only in spring do *they* reach perfection,
The *flowers* without number,
Flowers have arrived on the approaches to the mountain!

Poesía Nahuatl 2 p 131

★

Flowers foster friendship

7. Sólo las flores son nuestra riqueza:
Por medio de ellas nos hacemos amigos
y con el canto nuestra pesadumbre se disipa,
Y en las flores preciosas se ven sus flores en la tierra.
Lo sabe el corazón nuestro.
Cantad como lo quiere el corazón de
aquel por quien vivimos en la tierra.

Only *flowers* are our wealth:
Through them friendship between us grows,
And through song our sadness vanished
And by the *Precious Flowers* we are permitted to see your *flowers* on earth.
We know it in our hearts.
May you sing according to His heart's
desire by Whom we live on earth.

Poesía Nahuatl 1 p 47

The opening lines of this Poem call attention to the effect of the entheogens on friendship: those who share in the entheogenic experience feel tied to each other for evermore by the warmest fraternal bonds. They need never mention to each other the shared experience: each knows it. In Siberia the fly-agaric had the same effect: it allayed animosities, encouraged friendship and understanding. Also in classical sources the annual Mystery of Eleusis gave rise to a bond of friendship among those who had passed that momentous night together. Here is a spontaneous and mighty source for the feeling of *compadrazco*, a Spanish word that I have difficulty in rendering into English.

'Precious Flowers', in the Nahuatl original, is *xochicacahuatl* and this is the name of the tree growing in the state of Oaxaca, in the ancient towns of Huayapan and Zaachila, known to botanists as *Quararibea funebris*, the tree that yields flowers called in Nahuatl *poyomatli*, a flower to which marvelous virtues were attributed, in the first instance having a powerful, lasting fragrance. Its flowers were always mixed with chocolate, a drink that accompanied the ingestion of the sacred mushrooms. These flowers ranked in esteem with the entheogens and seem to have been considered hallucinogenic also. They will be discussed further in the next chapter.

The warmth of fraternal feeling generated by *flowers* is a repeated theme, as illustrated here in this verse:

8. También con flores
allí entonces hay abrazos de unos a otros
Con cantos allí se cargan unos a otros.
Es embelesadora vuestra palabra, Oh príncipes,
se deleitan unos a otros los príncipes.

Also with *flowers* they embrace one another;
With songs they there treat one another.
Your word, O Princes, is enchanting,
The Princes delight in each other.

Poesía Nahuatl 1 p 34

Another poem that Father Garibay calls 'The Tree-in-Flower of Friendship' starts out thus:

9. Ya abre sus corolas el Arbol Florido de la Amistad.

Already burst into bloom the Tree-in-*Flower* of friendship.

Poesía Nahuatl 2 p 5

★

Sights and sounds become one

In my first *veladas* with María Sabina in 1955, I observed that melodies seemed to take on shapes and colors, and sights assumed the modalities of music. Imagine then my surprise when I discovered, in the '60's with the publication of Father Garibay's rendering of the pre-Conquest poems, that these poets had recorded the same phenomena.

10. En estera de flores
pintas tú
tu canto, tu palabra,
Oh príncipe mío, Nezahualcóyotl.

Se va pintando tu corazón
con flores policromas;
pintas tú
tu canto, tu palabra,
Oh príncipe mío, Nezahualcóeyotl.

On a mat of *flowers*
thou paintest
thy song, thy word,
O my Prince, Nezahualcóyotl.

Thy heart is being painted
with polychrome *flowers*;
thou paintest
thy song, thy word,
O my Prince, Nezahualcóyotl.

Poesía Nahuatl 1 p 49

The same theme recurs in this poem:

11. Oh, tú con flores
pintas las cosas,
Dador de la Vida:
con cantos tú las metes en tinte,
las matizas de colores ...
Sólo en tu pintura hemos vivido
aquí en la tierra.

O, thou with *flowers*
paintest things,
Giver of Life:
with songs thou tintest things,
blendest colors ...
Solely in thy paintings have we
lived here on earth!

Poesía Nahuatl 1 p 85

12. Libro de cantos es tu corazón
Has venido a hacer oír tu canto.
Tañendo estás tu atabal
eres cantor,
entre flores de primavera
deleitas a las personas.
Ya estás repartiendo
Flores de fragancia embriagadora,
flores preciosas.
...
Flores ofreces,
variadas flores:
Con ellas deleitas a los hombres
Oh príncipe Nezahualcóyotl.

Your heart is a book of songs;
You have come to let us hear your song.
You are sounding your drum.
You are a singer,
among *flowers* of spring
you delight people.
You are apportioning
Flowers of inebriating fragrance,
precious flowers.
...
You offer *flowers*,
diverse *flowers*:
With them you delight men
O Prince Nezahualcóyotl.

Poesía Nahuatl 1 p 93

'Your heart is a Book of Songs', - the 'book' is *amoxtli*, the codices in picture writing some of which have survived. This is the 'Book' of which María Sabina sings repeatedly, four centuries later and in a tongue utterly different from Nahuatl. Such was the fame of the 'books' of the Nahua and Mixtecs! Father Garibay gives us evidence that this poem was composed almost certainly by Nezahualcóyotl, renowned king of Texcoco.... 'Flowers of inebriating fragrance, precious flowers'. In the Nahuatl text these flowers are the flowers of *Quararibea funebris*: *poyomatli* and *cacahuaxochitl*.

13. Soy cantor y me deleito
Cuando miro las flores y cuando alzo mi canto.
¡Deleitaos con él, Oh príncipes!
De la casa de dios vienen las flores, en
su casa ha de buscarse el canto:
No lo sabían acaso vuestras corazones,
Oh príncipes?

I am a singer and I take delight
When I look on *flowers* and when I raise my song.
Rejoice in my song, O Princes!
From the House of God come the *flowers*,
In His house one must look for song:
Do not your hearts perhaps tell you so,
O Princes?

Poesía Nahuatl 2 p 35

Another Nahuatl poet asks:

14. ¿Acaso de veras viene
desde el cielo florida pintura
en media de las flores?

Is it indeed true that from Heaven
comes the *flowery* painting
in the midst of *flowers*?

Poesía Nahuatl 2 p 88

Surely this poet is recalling in tranquillity his emotions on experiencing an entheogenic *velada* and asking inevitable questions.

And as though answering him another poet sings:

15. De dentro del cielo es de donde vienen
estos bellos cantos, estas bellas flores,
Destruyen nuestra amargura, destruyen nuestra
tristeza.

From innermost Heaven come these lovely
songs, these lovely *flowers*:
They destroy our bitterness, our sadness.

Poesía Nahuatl 2 p 99

Support for the view that *Quararibea funebris* was considered an entheogen is to be found in this poem:

16. Bebamos ahora
Comamos ahora
Cacahuaxochitli.
Con el deleitémonos.
Que ya CUEPUNQUI
SUS COROLAS ABRIERON
tus flores.

Cacahuaxochitla
embriaga mi corazón,
embriaga mi corazón,
Con él ande yo adornado
yo de igual modo también
pueda ir mi corazón.
¡Que no se marchiten las flores!

Poesía Nahuatl 1 p 23

Now let us drink,
Now let us eat
Quararibea funebris:
Let us revel together.

For already thy *flowers* have
burst forth.

Quararibea funebris
inebriates my heart,
inebriates my heart.
May I go about adorned with it,
and also my heart!

May the *flowers*not wither!

In 'A Monologue of Nezahualcóyotl' he exalts the '*flowers* that inebriate':

17. Hay cantos floridos: que se diga yo bebo
flores que embriagan,
ya llegaron las flores [*poyoma*] que
causan vértigo,
ven y serás glorificado.

Poesía Nahuatl 3 p 11

There are songs in *flower*: let it be said
I drink *flowers* that inebriate,
Already came *flowers* causing vertigo.

Come! and you will be in glory

and he continues singing the glory of the blossoms (*poyomatli*) of *Quararibea funebris* that 'color his heart'.

* * *

Anelhuayo: without roots

I now call attention to a stanza that Father Garibay gives us:

18. Vengo presuroso a entretejer
al Arbol Florido
flores rientes.
In Tamoanchan
en alfombra florida
hay flores perfectas
hay 'flores ANELHUAYO
SIN RAICES'

Poesía Nahuatl 1 p 29

I come hastening to interweave
on the Tree-in-*Flower*
laughing *flowers*.
In Tamoanchan
on *flowered* carpets
there are perfect *flowers*,
there are '*flowers* without roots'.

Flowers without roots! What does this mean?

And again:

> 19. Diferentes flores yo estoy esparciendo,
> vengo a ofrendar cantos, *flores*
> embriagantes:
> Soy cara traviesa y vengo de
> allá donde el agua sale;
> vengo a ofrendar cantos, flores
> embriagantes.
> Diferentes flores, aún, aún tu corazón
> lo sabe:
> para tí las traiga, para tí las venga
> yo cargando.
> Vamos a tu casa, vamos,
> traigo como carga
> 'flores ANELHUAYO
> DESARRAIGADAS'
> traigo como carga flores perfumadas:
> Ésta es tu casa: aquí se yergue
> la Flor Blanca.
>
> *Poesía Nahuatl* 3 p 39

> Diverse *flowers* I scatter,
> I come offering songs, inebriating
> *flowers*;
> With mischievous face I come from
> afar where gushes forth the water,
> I come to offer songs, inebriating
> *flowers*.
> Diverse *flowers*, already, already,
> your heart knows,
> May I bring them to you, come loaded
> with them.
> Let us go to your house, come,
>
> I come loaded with '*flowers* without roots',
>
> I come loaded with aromatic *flowers*,
> Here is your home: here stands high the
> *White Flower*.

Again we find 'flowers without roots', *anelhuayo* in Nahuatl!

And a third citation:

> 20. Tu estás enlazado al Arbol Florido
> a las flores que ríen en Tamoanchan:
> sobre estera de flores medran
> aquellas flores,
> y ANELHUAYO
> RAIZ NO CONOCEN.
>
> Garibay, *Hist. Nahuatl Lit*. 1, p 181

> You are enlaced with the Tree-in-*Flower*,
> *flowers* laughing in Tamoanchan:
> On a carpet of *flowers*
> those *flowers* prosper,
> and roots they have not!

In none of these three instances does Father Garibay add a note of comment on 'flowers without roots', an odd expression. For me there is no doubt: we possess here another instance where Early Man perceived the distinctions that mark the mushroomic world. Fungal growths multiply without seed and are without roots. The Mazatec herbalists stressed the seedlessness: in *^{1}nti^{1}xi^{3}tho^{3}*, the formal way of referring to the divine mushrooms, they are saying, 'the dear-little-ones that leap forth', ie come up miraculously, suddenly, without seed. The Nahua, as we see in these poems, emphasized their rootlessness.

Father Garibay explicitly apologizes for the inadequacy of his version of the Nahuatl original of his verses, and now I, *a fortiori*, for my English rendering of Garibay's Spanish. I trust no reader will think that he has been in contact with the Nahuatl poets. But in this chapter I am confident that I have caught and revived an old and major meaning for *xochitl* in the language of the Nahuatl aristocrats, perhaps also (thanks to the distinguished Nahuatlata Thelma Sullivan) come closer to the meaning of the word *cueponi*, and finally given a sense to the word *anelhuayo* in the verses before us. Moreover, when I was first under the influence of the potent mushrooms in *veladas* in the late 1950's, long before I had access to the poetry that we have been discussing, I reported repeatedly the powerful spirit of the ancient agapé that came over us in those gatherings. I also reported how hearing and seeing coalesce. What you are seeing and what you are hearing appear as one: the music assumes harmonious shapes, giving visual form to its harmonies, and what you are seeing takes on the modalities of music - the music of the spheres, is what I then said and published (Harvard *Botanical Museum Leaflet* 19: 7 p 156). Imagine my surprise on finding the Nahuatl poets so impressed by these same phenomena that they felt impelled to dwell on them in their verses.

CHAPTER 5
The inebriating drinks of the Nahua

In *Poesía Nahuatl* 2 there is a poem that begins with this verse as rendered by Father Garibay:

He bebido vino de hongos y llora mi corazón. [page 55]	I have drunk wine of mushrooms and my heart weeps.

This single verse reveals the need for disentangling the words used in Nahuatl and Spanish for the inebriating drinks of Mesoamerica. In Nahuatl it reads:

Oyanoconic in *nanacaoctli*, ya noyol in choca.
I have drunk the liquor of mushrooms and my heart weeps.

Here we find the clue to the full meaning of *octli* in Nahuatl: it was applicable to any inebriating drink, whether alcoholic or entheogenic. In the past *octli* has been taken as the Nahuatl word for any fermented drink, especially *pulque*, the fermented drink of the succulent *maguey*, but *nanacaoctli* is also clearly the [inebriating] liquor of [entheogenic] mushrooms: *nanaca*- from *nanácatl*, 'mushroom', and -*octli*, 'liquor'. For centuries we have simply ignored the entheogens.

When Cortés and his men mingled with the Aztecs in the Valley of Mexico, they found themselves before a complex of strange inebriating drinks for which they had no Spanish names. The common drink was the fermented sap of a succulent (not a cactus) classified by botanists as a species of Agave, made according to complicated steps elaborated through millennia of cultivation. The plant today is known in Spanish as *maguey*, a word introduced into Mesoamerica by the Spaniards from Taíno, a language of the Antilles. (The specific name in Nahuatl is *metl*.) This drink is familiar to us as *pulque* but where *pulque* comes from no one knows for certain. It is not a Nahuatl word. The earliest citation for it is in a letter that Cortés addressed to his Emperor Charles V dated 15 October 1524, a date so early that it precludes a borrowing from any South American Indian language. An ingenious suggestion is that it was a deformation on the rude tongues of the Spanish soldiery of Nahuatl *puliuhki* meaning 'perish', 'gone to waste', a pejorative characterization of the native drink. Pulque is fit (and excellent) for human consumption for only a little more than 24 hours, whereupon it does degenerate into a decomposed, rotten, stinking fluid. We may assume that this is probably the origin of pulque until a better explanation presents itself.

The Nahua called pulque *octli*, but as we have seen this was the name given to inebriating drinks in general, of which there were many, alcoholic and entheogenic. Father Garibay followed the practice of the Spanish friars in translating *nanacaoctli* by *vino de hongos*, 'mushroom wine', a grave mistake for it plants in the mind of the uninformed that the mushrooms were either alcoholic or bore an analogy to fermented grape juice. For the Spanish soldiery wine was the common inebriating drink, beer and brandy hardly being known in Spain in the early 1500's and not known at all in the New World, and naturally the friars with their poor vocabulary for inebriating drinks and their non-existent experience with the mushrooms resorted to 'wine' for the entheogenic mushroom juice. But it is surely time that we do better.

Father Garibay did not enter into the intricacies of Nahuatl drinks, which were alien and confusing for him. It seems to me certain that the *flowers* (*xochitl*) of the Nahua were used for what we would call today the entheogens, and furthermore limited to those entheogens considered fit for the aristocrats. Father Garibay says that a plebeian who drank chocolate (with *flowers*?) exposed himself even to the penalty of death.[19] He does not cite his authority for this and neither I nor my acquaintance among Mesoamerican scholars can supply it. The Nahua paid high honors to pulque in certain religious celebrations but by comparison with -*xochi*- potions it was a vulgar beverage, easily accessible to anyone and a source of much drunkenness. The -*xochi*- beverages were not drunk by the *élite* at the same time as pulque. Father Garibay says that the *flowers* were drunk with pulque or alone, but in the four volumes of poems that he has given us only two seem to mix *flowers* with pulque, and those two serve but to prove my rule, for they are expressly composed (though by

---

19. Garibay [4] 1 p 109.

Nahuatl poets) in the Huastecan and Chichimecan manner.[20] These peoples were considered barbarians by the Aztecs, possibly admired in some contexts in a condescending way but with a reputation for wild drinking habits. Our two poems, then, even in the Spanish rendering, reflect this change of pace and tone well, especially when a vulgar woman of low degree, a Huasteca, declares herself drunk on a mixture seemingly of *flowers* and pulque. (Her part was probably played by a Nahuatl man dressed to fit the rôle.) The incessant reiteration of *xochitl* and *-xochi-* in this body of poetry astonishes the reader today, mostly in a context of drinks, but in the elegant poetry of the Princes and Nobles there is never an instance where pulque is linked to *flowers*.

The anthologies that are represented in Father Garibay's volumes serve us admirably in conveying the poetic voices of the *élite* of the Nahuatl world. The collections were assembled for us by leading survivors of the defeated race and these survivors must have enlisted the cooperation of many eager to contribute the poems that they had memorized to those who had succeeded in learning our alphabet and who could write them down. What pathos! With their world laid waste, their own exalted position in it destroyed, yet their precious heritage of verse, esteemed by them above all else, was put down on paper for someone, somewhere, sometime, somehow to decipher (and with what labor!) and then for this shadowy audience to enter into their magic world and relive what they had experienced and thought. What likelihood did they think there was that these verses in Nahuatl would be read? Yet today we can listen to the poets of this extinct world in proto-history speaking and singing to each other. What we hear is surprising: awe and wonder at what the *flowers* disclosed to them, the excitement and delirium of their 'wars', and the somber shadow of human sacrifice against which there is no whiff of opposition though the poets themselves were sometimes destined to be its victims. There is even a poem composed probably by a captive already awaiting the obsidian knife.[21]

We have the best of outside evidence that alcohol was not mixed with the entheogens in the festivities of the upper caste of the Aztecs and others in the Valley of Mexico and thereabouts. Diego Durán, the chronicler who relied heavily on the now lost *Crónica X* written in Nahuatl by someone who moved in the highest circles in pre-Conquest times, is giving us a detailed account of the coronation of Ahuitzotl ca AD 1486 and then Durán adds:[22]

> In this whole story I have noted one thing: mention is never made that anyone drank wine of any kind to get drunk, but only woodland mushrooms, which they ate raw, on which, says the History [*ie Crónica X*], they were happy and rejoiced and went somewhat out of their heads, and of wine no mention is ever made, unless for sacrifices or funerals; mention is only made of the abundance of chocolate that was being drunk in these solemnities.

When Durán here speaks of 'wine', he means alcoholic beverages such as pulque, and the chocolate was taken with *flowers*. This quotation will be further discussed later, p 201 [of orig. vers.].

In our own explorations through Mesoamerica we found repeatedly that alcohol was expressly forbidden to those who were ingesting the sacred mushrooms. The duration of this alcoholic abstinence varied: for one day before, or two, or three, or most often four. These were norms; I do not say they were always observed. And María Sabina always looked to her host at her *veladas* to supply *un cuartito* of *aguardiente* (a half pint of alcohol) for her to drink when her strenuous night's work was drawing to a close. (This was obviously a post-Conquest innovation.) In Mesoamerica there were two categories of inebriation, divine inebriation from the superior entheogens (*ie* mushrooms or morning-glory seeds) and alcoholic inebriation from pulque and the like.

The whole world today knows the cactus *Lophophora williamsii* as *peyote*, or in standard Nahuatl as *peyotl*, the whole world except the Indian peoples (Huichol and Tarahumara) in whose religious life it figures large and who have their own names for it. But I raise the question whether the meaning of *peyotl* in Nahuatl was confined to the cactus *Lophophora williamsii* in pre-Conquest days. This word circulates throughout much of Mesoamerica in regions where the importation of the cactus from the far arid north seems highly improbable.

---

20. Garibay [4] 3 pp 28, 32.
21. Garibay [4] 2 p CXXVIII (30).
22. Garibay [5] 2 p 236 § 16.

It takes various shapes as it passes from one linguistic area to another. Aguirre Beltran documents it in the Proceedings of the Inquisition in these forms: *peotl*, *piot*, *piyolli*, *peyori*, *peiot*, and above all *piule*. There is no reason to think that the meaning of these words is confined to the cactus. In our own day the lexicographer Santamaría says that *piule* is used in Oaxaca for the entheogenic morning-glories. Richard Evans Schultes found it thirty years ago applied to entheogenic Rhynchosia seeds in the market place of Villa Alta, in Zapotec country, and also in the market of the city of Oaxaca. In 1955 Robert J. Weitlaner and I were in San Agustín Loxicha, in the Sierra Castera south of Miahuatlan, and we found that *piule* was applied here by the *sabio* don Aristeo Matías to two species of entheogenic mushrooms and also that it figured in the powerful myth linking the origin of the mushrooms to thunderbolts. May not *piule*, derived as it is from *peyotl* in pre-Conquest times, have been used for any entheogen in the vulgar language, called *macehuallatolli*, and then have spread far and wide, being deformed on alien tongues as it crossed linguistic frontiers?

But if *peyotl* was any entheogen, why do we never find it in the four volumes of verse that Father Garibay has given us in Nahuatl? Perhaps the answer lies here: the Nahua of the highest social class spoke their language in an elegant manner known as *tecpillatolli*. Was it not this manner of speaking that our poets were giving us? And for them in *tecpillatolli* the entheogens (or the superior entheogens) were as we have seen *flowers*. *Peyotl* or *piule* was left to the masses, whence they were borrowed by the linguistic groups of Oaxaca and perhaps beyond.[23]

The Nahuatl poetry available to us is filled with entheogenic drinks. One verbal element is common to all of them: -*xochi*-, the various drinks in the -*xochi*-cycle having effects on the human psyche that are indistinguishable. The other verbal elements linked to -*xochi*- are *teo*-, 'divine' or 'wondrous', *octli*, any inebriating drink, and the word for water, *atl*, often reduced to *at* or its root *a*. To this day on the slopes of Popocatepetl the divine mushrooms are called in Nahuatl the 'little children of the waters', *a-pipil-tzin*, *a*- for 'water', -*pipil*- for 'children', and -*tzin*, a diminutive of endearment and respect.

Are not the drinks to which water is linked the ones made from the sacred mushrooms? Only those who, like the Russians, are brought up to love and crave mushrooms, the mycophilic peoples, know the meaning of rain for their adored mushrooms. In Russia there is a special rain, - 'mushroom rain', *gribnoi dozhd*' - that everyone knows is specially favorable to mushrooms. And *a fortiori*, raised to the nth power, is the joy in mushroom rain of a folk who know and make use of their own entheogenic mushrooms. A rain peopling the land with the divine mushrooms, the little-children-of-the-waters, is a gift that only a god can give.

Here then in Father Garibay's four volumes in Nahuatl verse are the words for inebriating drinks of which many specifically mention, if we are right, the entheogenic mushroom *flowers*.

Poesía Nahuatl 3 (No. of poem and line)		
13.92, 99; 14,21	*xochi*-octla	entheogenic potion
8.9; 14.7	*xochi*-octli	entheogenic potion (not 'pulque' as Father Garibay renders it in 8.9)
2.26; 5.7; 14.99; 23-I.8	*xochi*-atl	wondrous mushroom potion

13.87	teo-a-*xochi*-octli	wondrous mushroom potion
13.11	teo-a-*xoch*-octla	wondrous mushroom potion

---

[23] After writing this I came upon R. E. Schultes' *Harvard Botanical Museum Leaflet* Vol 5 No 5, 19 Nov 1937 wherein he informs us that B. P. Reko had reached conclusions parallel to mine about the pre-Conquest meaning of *peyotl*. Reko made chis discovery a half century ago. *El México Antiguo* Vol 3 Nos 3/4 Dec 1934: 'Das Mexicanische Rauschgift Ololiuqui' pp 1-7; also Schultes, Harvard *Botanical Museum Leaflet* Vol 4 No 8 12 April 1937.

13.37	teo-atl	divine water (mushroom potion?)
Poesía Nahuatl 2, 1st sec.		
13.37	cacahua-octli	chocolate with flower petals and entheogens

★

But the question remains how it came about that *xochitl* acquired its unique status as the symbol of the divine draught among the Princes and Nobles of the Nahua. The evidence for this status in the carvings on the statue of Xochipilli, in the name *xochinanácatl* for the sacred mushroom that Molina gives us, in the poetry of the upper caste of Nahua, where the theme of the '*flowers* that inebriate' is insistent, is I think conclusive: the *flowers* enjoyed exalted, even divine status and lent themselves to a further level of metaphorical use when they served for the 'wars' or raids for sacrificial captives, a constant activity of these Indian peoples, for their war gear, and for the captives themselves.

Up to now we have not mentioned *xochitl* in a verbal combination that occurs more frequently than any other: *cacahua-xochitl* or occasionally *xochitl-cacahuatl*. *Cacahuatl* is none other than the chocolate or cacao tree, the *Theobroma cacao* L. of botanists. (Linnaeus gave the name 'Theobroma', the 'food of the gods', to the cacao tree allegedly because of the esteem in which it was held by the Indians.) Chocolate was drunk cold and mixed with aromatic flower petals of which the overwhelming favorite was *cacahua-xochitl*. Indeed it seems as though these particular petals were indispensable. Our poets' 'chocolate flowers' had nothing to do botanically with *Theobroma cacao*, but everything to do with the chocolate beverage as drunk by the aristocrats, according to Father Garibay. If he is right, we find here additional underpinning for my belief that the *flowers* of the Nahuatl poets come from their exclusive privilege for indulging in the flower petals of the *cacahua-xochitl*. Here we are dealing with a tree that grows in Veracruz and Oaxaca, known today to botanists as *Quararibea funebris*. Whether the petals of these flowers were entheogens such as the mushroom and morning-glory seeds, I do not know, but that the lords of Nahua so regarded them seems virtually certain. That these mushrooms or the *ololiuhqui* seeds (ground to fine powder on the *metate*) were often or perhaps always drunk with the cacao potion is also certain: when they are not mentioned, the poets may well have taken them for granted. After all, the poets were writing for each other, certainly not to inform us. Sometimes we read that the mushrooms were *eaten* but then mention is usually made of the chocolate-flower beverage accompanying the mushrooms. In glowing terms the poets speak of this chocolate drink as an excitant, an aphrodisiac, possibly an entheogen. It inspired them to compose their poetry and music, to dance, to sing. So far as the evidence goes, we should not think of these celebrations as riotous drinking parties: they were suffused throughout with religious feeling and with the melancholy that, soon or late, attends man's thinking here below. The poems bear witness to this.

There comes down to us in the writings of the friars the name of a mysterious vegetable product, *poyomatli*, but they never identify it. Everything concerning *poyomatli* written by the friars is enigmatic, tantalizing, mysterious. Did they not deliberately conceal its identity, feeling it was best for them to hide from the laity a product of such enticing potency?

Yet already in 1963 its identity was accessible to us: Dibble and Anderson, slowly and carefully progressing in the difficult translation of the Nahuatl text of the celebrated *Florentine Codex*, came at last to the description of the tree called *cacahuaxochitl* (our *Q. funebris*) and here is our answer:

> [This tree] has cup-like [blossoms]; the name of its cup-like [blossoms] is *poyomatli*; a really pleasing odor is their aroma. The tree, the blossoms, its foliage, all are of pleasing odor, all perfumed, all aromatic. I cut [the blossoms], spread them out, arrange them, cover them with leaves, thread them, make a flower mat of them, make a bed of flowers with them, spread them over the land. [The perfume] spreads over the whole land, swirls, constantly swirls, spreads constantly swirling, spreads billowing.
> [Bk 11, *Earthly Things*, p 202]

And so to the long list of references to *cacahua-xochitl* we must now add all *poyomatli* citations!

Ten pages later Sahagún's Nahuatl informant dictated this additional comment on *poyoma-xochitl*:

> This is the cup of *cacahua-xochitl*. They say it makes one falter, it deranges one, provokes one. It makes one falter, it deranges one, it provokes one.
> [*ibid*, p 212]

'*They say*...'! Who are '*they*'?

Let us pause a moment and examine that brief, innocent-looking phrase.

On the heels of the Conquest, Bernardino de Sahagún, the Franciscan friar, spent his entire adult life, about half a century, studying the Nahuatl-speaking Indians. He chose his informants carefully for their maturity, their experience, their character and knowledge. The *Florentine Codex* and the priceless manuscripts in Madrid are an invaluable treasury, in Nahuatl and Spanish, concerning the history, the customs and manners, of the Nahua, assembled under Sahagún's editorial supervision. Many other friars concerned themselves with writing about the Mexican Indians but Sahagún and Diego Durán are outstanding in the extent and thoroughness of their work and in their underlying sympathy for the people they were studying. The Spanish text has long been avail able to scholars but the Nahuatl text giving the very words taken down from the lips of the informants has just in recent decades gradually become accessible to Western scholars. The Nahuatl texts must be read in the light of the circumstances under which they were written down. There were subjects that no sixteenth century friar, not even Sahagún, could tolerate and one of them was the entheogens. Knowing nothing personally about *poyomatli* (nor about the entheogens), the friars had damned it (and them) sight unseen: the entheogens meant trafficking with Satan. We are grateful to the churchmen for what they tell us about these plant products but we must be on our guard. The Nahuatl texts of the informants sometimes give us a clue to what they were really thinking. Take for instance what one informant said about *poyoma-xochitl*: '*They* say it makes one falter, it deranges one, provokes one'.

The informant had doubtless accepted the Christian faith. An intelligent, well-informed Indian, he held a position that was enviable, one who was serving Sahagún and his team. There can be no doubt that he had known the entheogens personally or at least the reputation that they enjoyed among his people. He was testifying on a delicate subject. He knew that the friars looked to him for an unfavorable characterization of *poyomatli*, but in complying with their wishes he succeeded in slipping in, '*They say*...'. Who are '*they*'? Certainly not informed Indians: they would have answered in line with the exalted tone of the Nahuatl songs that we have reviewed. Was not the informant escaping responsibility by quoting the friars? Confronted with a dilemma, he was deftly showing his regard for the truth by an attribution of his statement to his ecclesiastical mentors.

Here in this text, as elsewhere, we feel the pressure that the informants were under, when discussing sensitive topics, to comply with the prejudices of their interrogators. I do not mean that they were in fear of harsh legal sanctions but as informants of Sahagún they enjoyed a privileged status in the Nahuatl community that they would fain keep. Our Nahuatl poems, written by free and intelligent men before the Conquest, suggest no 'faltering', no 'derangement', no 'provocation'. Their praise of this tree and its flowers knows no limit. The only 'derangement' would be analogous to the derangement of a Saint in ecstasy. In this passage our informant managed to reconcile what he knew with what he was supposed to say. In the earlier quotation the concluding lines convey eloquently the praise of *cacahua-xochitl* blossoms that expressed what all Indians felt: the perfume of these flowers 'spreads over the whole land, swirls, constantly swirls, spreads constantly swirling, spreads billowing'.

Here then are the *poyomatli* citations that I have caught in the four volumes of Nahuatl verse given to us by Father Garibay:

Poesía Nahuatl 1 (No. of poem and line)		
1.20	xochi-*poyon*:cuica	
1.21	*poyon*-cuica	
56.31	*puyuma*-xochitli	
Poesía Nahuatl 2, 1° sección		
8.27	*poyoma* in ye nochicuacol	
17.6	*poyoma*-xochiuh	
23.33	in-*poyon*	(Tamoanchan)
Poesía Nahuatl 2, 2° sección		
14.5	*poyon*	(cacahua-xochin-poyon)
14.24	*poyon*	(quetzalin-poyon)
Poesía Nahuatl 2, 3° sección		
13.3	xochin *poyon poyon*	
21.16	xochi-*poyon*	
Poesía Nahuatl 3		
1 iii.28	in ahuiyac *poyomatli* in pixahuia	
4.35	ye nican *poyoma*	
4.42	in-quetzal-*poyomatl*	
9.19	*poyoma*-xochitl	
12.44	in-quetzal-*poyoma*-xochitl	
Veinte Himnos Sacros		
p 117	*po[yo]ma*	(Father Garibay's reading, p 121)

In the writings of the Conquistadores - as distinct from the friars and priests - I know of only one reference to the entheogens, a glancing inadequate observation in Bernal Díaz de Castillo's memoirs. Speaking of Montezuma he wrote:

> Traían en unas como a manera de copas de oro fino con cierta bebida hecha del mismo cacao; decían que era para tener acceso con mujeres, y entonces no mirábamos en ello.
> [Chap xci]
>
> They would bring in to Montezuma something after the style of cups of fine gold with a certain drink made from the same cacao; they would say it was to have access to women, and so we did not inquire further.

Here is the chocolate beverage surely spiked with *poyomatli* and perhaps other superior hallucinogens. But Bernal Díaz says no more.

The poetry of the Nahua aristocrats supports with overwhelming evidence the hold on their imaginative life of *Quararibea funebris* and its flower *poyomatli*: I suggest that therein lies the origin of the metaphorical use of *xochitl* ('flower', *flor*) for the hallucinogens and for the dominance of '*flower*' in the poetry of the Nahua. This dazzling yellow flower swirls, constantly swirls, spreads constantly swirling, spreads billowing over the whole land.

★

Father Garibay was helpless before the inebriants of the Nahua. He called *xochioctli* 'pulque'. (*Poesía Nahuatl 3* 17.9) He described *poyomatli* as a 'stupefier', again as a root, again as a 'species of *peyotl*', all in one breath. (*Poesía Nahuatl 3*, p xxv) He said in 1967 that *ololiuhqui*, the entheogenic morning-glory, was a 'stupefier' and probably a Datura (*Poesía Nahuatl 1*, p 226), though its identity had been established with finality by Richard Evans Schultes as long ago as 1941. He translated *poyomatli* as a '*narcotic* of flowers' (*Poesía Nahuatl 3*, pp 11, 19), as '*lethargy* producing' (*Poesía Nahuatl 1*, p 1), as '*enervating*' (*Poesía Nahuatl 3*, p 5). He thinks that the poets with all their talk of the entheogens were engaging in metaphorical wordplay! At least he says so in his commentary. He never tells us where they gained their experience of those other worlds of Tamoanchan and Tlalocan.

True, in the past many have called drugs with mental effects by terms such as these without discrimination. But plants that inspired an outpouring of extraordinary poetry, of music, of dancing, are hardly stupefiers, narcosis-producing, enervating, or lethargy-producing. It is time that we learn to characterize our mental states with feeling for the words we use, and also that the Nahuatlatos learn to talk with living botanists, rather than rely on obsolete botanical sources.

But let me hasten to add that we all and I in particular owe an immeasurable debt to Father Garibay. He marked an *étape* in Nahuatl studies that will never be forgotten. He has triggered a new interest in pre-Conquest Nahuatl culture that promises to illuminate a field of proto-history of incalculable cultural importance. These chapters of my book obviously could not have been written had he not provided the Nahuatl text of the poems I discuss.

Furthermore, Father Garibay's unfamiliarity with the inebriants of the Mesoamerican Indians in no way differentiates him from scholars past or present in this field of inquiry. If he shows up worse than others, it is only because he had the courage to confront texts that deal directly with the entheogens.

Now it is urgent that the entire corpus of Nahuatl poetry, most of it pre-Conquest, be transcribed and published, and that it be rendered into a modern language, presumably Spanish, not in verse but in a scholarly translation. Father Garibay has whetted our appetite: we wish to listen to the pre-Conquest Aztecs speaking freely with each other, without the intervention of even the best of the friars. The number of our Nahuatlatos is slowly increasing, and the ideal would be to find the one who combines in himself (or herself) the severe discipline of an exegete and the afflatus of the poet.

⋆

In the earlier chapters I have given a picture of the shamanic use of the entheogenic mushrooms in Mesoamerica as it survives into our own times. How widespread was this shamanic use? In Mazatlán de los Mixes we discovered that a shaman was not needed for consulting the mushrooms: there was a lay use of them. Anyone facing a grave problem would consult them, or perhaps a friend on his behalf and in his presence, also with a monitor, and then the mushroom would converse audibly with the eater and the monitor would make mental note of what was said. This might be regarded as a degeneration of an earlier shamanic practice, but Mazatlán de los Mixes is secluded, far from the beaten track, and may not their ways be rather an archaic survival in the Indian world?

An essential of shamanism is conformity, in the flow of words from the shaman's lips, in the music of his chants, in the percussive beats that accompany the singing. In each performance the shaman is limited in the deviations that he may introduce by the circumstances of the particular consultation that he is giving. He invokes a ritual whose authority lies in its antiquity and its universality, and the vocation of a shaman is essentially anonymous. True, in a given generation such-and-such a shaman is said to be of *primera categoría*, 'top category', but this is simply because he performs better than others a fairly rigid procedural canon, not because of innovations in that procedure, and when he is gone his memory lingers only for a few years among those who were his contemporaries.

Now let us contrast our shamanic *veladas* with the Nahuatl poems that Father Garibay has enabled us to examine. These are as far removed as can be from the chants of María Sabina, the unlettered shaman of the Sierra Mazateca. They are poems written in the decades that preceded the Conquest by the Princes and Nobles in the cities in and around the lakes of the Valley of Mexico. Each poem is an individual's studied composition. In some cases the poets are known: their names, when they lived, and some of the circumstances of their lives. Their poems are sophisticated literary productions of individual poets, and the *élite* of the Nahuatl world were immensely proud of them. Many, perhaps all, of them were recited or sung at gatherings of the poets around the *Xochicuahuitl*, the *Arbol Florido*, the Tree-in-*Flower*. This was an idealized tree, set up *ad hoc* for such festivities. If Peter Furst is right, it was an ancient institution and we find it represented in a painting at Teotihuacán, which Villagra Caleti has reproduced for all to see in the Museo Nacional de Antropología. Furst goes further: he argues that it is a highly stylized morning-glory (*ololiuhqui*) 'tree' and as I have said I think he is partly right.

The question is how to reconcile, on the one hand, the *veladas* held by shamans throughout Mesoamerica for millennia, in the dead of night, to help all kinds of humble suppliants facing life's problems, and on the other the festive open-air performances with music, dancing, singing, and poetry readings by the self-assured princes and aristocrats around the Tree-in-*Flower* and on other grand occasions, these performances going back, back beyond memory, if our interpretation of the Tepantitla 'Tree-in-*Flower*' is right. Both were inspired by *flowers*. In sophistication they were at opposite ends of the spectrum: would not the teeth of the aristocrats have been set on edge by the shamanic chants, so self-conscious were their highly spontaneous verses? Individual poets achieved fame for their excellence but in a culture where there was no way other than human memory to preserve the words of a poem, the fame of even the best poets was not likely to endure for more than a few decades. Is there any reason why the Tree-in-*Flower* could not have been celebrated every year, perhaps in every important community, from the days of Teotihuacán and long before, down to the Conquest? Social institutions and customs evolved slowly before easy writing came to mankind.

María Sabina and the poets of the two sixteenth century Nahuatl anthologies express the same profound reverence for the 'Book', *amoxtli*, by which the poets meant the superbly painted picture-writing codices, kept beyond the reach of the masses in the *Amoxcalli*, the House of the Books, the Holy of Holies. And what that reverence must have been! It survived in María Sabina's chants into the late twentieth century, though for her it is become a purely mystical book, as it may well have been for her predecessors. For when a provincial shaman, even one of exceptional quality, visited Tenochtitlan, what access had that shaman to see and examine the Treasures of the *Amoxcalli*?

CHAPTER 6
Códices, lienzos, mapas

Codex Vindobonensis

The documentary sources for the pre-Conquest history of Mesoamerica include a considerable number of what are called in Spanish *códices*, texts painted in picture-writing that are being progressively deciphered by scholars dedicated to that task: they do not lend themselves to easy and assured reading. They were painted by priests of the Old Religion and were originally accessible only to the priesthood, but their renown was breathtaking. It seems to have run far and wide throughout Mesoamerica and we find the shaman María Sabina even today singing (and in Mazatec!) of the *Libro* with its numinous message, by which scholars seem agreed that she means, transmuted through more than four centuries of oral tradition, what were called by the Nahua *amoxtli* and by us in English the painted codices of pre-Conquest times. The memory lingers on, severed from its roots, having had no contact for almost half a millennium with the documentary sources that originally inspired it.

We had refrained from tackling these codices in our quest of mushrooms partly because our hands were full with other sources easily accessible to us but chiefly from a feeling of inadequacy. What then was our surprise and delight when Dr Alfonso Caso, dean of Mesoamerican scholars, published a paper in the 1963 number of *Estudios de Cultura Nahuatl*, Vol IV, revealing our entheogenic mushrooms on a page of the celebrated *Codex Vindobonensis*, the 'Vienna Codex'. This Codex was painted, not in a Nahuatl but in a Mixtec scriptorium, and it gives the mythological Origin of Things. (Fig 1) Our interest is in the origin of the entheogenic mushrooms. The reader enters p 24 at the lower right hand and reads upwards in the right-hand column until, reaching the top, the mushroom agapé of the gods fills both columns.

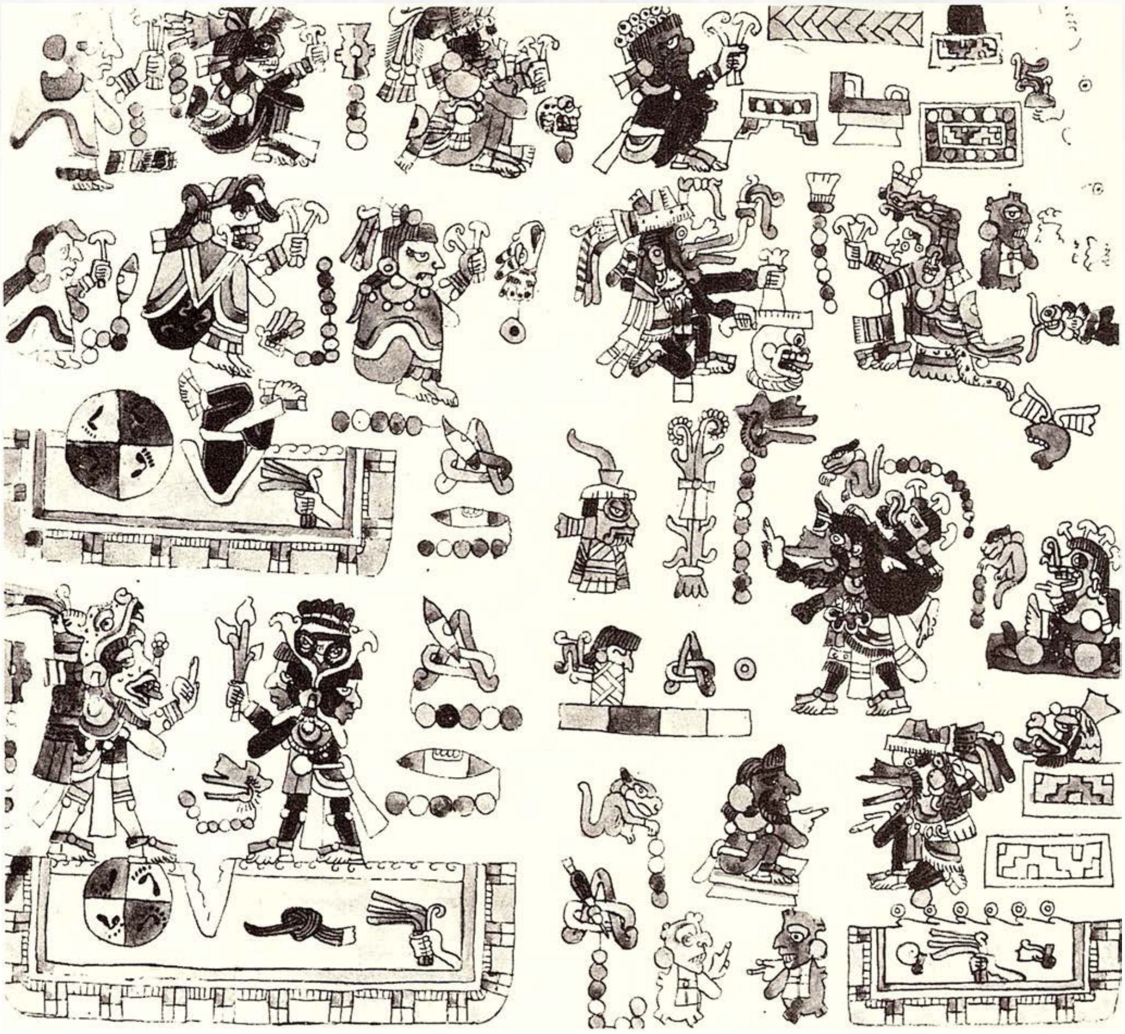

Fig 1 *Codex Vindobonensis*, p 24

Abbreviating the story, we find near the bottom the god Quetzalcóatl in full panoply and wearing a mask with a bird's beak. He is listening respectfully to an aged god who is, it seems, giving him instructions. On the next level up and to the right a woman in a mask sits next to two burning incense (*copal*) balls. She is the incarnation of the spirit of the mushrooms and she wears four mushrooms in her hair. To the left we find Quetzalcóatl carrying this woman on his back after the manner of a bridegroom carrying his bride. Her headdress still carries mushrooms. On the level above, Quetzalcóatl, now facing to the right, is singing and beating time on a sinister musical instrument, a skull resting on a corded ring. He faces Piltzintecuhtli, 'Most Noble Prince', securely identified by his calendar sign Seven Flower, and this divinity is now holding aloft a pair of mushrooms. From his eye falls a tear, in response to the song of Quetzalcóatl. Let the reader note that Piltzintecuhtli is an aspect of Xochipilli, Sun God, the Prince of *Flowers*. We shall return to Piltzintecuhtli in Chap 7. Above and to the left of this scene we see seven gods and goddesses all bearing in their raised left hands a pair of mushrooms that (presumably) they are about to ingest. (There is one exception: a crone at the extreme left in the second row holds, strangely, only one mushroom. The second divinity on the top level also seems to hold but one: however, in the codex itself the figure is seriously eroded and we cannot say what she holds.) I take it this scene is not a banquet but a *velada*, the religious rite held at night.

There can be no question: in this Mesoamerican document we find full dress recognition of the major place occupied by mushrooms in the culture of the Mixtecs; in what we, being alien to that culture, would call their mythology but what the Mixtecs would have regarded as a feature in the story of their origins. W. Lehmann published a commentary in 1929 on this codex and he remarked on the 'objects in the shape of mushrooms', but as he (as well as everyone else at that late date) was living in ignorance of the rôle of mushrooms in Mesoamerican culture, he did not link this lordly scene with the mushrooms of the friar chroniclers.

(Since I wrote the foregoing paragraphs Mr Frank Lipp, associated with the New York Botanical Garden, has called my attention to another Mixtec pictogram in the *Lienzo de Zacatepec* No I, which lies today in the Museo Nacional de Antropología. It repeats the message of the woman bearing mushrooms in her hair, except that here the head is a man's. The head rests on top of *cerro* (hill). May it not represent a sacred mountain on the summit of which *sabios* or wisemen were accustomed to celebrate the mushroom agapé?)

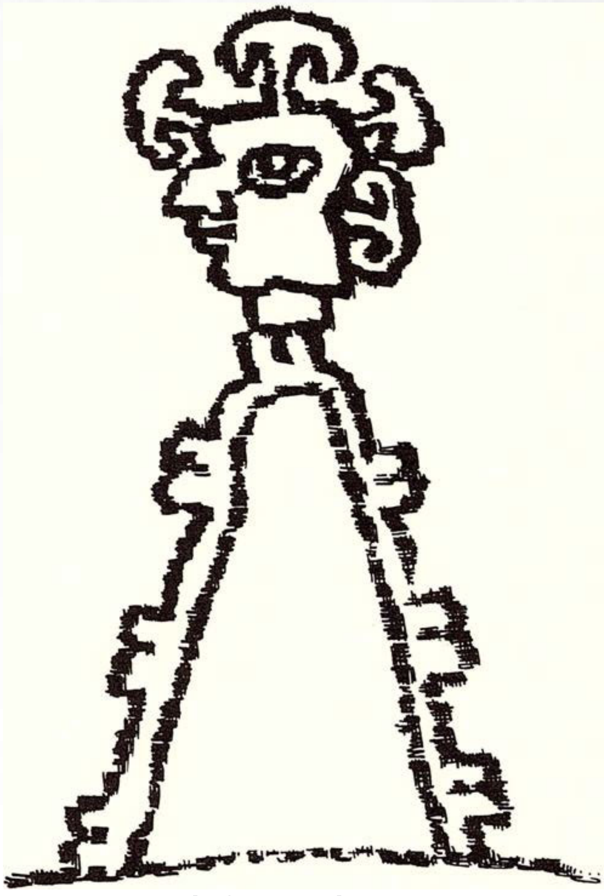

Fig 2 Detail of *Lienzo de Zacatepec* No I

In the opening paragraph of his paper Dr Caso recognized his indebtedness to Roger Heim and us for calling attention to the entheogenic fungi. He even specifies our reproduction of five Teotihuacán murals and endorses our identification of mushrooms in them. This was a gratifying accolade, all the more so because of his authority. But I would point out that there are in his paper marked traces of the legacy of the sixteenth century Spanish friars. Our writings (Heim's and the Wassons')

> ... han dado a conocer ampliamente este aspecto de la hechicería que se ha conservado en algunas panes del país...
>
> ... have amply made known this aspect of the witchcraft that has been retained in some parts of the country...

'*Amply made known*'! He seems to have thought that we had exhausted our theme in what we had already published. But we had only opened up a vast subject, not merely in the Indian world of Mesoamerica but in the Americas and Eurasia, and perhaps elsewhere. He did not sense the implications of the entheogens in Early Man's life. Dr Caso treats our mushrooms gingerly. With the tips of his fingers, he advances his interpretation of the mushroom scene in the Codex tentatively: it is an 'hypothesis', it 'may be' right, although he has copper-riveted his proofs as we shall see shortly. He echoes the friars when he expresses his antipathy to the realm that he denominates by the pejorative, question-begging epithet 'witchcraft' and when he speaks of the mushrooms as *esta práctica mágica*, 'this magical practice'. Only in recent decades have scholars made serious inquiries into the peculiar 'witchcraft' phenomena of the late Middle Ages and Renaissance, and the panic that they provoked in the Churches, Catholic and in the later stages Protestant.[24] There was no witch-hunting in Eastern Orthodoxy.

Let us pause a moment and develop this thought. For some centuries there had been in Western Europe a polarization between the Established Church on the one hand and an amorphous body of 'witches', whose beliefs such as they were had nothing in common with native Mesoamerican beliefs. The Spaniards brought over to the New World the religious beliefs held in Western Europe, including Catholicism and *brujería*: both were equally strange to the natives and, as coming with the Spanish Conquerors, enjoying equal prestige. By grafting on to the unknowing Indians the old-world *brujería* and later reproaching the Indians for entertaining it, are we not supplying a supreme example, a textbook case, of anatopism, an error in space corresponding to an anachronism in time? What of witchcraft or magic is to be found in entheogenic mushrooms? In psilocybin? (The 'witchcraft' of the time had nothing to do, of course, with the heresies that preoccupied some of the best minds of the age in Western Europe and that culminated in the Reformation.)

The clergy treated alcoholic inebriation as a venial sin. It was condemned severely by the Nahua in pre-Conquest times, when pulque was expressly reserved for the oldsters who had passed their period of usefulness and were awaiting their end. (Of course the official attitude may not have reflected the practice: prohibition was probably a failure with them as with us.) Inebriation from mushrooms and certain other hallucinogens, on the other hand, was confused by the clergy, not with alcoholism, but with *brujería* and heresy.

As for the pre-Conquest codices, I looked at them and could not read them, but I was approaching them from a new perspective, the perspective of one who knew the entheogens from many years back. The variegated colors, the play of angles and curves, the interlacing of planes, the reduced figures, the complicated masks and vestures - these all seemed somehow familiar to me. It came over me gradually: the dancing kaleidoscopic designs of the mushroomic experiences were what inspired the painter of the *amoxtli*. Henri Michaux and many others have attempted to find artistic inspiration in entheogenic drugs, but to discover an art that was saturated with their influence and at the same time under the disciplined control of masters with a lifetime of entheogenic experience, we must look to pre-Conquest codices. Here is no fumbling of the novice. Many have been awestruck by the haunting beauty of these codices but until now it seems not to have occurred to anyone that they were painted by priests whose lives were constantly illumined by the unearthly glow of the divine *piule*. From childhood the priests were brought up in its ambiance. Whether the codices were painted while

---

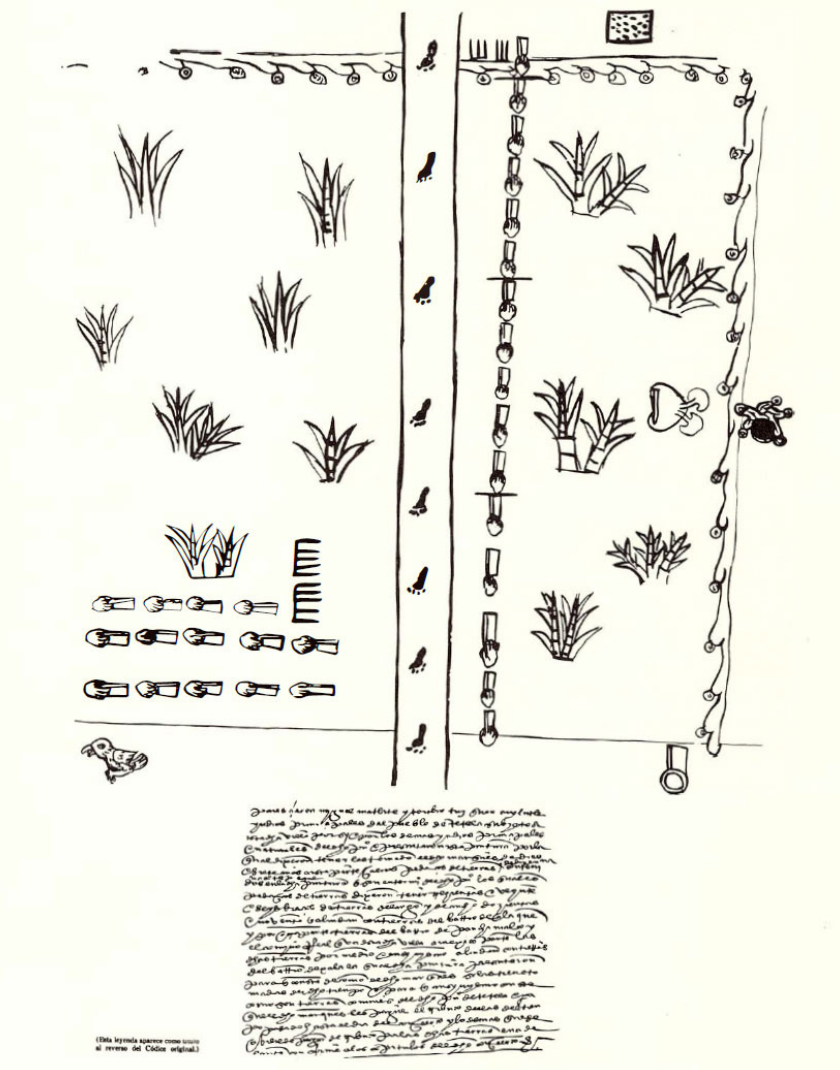
24. For an introduction to this subject the reader is referred to the *Times Literary Supplement*, 5 Jan 1975, 'Communities and their witches', by Robin Briggs, pp 13-14; and 23 July 1976, 'Powers of darkness' by Norman Cohn, pp 902-903.

the priestly scribes were bemushroomed we will never know but I think this may have been possible for the trained *élite*. The *amoxtli* enjoyed a prestige that we sense to this day in María Sabina's chants: the gods themselves dictated these picture writings. This is an æsthetic judgement and is not open to demonstrable proof. On the other hand only those who have known the hallucinogens well and under the right circumstances are qualified to assay my view... How startled and fascinated would Dr Caso have been at our new perspective on his codices!

Códice indígena no 27

Dr Caso began his paper on the *Codex Vindobonensis* with a discussion of another Codex, post-Conquest, dating from 1549, a legal document written in picture writing on one side and in Spanish on the other. He found here solid grounding for his interpretation of the Vienna Codex. (Fig 3) This second Codex was an extraordinary discovery.

The Indians of Tetla in Morelos were filing a complaint alleging that Cortés in 1532 had taken some lands of theirs to make a road running to Mexico City. (Fig 3) The road is plainly indicated bisecting the land with human footprints marking the trail. On the left is a field apparently sown to sugar cane, on the right a terrain bearing the name 'Nanacatepeque'. The glyph for this name appears *inside* the land in question. In picture writing 'Nanacatepec' consists of three words: *nanácatl* meaning 'mushroom', *tépetl* meaning 'hill', and *c*, a locative meaning 'place' - 'Mushroom Hill', . The farmlands that adjoin Mushroom Hill are identified by other glyphs, all of which Dr Caso explains, his explanation being supported by the Spanish summary. In the glyph for Mushroom Hill the mushrooms are shown by a pair of mushrooms represented in cross section emerging from the hill. Dr Caso sees in the pair of mushrooms the identical glyph that we find in the Vienna Codex.



(Esta leyenda aparece como texto al reverso del Códice original.)

Fig 3 *Códice Indígena* No 27

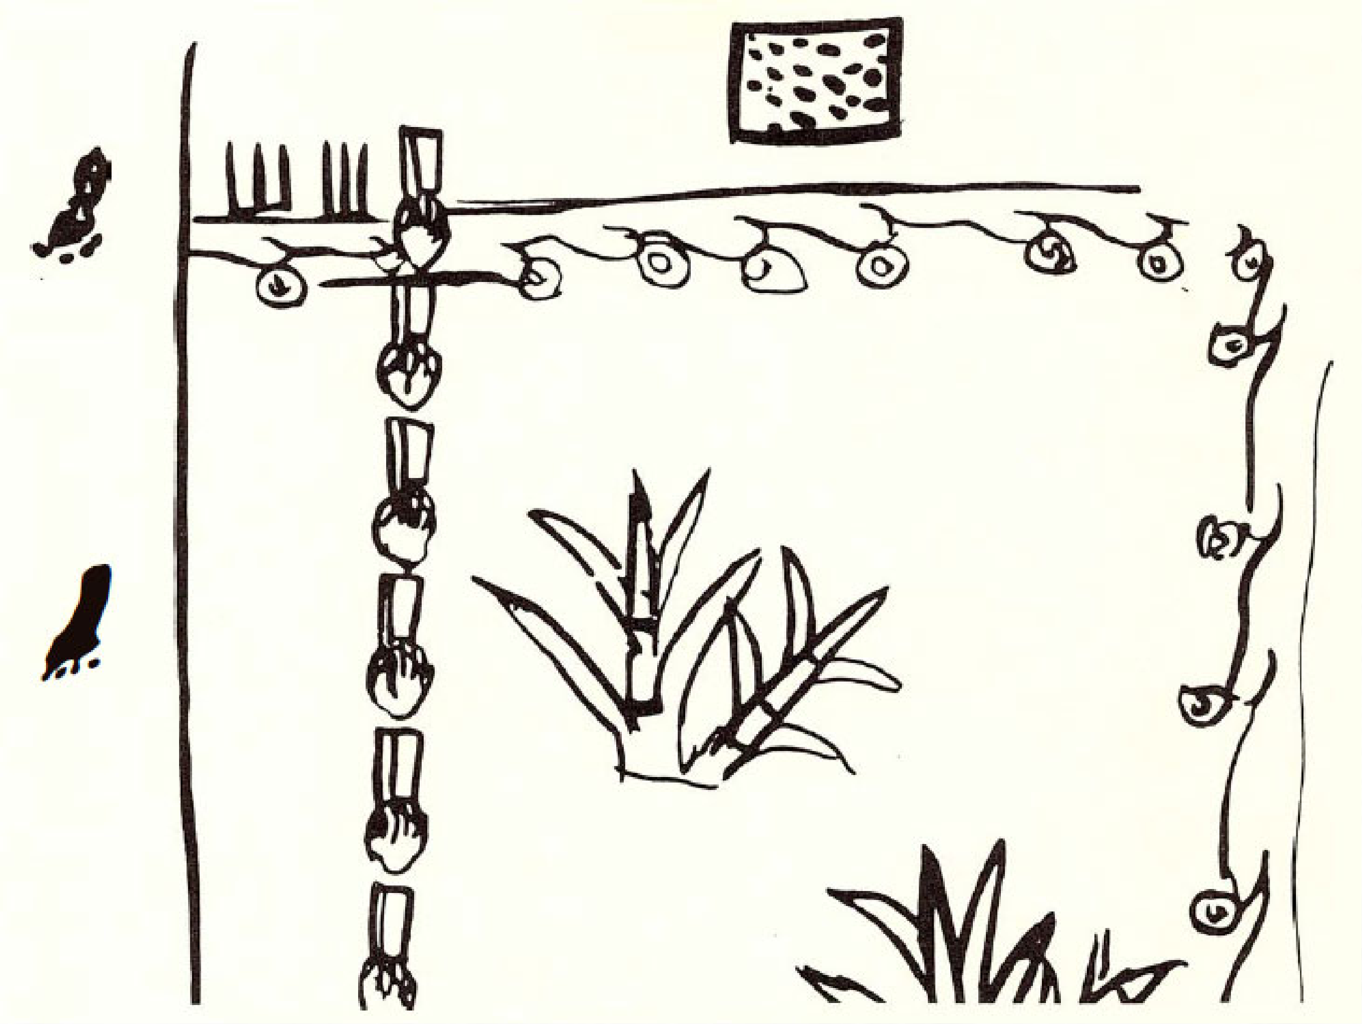


Fig 4 *Códice Indígena* No 27

Before we leave this *Códice indígena* No 27, I will call attention to the two glyphs that mean running water, one along the top of the field and the other down its right side. The wavelets along the top are linked to snails alternating with circles, the circles in turn containing tiny concentric circles, reduced occasionally to a mere dot. Down the right side we find similarly flowing water but expressed here by the circle-and-dot. In the pictographic 'shorthand' the snails are dropped and the inner circle is hardly more than a dot. There is no commoner glyph in the picture writing of Mesoamerica than the one of water represented precisely as here. In this same Codex No 27 it occurs again to the right of Mushroom Hill, in the rebus glyph,  which means 'Olaque', the name of the adjoining village. This glyph consists of *Ol-*, taken from *ollin* meaning rubber, *a* for *atl* meaning water, and the locative *que*. The place name 'Olaque' is thus expressed by a ball of rubber and the symbol for water.

I will revert to these glyphs for water when we come to discuss the Teotihuacán murals.

Sahagún's Florentine Codex and the Magliabechiano Codex

From the beginning of our inquiries into the mushrooms of the Nahua we were on the lookout for sixteenth century illustrations of them. The botanist Hernández in his text said that he was depicting four kinds of mushrooms including the *teyhuinti*, the inebriating one, but the 1790 edition carried no illustrations, and his drawings, which would have been precious for us, must have been consumed in the Escorial fire. However, our quest has not been bootless. In the *Florentine Codex* of Bernardino de Sahagún's famous chronicle and account of the Mexican world we discovered one picture theretofore unremarked by students, and Robert J. Weitlaner has drawn our attention to a second in the *Magliabechiano Codex*. We here reproduce both of them, this having been facilitated by a happy chance: the two codices, though lying in different libraries, are both in Florence. The illustrations are singularly significant for us, being complementary, one of them executed by a Spanish artist and the other by a native in the tradition of his people, though he may show traces of Spanish influence. Both illustrations are in the nature of pictographs, vignettes intended to convey a verbal message. Neither tells the mycologist anything about the sacred mushrooms, but both are eloquent and curious expressions of the contrasting attitudes of the two peoples toward them.

Sahagún's writings survive in several depositories, the *Florentine Codex* in the Biblioteca Laurenziana being the best known. Although most of the many illustrations in it were done by native artists, some were by Spaniards, and it was a Spaniard who made the five small pictures representing various mushrooms that Sahagún discussed. A close inspection of the five pictures and Sahagún's text makes it clear that the artist worked from the text and possessed no knowledge outside the text. (Did Fray Bernardino think it safer not to turn to a native of Mesoamerica to depict the dangerous mushroom?) When he came to the inebriating mushroom, the painter undertook to convey his iconographic message in a way natural to a sixteenth century Spaniard: a demon is portrayed rising from a number of nondescript tawny mushrooms and the demon carries those conventional stigmata commonly identified with demons in the Gothic and Spanish worlds. He is clothed cap-à-pie in fur, a huge beak emerging from his fur-enclosed face. For hands he has claws. One foot is unformed or malformed, perhaps a splayfoot. This is the malformed foot that survives in the English 'cloven hoof', that led the French to speak of the Devil as *le Bot*, the Clubfooted One, the Cripple.[25] In *le Bot* as in this picture we find blended the themes recurring in our writings - Satan portrayed as *le Bot*, a demonic mushroom, also called *le Bot* in Old French, and offstage, by metaphoric transfer, the toad again in Old French called *le bot*. The common toad was a focus of execration in Western Europe at that time, an attitude that runs back far and deep in West European history. In the 'witchcraft' trials of the Middle Ages I have nowhere found reference to mushrooms, but as a common denominator lying behind ordinary words of everyday use, we find Devil, toad, and toadstool. Did the Catholic clergy in Mesoamerica sense this ancient layer of meaning linking these three - Devil, toad, and toadstool - in an unholy trinity?

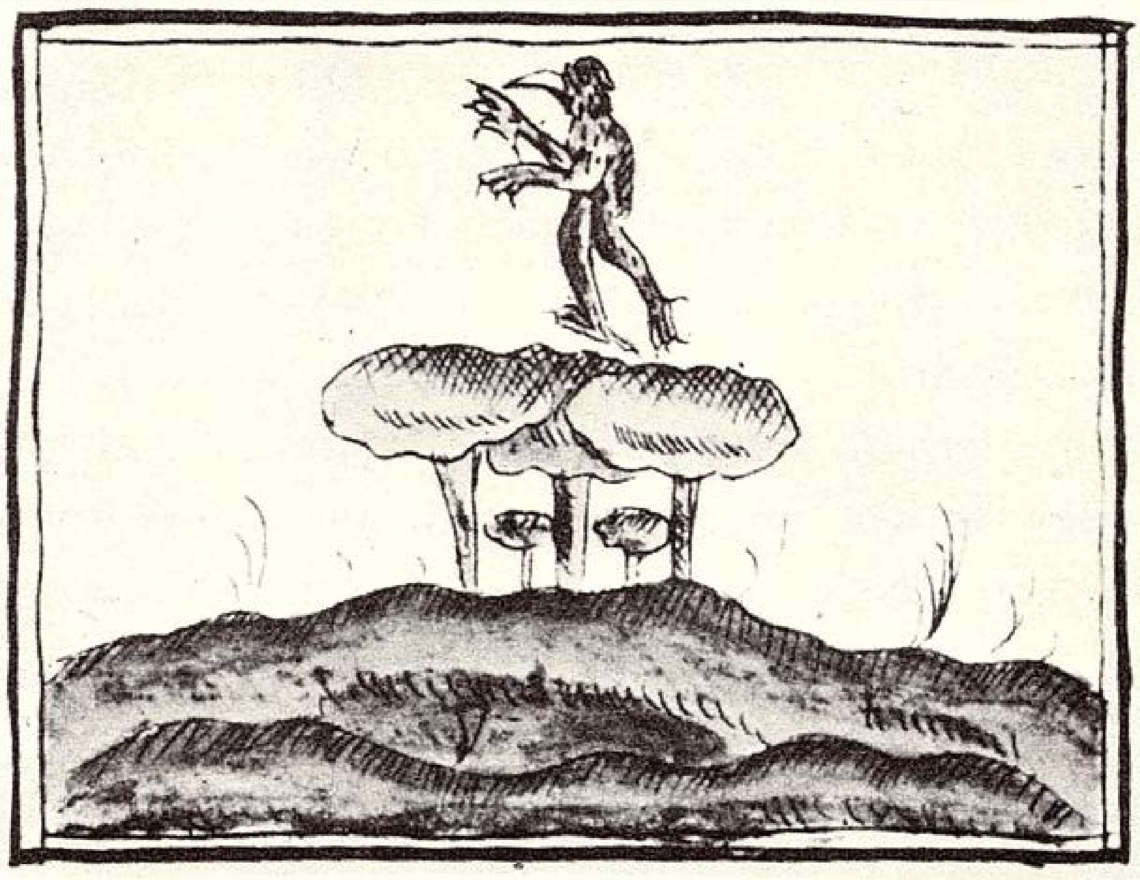

Fig 5 Illustration of Satanic Mushroom. *Florentine Codex*

---

[25] Malformed and bestial feet characterize several Aztec divinities. Thus the god Tezcatlipoca was distinguished by a missing or

> deformed foot. But it would be rash to assume that the demon of the *Florentine Codex* was influenced by Nahuatl artistic conventions. The craftsmanship reveals a European mind, the dubious visual expression corresponding to the verbal denunciations that the clergy were heaping on the 'demonic' mushrooms.

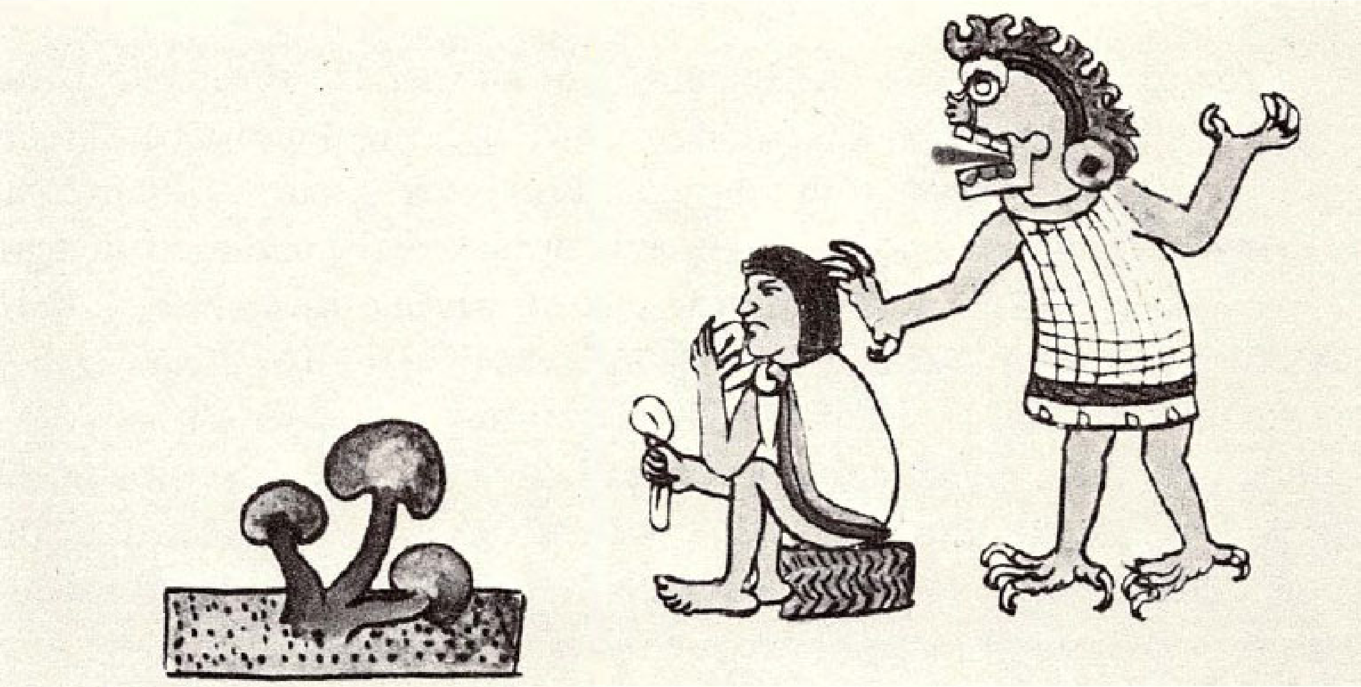

Fig 6 Illustration from *Magliabechiano Codex*

The second illustration, in the *Magliabechiano Codex*, offers us three elements - mushrooms, a man eating the mushrooms, and behind and over him a supernatural figure. The reader will note that the man holds a mushroom in each hand, *ie* a pair. According to Professor Jiménez Moreno, the spirit is probably Mictlantecuhtli, Lord of the Underworld, who is depicted on other pages of the same Codex. The Codex is painted on European paper, and dates probably from shortly after 1528. How far removed from the Spaniard's conception is the native's! Not only is the craftsmanship of these artists, contemporaries of each other, poles apart: their message is likewise. The Spaniard is reporting prosaically the existence of a demonic mushroom to his European public. The Indian, though undoubtedly a baptized Christian, conveys a sense of the reverence that he still feels in the presence of the awesome *teonanácatl*. That the mushrooms in this miniature are green should not disconcert the mycologist: green, the color of the precious jade, meant in Mexican iconography that the object so depicted was of great worth, was holy.

Matrícula de Huexotzinco

In 1560 a census was taken of Huexotzinco, not only of the town but of the whole province. In pre-Conquest times Huexotzinco was a famous city not many miles from the lake, also famous, in which Mexico-Tenochtitlan was built. The census of everyone in Huexotzinco was written in duplicate, the names spelled out in Roman characters and also drawn in the picture writing of the Nahua. Karl-Herbert Mayer has drawn my attention to two individuals in the list of names called *Xochinanácatl*, a word that, as we already know, means 'sacred mushroom'. We do not know why these individuals were so called. Were they specialists in the gathering and use of the mushrooms? Or were these names unrelated to the mushrooms? Here are the pictographs for Luis and Diego Xochinanácatl, two of the entries in the Census of Huexotzinco for 1560:

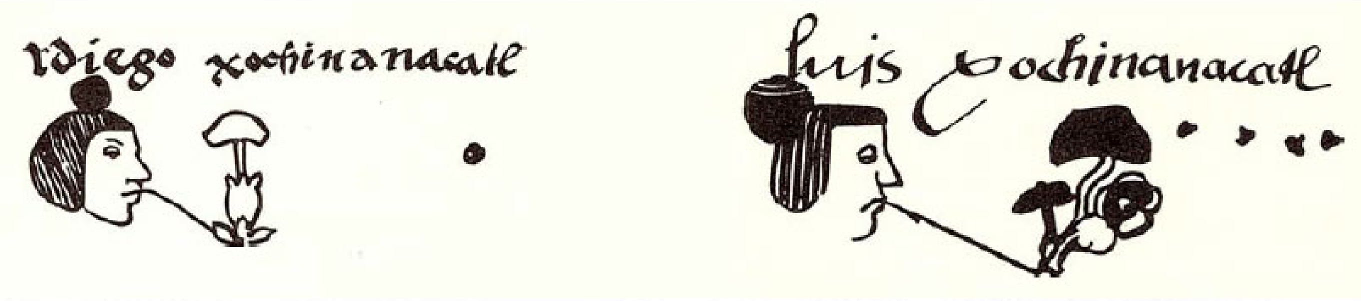

Fig 7 Men named for the Sacred Mushroom. *Matricula de Huexotzinco*

In each case, as well as all other cases in this census record, a line invariably connects the face to the drawing that represents him. It will be noted that one spot on the right distinguishes the pictograph of Diego who is represented by one mushroom, and four spots accompany the pictograph of Luis who seems to be blessed with four mushrooms. What this means we know not, but it certainly meant something to the artist.

Fig 8 *Lienzo de Tlacoatzintepec*

In April 1952 Robert J. Weitlaner discovered a *mapa* in the Chinantec village of San Juan Tlacoatzintepec, a map drawn in the picture-writing of the Indians dating back perhaps to the late sixteenth century or the early part of the seventeenth. The original, badly dilapidated from age, was drawn on tightly woven cotton cloth.

Fortunately it was copied in March 1892, and a tracing of this copy was made by Carlo Antonio Castro, Weitlaner's colleague. This typical post-Conquest Codex is reproduced in Fig 8. It represents a momentous event in the history of the village, a battle over lands between the village of Tlacoatzintepec and a neighboring town. We will dispense with the reading of the *mapa*, of interest to specialists, and concentrate on the crossed mushrooms in the upper right-hand corner, of which we supply the detail in Fig 9. Weitlaner was in no doubt that they represented the sacred mushrooms: ordinary mushrooms would never enjoy the prestige to be included in a *mapa* esteemed and guarded by the villagers as this one was. The same would hold true of the *Códice* No 27 previously described. No mountain or hill would be named after ordinary mushrooms edible or inedible. In examining the *Lienzo*, the reader will smile on noting that the divine mushrooms are next to a Christian cross.

In the Bibliothèque Nationale, Paris, there survives a post-Conquest Codex with this title executed shortly after 1540. It is on *amate*, the native beaten bark paper, and shows Indian-style the disposition of the official buildings around a court of the city of Texcoco. The Lord of Texcoco and his son occupy the central chamber of the upper tier of rooms. (Fig 11) Karl-Herbert Mayer of Graz called my attention, in the upper left-hand quarter of this chart, to what he thought might be mushrooms, only to revise his opinion on closer inspection, under magnification, of these four curious objects. (Fig 12) He discovered that the stipes (or stems) of the 'mushrooms' were all separated from the 'caps'. When he first wrote me I was inclined to accept his identification, and when I discovered that the stipes were on their own, so to speak, contrary to his reaction, I was sure that we were dealing with mushrooms.

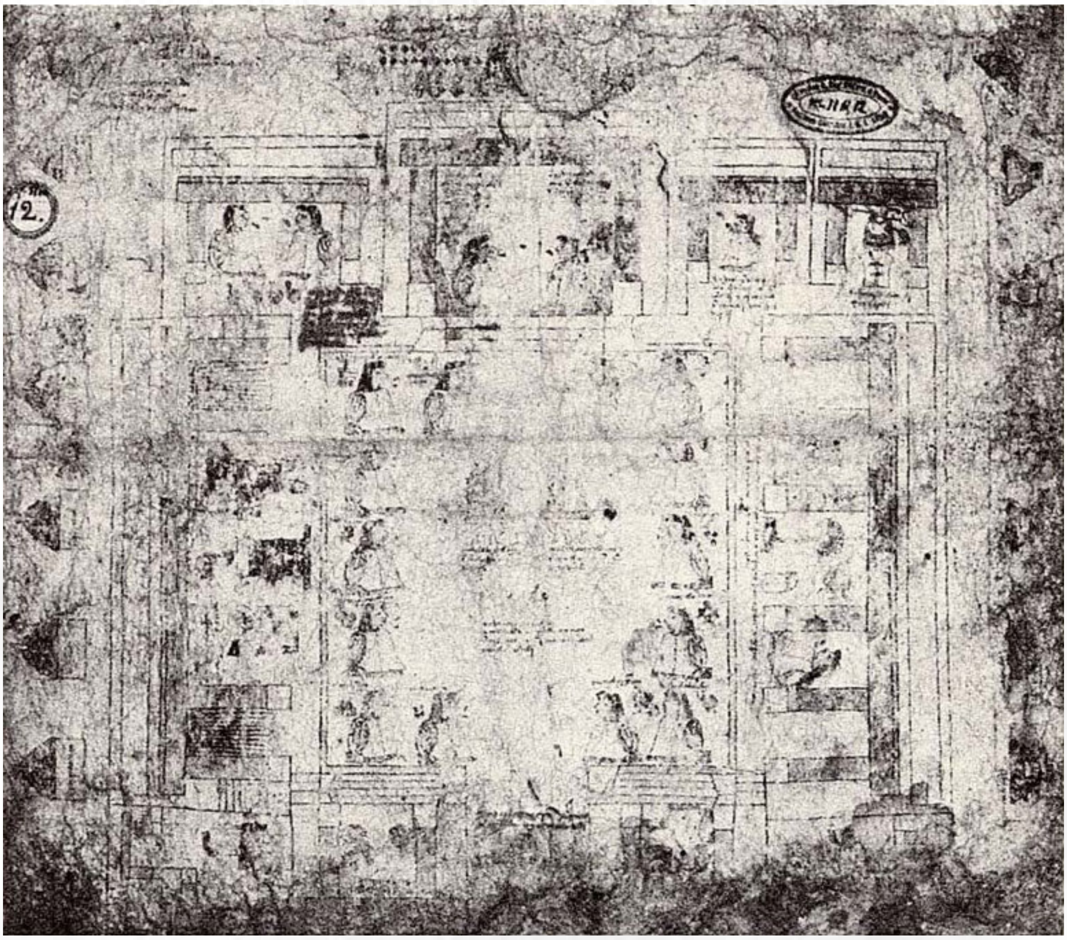

Fig 10 Photograph of original *Mapa Quinatzin*, Bibliothèque Nationale, Paris

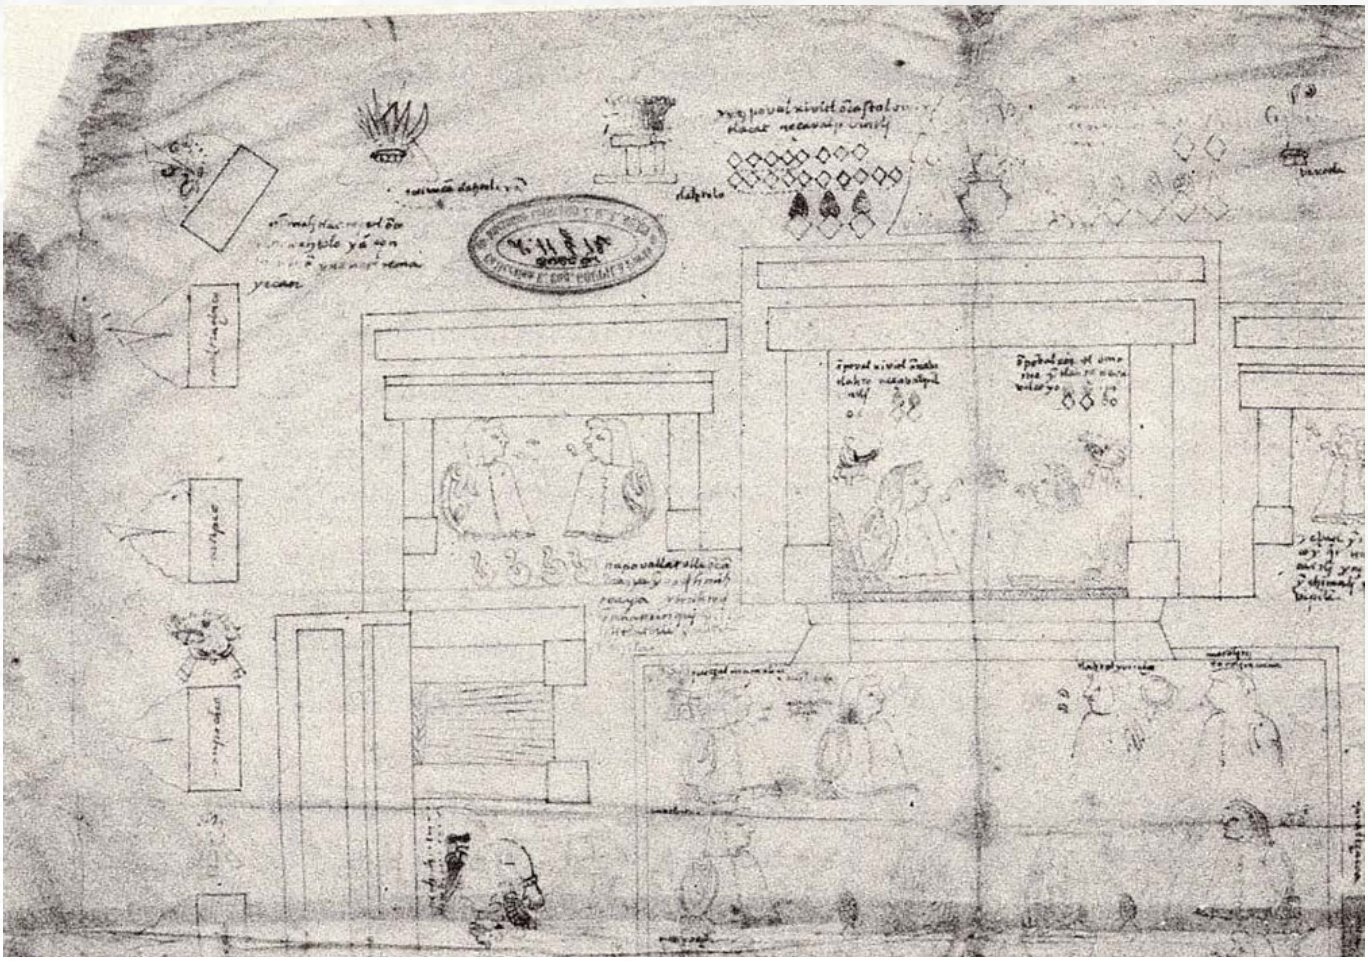

Fig 11 Drawing after *Mapa Quinatzin*, detail of upper left hand corner

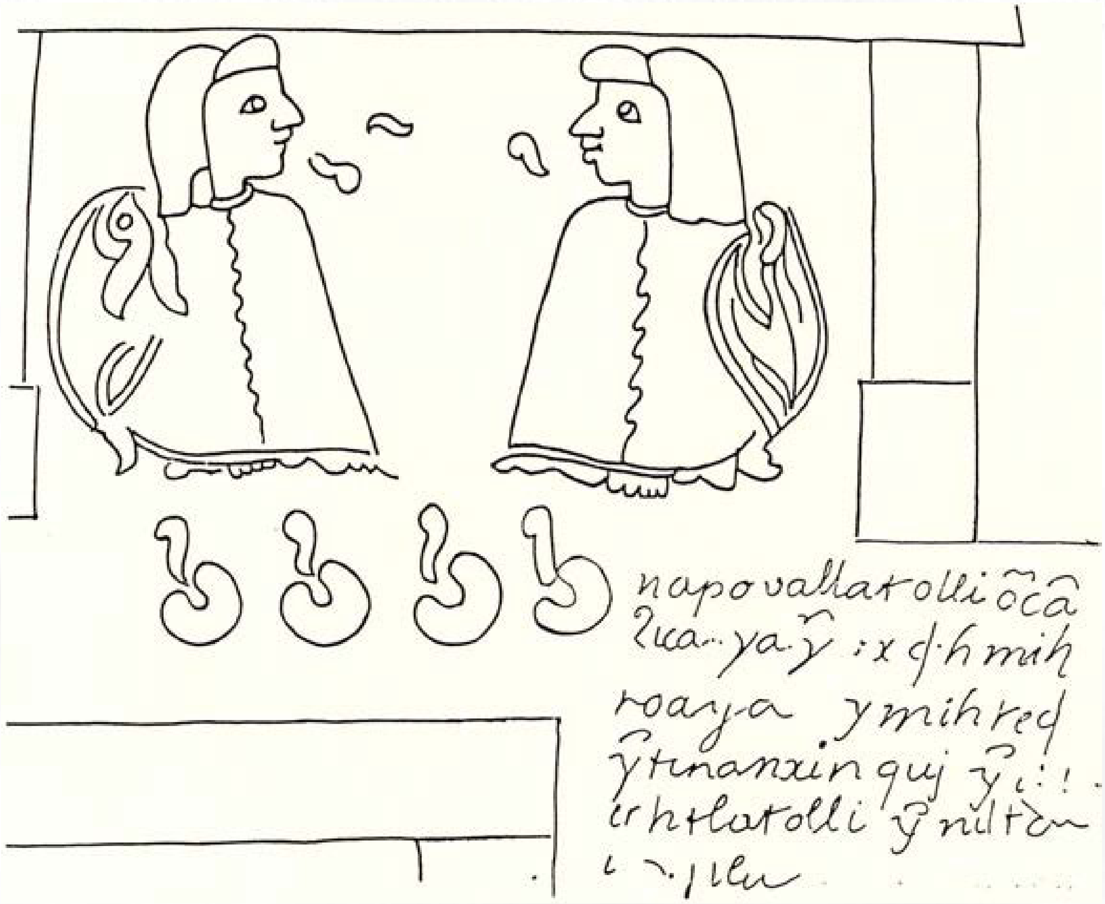

Fig 12 Further detail of drawing after *Mapa Quinatzin*

This chart bears explanatory comments and one of them deals with the two individuals seated in the room above our mushrooms. It explains that this is the audience chamber where justice is rendered: an audience in which the rights in certain lands are being adjudicated. The comments are in Nahuatl written in our alphabet. There is agreement on the translation as far as it goes.

Whether the two figures are colleagues discussing the merits of the case, or whether one is a judge (presun1ably the one on the left) and the other the plaintiff or the defendant, I would not say. They are both speaking, the one on the left uttering two *vírgulas de habla*, 'commas of speech', the other only one. *Vírgulas de habla* is the customary way to designate in Spanish these common glyphs for speech in Mesoamerican writing. And *vírgulas de habla* are what the mushrooms are uttering, the divinatory mushrooms, speaking with the voice of the gods. The court is having recourse to *xochinanácatl* to arrive at the just decision. The mushrooms are playing their proper rôle.

This *Mapa Quinatzin* has been described at length by Mesoamerican scholars, the Nahuatl comments translated, but apparently no exegete has ever remarked on these mushrooms uttering their *vírgulas de habla*. I shall never forget Aurelio Carrera's arresting characterization of the sacred mushroom: *es habla*, it is speech, it is the Word.

CHAPTER 7
Piltzintli, Child God of the Nahua, and his Christian progeny

Santa María Tonantzintla

A reader unfamiliar with the world of the Middle American Indian and acquainted only with the text of our *veladas* might jump to the conclusion that the divine mushrooms are primarily a device for predicting the outcome of a particular illness in a particular individual. True, this was the purpose of the shamanic sessions that we have offered to the public. But the horizons conjured into being by the mushrooms are far wider in time and space, and beyond time and space, than the mere outlook for a stricken patient. They translate one to a prismatic, iridescent, pristine world, a Garden of Eden and a Tlalocan, fields of asphodel, well watered, clean, where the air and the breezes are good, where birds and butterflies and flowers abound, where men live off nectar and ambrosia. The divine mushrooms step up our drab existence to heights of great poetry and music. Those who commune with them find opening before them the portals to the playing fields of the gods.

And here I will interrupt my exposition to recapitulate certain developments in recent Middle American studies.

In 1942 Alfonso Caso brought out a brilliant paper[26] in which he reported on the uncovering of a mural in the sacred precincts of Teotihuacán, a mural that he called Tepantitla after the *solar* or villa where it was found. Enough of the mural (painted probably between A D 300 and 600) survived to show that it portrayed Tlaloc the Rain-god, and Tlalocan his heaven. This heaven was a lovely scene of natural beauty where the chosen among the dead disport themselves in various games and pastimes. The Aztecs placed Tlalocan traditionally in the folds of the mountains below Popocatepetl.

In some quarters doubts have been expressed as to whether Dr Caso was justified in assuming that the ideas and ideology of the Nahua of the fifteenth century could be projected back a thousand years into the Teotihuacán culture. I do not share these doubts. In our days of dizzy and accelerating technological change we must make an effort to picture a stable world of unchanging ways, a world without an alphabet, without even draft animals to help in the performance of manual labor. Though we are not sure what language was native to Teotihuacán, we can be reasonably certain that, whatever the tongue spoken there, the ideas and habits of life were substantially unchanged until the arrival of the Spaniards - figures of Outer Space - erupted on the scene early in the sixteenth century.

In 1951 there was published a collection of papers in honor of Dr Caso and among them was a brief one contributed by Francisco de la Maza in which for the first time the Tlalocan of pre-Columbian days was linked with the Christian church of Santa María Tonantzintla near Cholula, a nineteenth century church that is almost in the shadow of the great Cholula pyramid and is within a long day's walk from the upland valleys where lay the Tlalocan of the pre-Columbian beliefs. There lie, over the crest of the mountains, San Pedro Nexapa and Amecameca where the sacred mushrooms are still consumed and consulted. Cholula is only a short distance away in every direction from the *teonanácatl* and *ololiuhqui* country. Each year in mid-September when the sacred mushrooms abound the Indians still go on pilgrimage to Cholula and thereabouts. Tonantzintla is also near Puebla, about a third of the way from Mexico City to Huautla. De la Maza perceived that the remarkable interior of the church of our 'Little Mother' is decorated, not precisely in baroque or Churrigueresque style, but in a folk style consonant with the astonishing display of Churrigueresque extravagances manifesting themselves at that moment in Puebla. Those extravagances - did they not give an opportunity to the parishioners of Tonantzintla to indulge in aberrations of their own that were wholly of pre-Conquest inspiration? Throughout the interior of the church of Tonantzintla, De la Maza saw the Nahua *xochime* (flowers), *piltontli* (children), *ixtli* (faces), their wide-open eyes speaking for their amazement at finding themselves in Paradise, *xayacatl* (masks) covered with *ihuitl* (feathers) feasting on *xochicualli* (fruits). De la Maza's discovery deserves conspicuous honor, associating as he dared to do the pre-Columbian culture of the Indians with an eighteenth to nineteenth century expression of that same culture in a Christian temple. Here, he thought, was the key to what had been an amazing riddle. In retrospect his reading of the *décor* of this church seems obvious, as all major discoveries seem, once they have been made.

---

[26] 'El Paraiso Terrenal en Teotihuacán', *Cuadernos Americanos*, Nov-Dec 1942, pp 128-136. His identification of the central figure as Tlaloc has been formidably challenged by George Kubler in *The Iconography of the Art of Teotihuacán* published by Dumbarton Oaks, 1967, and by Peter T. Furst in *Mesoamerican Archeology, New Approaches*, ed by Norman Hammond, Duckworth, 1974, pp 187 ff. This question is irrelevant to my argument.

Then, in 1956, there came a little book by Pedro Rojas, *Tonantzintla*, illustrated with seventy-six of his photographs. It was a spectacular essay on the parish church of Santa María. The idea only adumbrated by De la Maza here unfolds, fills out, and takes flight. In words of extraordinary eloquence, interlaced with Father Garibay's translations of Nahuatl poetry, he discourses in minute detail and with authority on the decorations of this famous fane, a supreme expression of the religious belief and aspirations conceived and executed by the humble parishioners of this neighborhood.

Caso, De la Maza, Rojas - these men went far in interpreting Tepantitla and Tonantzintla. They omitted only one element, an element that supplies the keystone to the arch - the sacred mushrooms, *teonanácatl* and *xochinanácatl* of the Nahua, ˀnti^{1}xi^{3}tho^{3} of the Mazatecs.

I had visited Tonantzintla before attending a *velada* conducted by María Sabina. Here was a simple village church where the folk art of the parishioners ran riot over ceilings, walls, and sanctuary, *hauts-reliefs* of flowers and fruit, of children and faces mostly young, some singing, some with masks, others making music on stringed instruments, many joyfully naked, the whole area of walls and vaults, columns and pilasters, crowded with these figures in a riotous display of vivid colors and bewildering curves. I had already stood, like thousands before me, struck dumb at the spectacle, wondering what *genius loci* had inspired the farmers and artisans of this neighborhood to let themselves go, decorating their church in so unorthodox, so dazzling, a fashion, with no parallel in Mexico, in the whole world. What a spontaneous outpouring of joy in life!

On returning to Tonantzintla in 1955 after attending two *veladas* and sharing in the mushrooms (but not understanding what María Sabina was singing), it came over me as a revelation, when entering the church, that these were the color values, the phantasmagoria, of the mushroom world. There was not the slightest doubt in my mind. But how could I prove this to people who had never taken the mushrooms, would never do so?

★

In 1957 Valentina Pavlovna and I brought out our *Mushrooms Russia & History*. In it we presented our reasons for believing that the Tepantitla and Teopancaxco murals, both from roughly the same period perhaps fifteen or sixteen centuries ago, are shot through with unmistakable mushrooms. The mushrooms alternate with marine snails and bivalves, in a manner that we all recognize at a much later date as a glyph for water. In these murals the mushrooms, not yet stylized beyond recognition, are mushrooms, not the 'jade rings' that some have surmised, nor the water lilies that others have suggested, for they lack the deep cleft in the leaves that characterize the water lily. In *Les Champignons hallucinogènes du Mexique* that Roger Heim and I with others published at the end of the following year, I told the story again, now adding to my illustrations a mural from the *solar* of Zacuala, in Teotihuacán, which was called to my attention by Mme Laurette Séjourné. In this mural we find the same symbol representing, as I believe, *teonanácatl*, a Nahuatl name for the sacred mushrooms, or *xochinanácatl*, that other name supplied in the great sixteenth century lexicon of Nahuatl by Alonso de Molina. But here in Zacuala the symbol stands alone, not with seashells as a glyph for water. Though our book drew wide attention from laity and specialists both, the particular pages in which we pointed out the *teonanácatl* in the murals of the sacred precincts of Teotihuacán seem to have drawn comment from no one: no one except Dr Alfonso Caso who, in the opening paragraph of his paper on the mushrooms in the *Codex Vindobonensis*, referred to us (Heim & the Wassons) as having drawn his attention to the fungal representations in the murals of Teotihuacán.

★

I then went to the Far East and concentrated almost exclusively on the rôle of mushrooms in the cultures of India, China, Japan, New Guinea, and elsewhere. Toward the end of the '60's and early '70's I returned to the Mexican field, re-read Francisco de la Maza's paper and Pedro Rojas's book dealing with the church of Tonantzintla, admired the care with which Fernando Benítez followed in our footsteps and, giving us full credit for our discoveries, reported his talks (through Herlinda Martínez Cid, his and our interpreter) with María Sabina. Above all I studied the *veladas* that Henry Munn, Alvaro Estrada, and we have had rendered from the Mazatec tapes. There is no need for further documentation: on the strength of these *veladas*, whatever Christian overlay it may show, the parish church of Tonantzintla is a pæan to the inebriating mushrooms of Middle America, a pæan almost as inebriating as the mushroom itself, a pæan that surpasses by far even Tepantitla in its exuberant eloquence.

When asked by Fernando Benítez how she viewed the sacred mushrooms, María Sabina had said, as rendered into Spanish by Herlinda Martínez:

> Yo veo a los hongos coma niños, coma payasos. Niños con violines, niños con trompetas, niños payasos que cantan y bailan a mi alrededor. Niños tiernos como los retoños, como los botones de las flores: niños que chupan los malos humores, la sangre mala, el rocío de la mañana. El pájaro que chupa la enfermedad, el chupamirto bueno, el chupamirto sabio, la figura que limpia, la figura que sana.
> [*Los Indios de México*, 3, p 243]
>
> I see the mushrooms as children, as clowns. Children with violins, children with trumpets, child-clowns who sing and dance around me. Children tender as sprouts, as flower buds, children that suck out the evil humors, the bad blood, the morning's dew. The bird that sucks out illness, the good hummingbird, the wise hummingbird, the face that cleans, the face that heals.

María Sabina has never visited Santa María Tonantzintla but do not her words fit that church's delirious *décor*? We recall how in the *velada* María Sabina and her daughter María Apolonia kept singing of the many 'children', ^{ʔ}*nti*^{1}*xti*^{3}, of the 'clowns', *sa*^{4}*se*^{1}.

Pedro Rojas says of the interior of Santa María Tonantzintla words that echo María Sabina's conception of her romping children:

> Niñitos y flores y más niñitos aparecen por doquiera... Es un espectáculo hecho de jardines de niños. Y a todo costo, porque acuden tantos actores que donde no se ven ángeles y amores es porque aparecen caras y más caras y hasta máscaras... Ahí está Tonantzintla con tantos niños y flores que con palabras cantan unos la flor de la vida y otras la vida en flor.
> [Pedro Rojas, *Tonantzintla*, UNAM, 1956, pp 33, 40]
>
> Little children and flowers and more little children appear wherever you will.... It is a pageant of gardens of children. And at whatever cost, for so many actors hasten hither that where angels and winged children are not seen it is because faces and more faces and even masks appear.... There stands *Tonantzintla* with so many children and flowers that in words the children sing of the flower of life and the flowers sing of life in flower.

All these children of Santa María Tonantzintla, who are they? Who but the 'children' of María Sabina's chants and the Benítez interview with her? In her talk with Alberto Ongaro, already cited, she also stressed the 'children' that are the spirits of the mushrooms. Signor Ongaro told me that in Huautla a second shaman (whose name he could not recall) emphasized the same theme. Who are these children but the *a-pipil-tzin*, the 'little children of the waters', of Marina Rosas, the shaman of Aztec lineage, living on the slopes of Popocatepetl a day's walk from Tonantzintla?

Let us carry our inquiry into the 'children' of Tonantzintla further. In the Christian tradition angels, seraphs, cherubs, are all male, reflecting the male-oriented culture that is dominant with us. But in Santa María Tonantzintla little girls with budding breasts bared to the world are there along with the naked boys. We may assume that among the children who are clothed there are girls and boys. In Tlanixco, a Nahuatl-speaking community on the other side of Mexico City near Tenango del Valle, the entheogenic mushrooms are called *siwatzitzintli*, a word meaning 'little women' and conveying a feeling of affection and respect. In Spanish they are *mujercitas*, *señoritas*, or *niñas*, and sometimes the Spanish words are used when the village folk speak in Nahuatl, the hispanicisms nowadays coming natural to the villagers even when they use their native tongue. In June 1960 I taped a discourse in Nahuatl on the sacred mushrooms in Amatlán de los Reyes, Veracruz, by the informant Felipe Reyes F., 60 years old, and when the text was translated by Luis Reyes G., we find the 'young people' answering the questions put to them by the shaman. In a footnote to the translation Luis Reyes, a Nahuatl speaker himself, adds this comment in Spanish on the youths who appear:

> These youngsters in other contexts are called *xocoyome* and they dwell in Tlalocan with Tlaloc and his wife. They are children who die unbaptized and for that reason go to Tlalocan and there become blue in color. They hold in their hands snakes that serve as whips to drive the clouds. By another name these children are known as Lightning Bolts.

But these figures of speech are not confined to the Mazatec and Nahuatl worlds. In my early Mesoamerican peregrinations I did not know enough to inquire of my informants and shamans about the 'children': they are probably present wherever entheogens are used. In the Zapotec country, Thomas MacDougall reported in 1960 that after the inebriating seeds of the morning-glory are taken, and where silence and solitude reign, the *badu-win* (two little girls) appear dressed all in white to reply to the questions that are put to them. Arthur Rubel has said that in the Chinantla in 1971, when he attended his mushroom session, 'little people' answered the questions put to them by the shaman. They are *chamacos* ('children') of both sexes but are small, of the height of the mushrooms themselves.

Perhaps a related association with children is found to this day in the Mixtec culture: the sacred mushrooms were formerly gathered just as day was breaking by *doncellas* ('maidens', 'virgins'), and even now the mushrooms are still ground on the *metate* by *doncellas*. We learned all this when we visited the Mixteca in 1960 with Robert Ravicz. In outlying *rancherías* of the Mixteca it seems likely that even now *doncellas* still gather the mushrooms on the dewy mountain slopes as the sun is about to come up.

María Sabina's *velada*, sung in the depth of night in the distant mountains of the Mazatec country, turns out to evoke responsive chords from diverse quarters of the Mesoamerican world and far beyond, even to the far reaches of the Siberian forest belt, where the 'fly-agaric girls' respond to the shaman's summons. They answer questions and play all sorts of tricks.

The artisans of the parish of Santa María Tonantzintla conceived the design of their church in the second half of the eighteenth century and work on it continued until around 1900. Over this long period the unity lay not in a plan laid down by some famous architect but in the continuing conception of their church held by the community. When the work began, all over Mexico the prestige of the style of architecture known as Churrigueresque was at its apogee, and a supreme example of this extravagant variation on the baroque is to be seen in the Capilla del Rosario in the Church of Santo Domingo in Puebla only a few miles away. We may safely assume that the parishioners of Tonantzintla were familiar with what was going on in this famous *capilla*. There also *angelitos*, cherubs and seraphs, are scattered about, their faces peering forth from nooks and crannies, many flying through the air usually with wings. In the Capilla there are differences, however. The figures are less numerous and they look alike, bland, devoid of expression, repetitive. (Perhaps the craftsmen were paid by the piece.) Here indeed we find 'cherubim and seraphim' who 'continually do cry, "Holy, Holy, Holy"' in a boring Christian heaven. In Tonantzintla every child is bursting with joy each in his own way, excited, gesticulating, addressing the onlooker wholly absorbed in the astonishing pleasure of living. There are fewer of the figures with the conventional wings of European style. The Churrigueresque of the Capilla del Rosario certainly put ideas into the heads of the Tonantzintla parishioners, but then they stretched those ideas to the limit.

When we took our photographs of Santa María Tonantzintla we dealt with the lay officials of the church whose names spoke for their Nahua origin: the *Jefe de Iglesia*, Fiscal Amado Moyd, the *Mayordomo* Onésimo Teconquey, the *Segundo-Teniente* Crescencio Topia, the *portero* Cecilio Ixmoyotl. They informed us that the old people thereabouts still spoke *mexicano* (Nahuatl). Down through the nineteenth century Nahuatl must have been the tongue of everyone.

In that eighteenth century generation of luxuriant ecclesiastical architecture the Nahua of Tonantzintla must have felt safe in expressing heretical concepts when decorating their church. But were they even aware of their heresy? As in María Sabina's mind, were not the two streams of religious tradition already thoroughly blended and did they not do honor to the Virgin Mother by expressing their reverence for the *Santo Niño* plunging headlong into the center of her temple?

We have linked her *velada* with the thinking and feeling of the shamans of the Nahua, as preserved for us in Ruiz de Alarcón's treatise, rendered into Spanish by the distinguished Nahuatlato Alfredo López Austin. María Sabina fills out with flesh and blood the interpretation of Santa María Tonantzintla that had been adumbrated by Francisco de la Maza and fully developed by Pedro Rojas. Her world of the entheogens, gay with creatures and flowers, is peopled with the same order of little sprites that are equally active in the vast reaches of Siberia, where the 'little girls' evoked by *Amanita muscaria* play the rôles that we know are also elicited by the species of Psilocybe of Mexico. Her extraordinary world completes with eloquence what we are already perceiving among the Nahua, the Otomí, the Mixtec, the Zapotec, the Chatino, the Mixe, the Matlatzinca, and the Chinantec. She clothes with rich vesture what were little more than the dry bones of their vocabularies for the entheogens.

★

Listen now to this: Pedro Rojas is baffled by a theological enigma. Occupying a key position in the church is a figure that has no Christian interpretation. Our Lady is enshrined, and properly so, in a ciborium that rises above and behind the altar. Directly in front and above Our Lady, at the peak of the dome of the crossing, is the Holy Ghost naturally embodied in a dove. This dove turns his head to the entrance of the church, and is regarding the conspicuous figure of a naked youth plunging head down, back towards us, over the key to the arch of the crossing that leads to the nave. The head is framed with black curly hair. The large size of this figure and its conspicuous location rule out the possibility that we have here a purely decorative motif. A puzzle in Christian iconography, as Pedro Rojas freely declares.

In the parish church of Tonantzintla the 'little children' are scrambling, scampering, all over amidst the fruits and flowers. These *niños* are gesticulating to us, those yonder are trying to explain to us and we almost catch their voices, others are climbing the walls, crossing the arches, swimming in space, flying through the air, all over the inside of the cupola or dome, even up the columns that embrace the ciborium high above and behind the altar. The figure plunging head down that baffles Pedro Rojas is surely the leader of this band, this rout, of children. True, he is not to be reconciled with Christian iconography. But need we confine ourselves in this superb church to Christian iconography? Is he not the 'young, well developed man' of María Sabina's chant, whom she, by an act of religious syncretism has identified with Jesus Christ? Here is the *Príncipe niño* of the Nahuatl world, the Child God of Mesoamerica, the divinity known to the Nahua under various names:

Pilzintecuhtli, or *Teopiltzintli*, or
Piltzinteotl, or *Piltzintli*,

all of them embodying a different aspect of Xochipilli. But today he is also, surely, the Santo Niño de Atocha of María Sabina's *velada*, the Sacred Mushroom, and we discover him as captain of the romping children, the world of the 'dear little people' of the entheogens. In Santa María Tonantzintla even the Evangelists are young. They are bearded, to be sure, but are not grave and venerable oldsters weighed down with their assignments. Their beards are neatly groomed, their garments clean and tidy. They are in their early thirties.

Here then we find the solution to Pedro Rojas' theological enigma: in this Christian Church, dedicated to the Holy Mother of God in our Christian religion, the Holy Child, the Child God, receives equal honor with her. The Holy Child is the Child Piltzintli of the Mesoamerican pantheon, surrounded on all sides by his supporting cast of 400 joyous boys and girls, he himself being the young Sun God, the God of Springtime, of light and warmth and flowers and butterflies and hummingbirds, of music and dancing and song, of the Tree-in-*Flower*, yes of Ecstasy, the god of the miraculous entheogens, the Master of the Divine Revels of Santa María Tonantzintla. The answer to Pedro Rojas' riddle lies in the pre-Conquest pantheon of Mesoamerica.

★

I have reserved until now evidence of a nature to speak only to those who have experienced and are familiar with the divine inebriation of the mushrooms, of *teonanácatl*.

The folk art of Santa María Tonantzintla testifies admirably, in an unexpected way, to the truth of my thesis that it was inspired by the entheogens. Most of the children are blonds, obviously not Indians. Those who ingest the mushrooms do not see what they see in everyday life. They see life immeasurably enhanced, transfigured. They enter into a supernal world that is normally on the subliminal fringes of their consciousness. Of course the Indians would not see Indians. They see (as Henry Munn puts it) important people, high class people, people with power. These people are white, *gente de razón*, *gente güera*. (In Mexican Spanish *güero* has come to mean 'paleface'.) This conception may go back to pre-Conquest times: Quetzalcóatl, the banished god, was to return some day from the East and it is said that Montezuma expected him and his fellows to be white. Here is one of the meanings conveyed to this day in Huautla by that extraordinary multifaceted word of exaltation, ^{2}*nti*^{1}*chi*^{3}*con*^{3}, 'white', the lords and masters of this world, the ultimate in Mazatec terms of enhancement.

Only those who are at home with the mushroom experience are in a position to feel how securely this throng of white children in the Church of our Little Mother of Tonantzintla favors our interpretation.

The Nicho de Hueyapan

In the vicinity of Tonantzintla, within a radius of ten miles, there are churches innumerable, mostly today in ruins. Cholula was a center of religious devotion in pre-Conquest times, and throughout this rich agricultural valley the same devotion prevails today, though the Indians have changed their religion. Yet of all the churches only one other bears a few carvings that are unmistakably of the same inspiration as Santa María Tonantzintla: San Francisco Acatepec, about a mile away on the highway from Mexico and Puebla to Oaxaca.

But Gutierre Tibón has lately drawn my attention to another cluster of carvings of children, markedly different from Santa María Tonantzintla, though in the same lively and highly individual style. They adorn the Nicho de Hueyapan, executed in 1828 by the anonymous Master of Zacualpan. (The date is consonant with Santa María Tonantzintla.) The Nicho was removed from its Church in Hueyapan to the Museo de Cortés in Cuernavaca almost ten years ago. Many of the older inhabitants of Hueyapan still speak Nahuatl and they occasionally go on pilgrimage to Cuernavaca to visit their Nicho. I do not suggest that the Master of Zacualpan was influenced by those who were embodying their conception of Paradise in the children of Tonantzintla. But for his inspiration was he not drawing on the same reserve of winning 'small fry' that we have seen in Tonantzintla and have felt in the words of María Sabina?

As this Nicho de Hueyapan deserves far more attention than it has received, I offer some views of it in Figures 18 to 24. The artist's conception of St John the Evangelist as a lad in his teens (Fig 19) is perhaps unique. In these children, if I am right, is another instance of the happy synthesis of Christian and pre-Christian feelings.

Santo Niño de Atocha

In his *Historia del Nombre y de la Fundación de México*, Gutierre Tibón cites a tradition preserved for us by Fray Antonio Tello (one of the less read early friar chroniclers) that it was the child god Teopiltzintli who guided the Aztecs, somewhere between the third and sixth centuries, on their migration from their ancestral home of Aztatlan ('Aztlan' in today's spelling) to their new site of Santiago Ixcuintla in what is now Nayarit. Here is Tello's text:

> … y el dios que adoraban era una estatua, hecha á manera de un hombre, al cual llamaban Teopiltzintli, que quiere decir nino dios, que es él que guió á sus antepasados cuando los trajo de Aztatlan para que poblasen aquellas tierras; á éste le ofrecían cuentas, conchas y algodón, no le sacrificaban gente, como en otras partes hacían a otros ídolos; sólo le adoraban é incensaban.

> … and the god that they worshipped was a statue, made in the manner of a man, whom they called Teopiltzintli, which means 'child god', who is he who guided their ancestors when he brought them from Aztatlan for them to populate those lands; to him they offered beads, shells

> and cotton; they did not sacrifice people to him, as was done elsewhere to other idols. Only him they worshipped and to him offered incense.

Knowing as we do that the 'Child God' of the Nahua was the spirit of the entheogens, we find him here exercising his proper rôle as the divinatory scout selecting the spot for the new home of his followers. I will now suggest that the Holy Child of Atocha embodies in the Christian era the Child God of pre-Conquest times, the Child God known in Nahuatl under various closely related names. We shall call him Piltzintli.

In the Indian country of Mexico everyone knows the Santo Niño de Atocha but in the villages I have never found anyone, whether Indian or *mestizo*, who could explain what 'Atocha' meant. Often the word is deformed as *eg* 'Antocha'. In the Spanish of Spain *atocha* is a tough esparto grass from which brooms are made, and 'Antocha' as a place name was an area just outside of Madrid where that grass grew in abundance. (Madrid has long since absorbed this *barrio*.) Since the Middle Ages and perhaps beyond there has been in Atocha a basilica dedicated to Nuestra Señora de Atocha, 'Our Lady of Atocha', the Virgin bearing the Holy Child on her knees. In 1523, at the very moment of the Conquest, the Dominican Order received charge of this basilica, and Our Lady of Atocha appears to have been a focus of devotion throughout Spain, perhaps second only to Santiago de Compostela. The present effigy in wood of Our Lady with the Holy Child on her left knee is said to have been carved in the thirteenth century, replacing an earlier one that presumably had become dilapidated, where Our Lady was holding the Child seated on both her knees. There is a tangled fragmentary record of various secondary images in the round (*de bulto*), one of them an effigy for pregnant women who would call for her presence as the labor pains began. This effigy would be borne to the prospective mother's bedside. The figure in the Basilica of Our Lady has always been carved from a single block of black wood and the Holy Child is inseparable from Our Lady. It seems that the cult of Nuestra Señora de Atocha is today in decline. This is as much as I have learned about Our Lady of Atocha in Spain.[27] (Fig 25)

We do not know at what date the Dominicans introduced their cult of Our Lady of Atocha into the New World, nor when Our Lady with the Holy Child ceded her place to the Child alone. The Dominican fathers in Mexico and Spain, though with utmost courtesy, have seemed unable to help us and indifferent to our theme. Somewhere in the archives of the Vatican or of the Dominican Order there must be documentation that will unfold the story. A moment must have come when the Holy Child was wrested from Our Lady's knees (or arms) and elevated to the High Altar in solitary splendor. The deviation clearly responded to a popular need, and the need, I feel sure, was for the Christian Church to supply a Piltzintli incarnate, or rather a Christian surrogate for Piltzintli.

The Dominicans must have formally approved of this substitution, either locally or by an Act of the Order. Did they substitute the Child for the Virgin-and-Child all unknowing? And did they discover the appalling link to the execrated entheogens too late? Was not this discovery behind the queer Spanish costume and accoutrements that the Niño possesses in the stereotyped icon that we all know? The Holy Child is here represented (Fig 26) as wearing a plumed hat, of a style in vogue in Europe in the late seventeenth century, a long gown and cape, sandals on his feet, carrying a shepherd's staff with a basket for flowers in his right hand, and for good measure a sheaf of wheat (rather than an ear of maize) along with a bottle gourd and a *venera*. (A *venera* is the scallop shell that pilgrims to Santiago de Compostela always carried, to eat and drink from and for alms, and as a symbol of their mission.) To this icon there were often added, in the upper corners, tiny insets that illustrate the Holy Child performing the miracles habitual with him, consoling or curing the ill, thwarting crimes of violence, and such like. ('*Santoniño*' is the name of the burglar's 'jimmy' in Mexican Spanish, opening as they both do all doors!) The icons in quantity were crudely painted on tin and in recent decades, as racial amalgamation has progressed and religious indifference has spread, they have made their way in countless numbers into the flea markets of Mexico, grimy from the smoke of centuries of tapers burning in the humblest homes. The costume of the Child in the typical icon did not antedate the last quarter of the seventeenth century and this may indicate when the worship of the Child, rather than Mother and Child, became definitive.

---

[27] For our information about Nuestra Señora de Atocha we are indebted to José Muñoz Rojas of Madrid, and through him to Fray Angel R. Serrano, O.P., and to a religious publication, *La Virgen de Atocha*, issues of December 1971 and February 1972, published in Madrid.

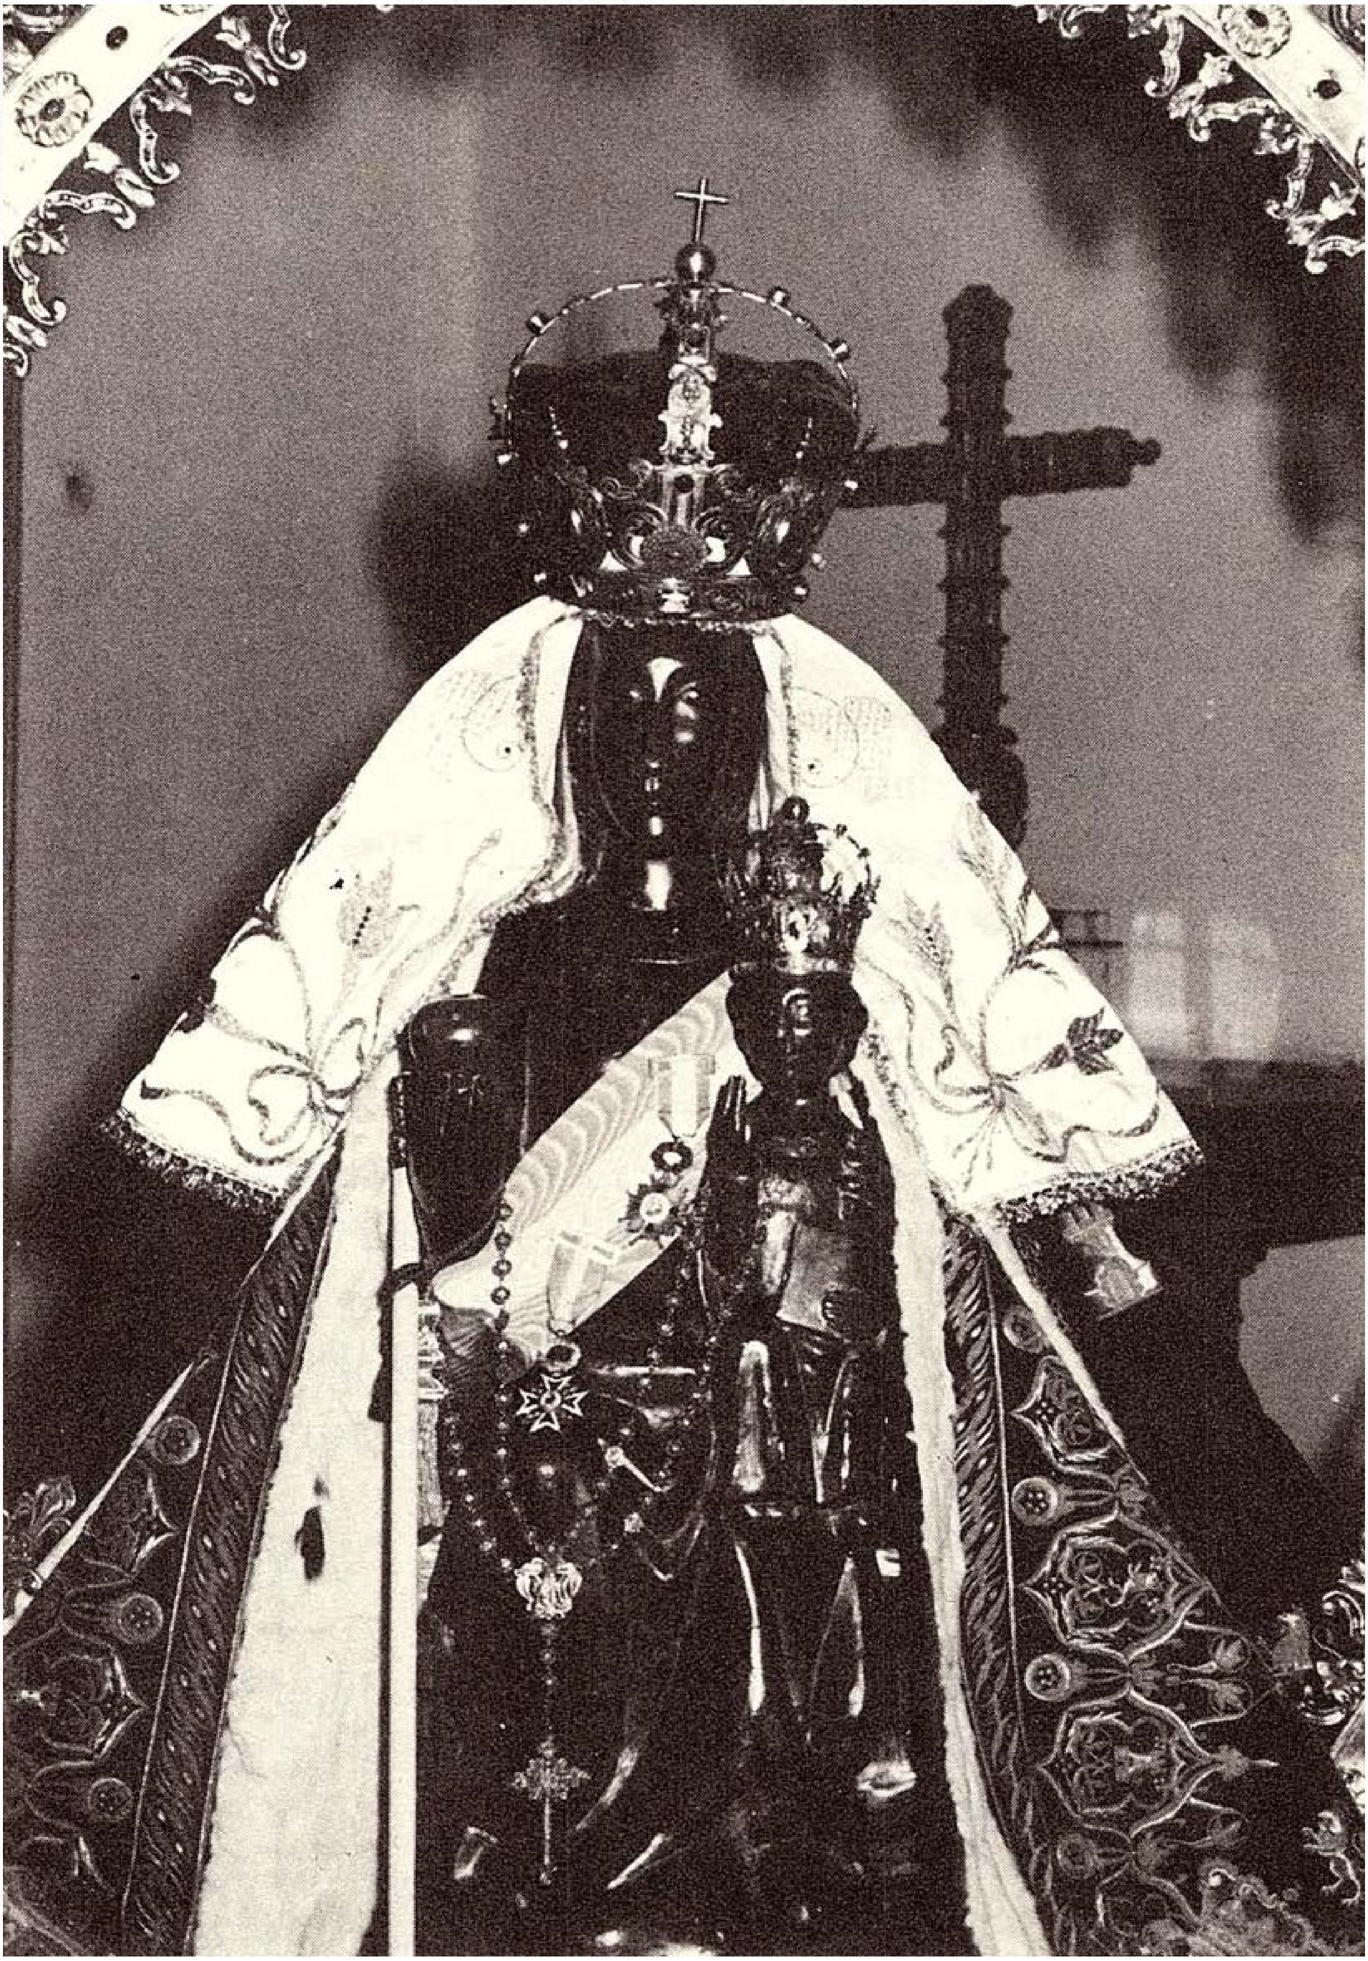

Fig 25 Nuestra Señora de Atocha, in Madrid

Aguirre Beltrán in *Medicina y Magia* gives us a lively account drawn from the Archives of the Inquisition of the various thrusts made by the Indians to find in the new religion of the Conquerors a way to still adore their Piltzintli, although it must be said that the author never suspects the presence of the Child God of the Indians as the motivating force behind their manœuvres. In the early years of the seventeenth century the Holy Office forbade the use of *peyote* (a word that certainly included all the entheogens), and from then until 1630, and again at intervals later for a century, the Inquisition administered by the Dominicans prosecuted those who resorted to *peyote*. As early as 1617 the Indians identified *peyote* with the Niño Jesús, the Child Jesus, in the guise of a lad. Then it is reported that *peyote* became the Holy Trinity, appropriately enough because the Indians, especially the Huichol, linked the cactus with the deer and maize in a mystical triune being. From 1625 to 1665 *peyotl* became identified with Nuestra Señora [de Atocha?], Our Lady. In 1692 we find the entheogen emerging as Santa Rosa María: in those days *rosa* meant 'flower' in Spanish, and 'flower' was *xochitl* in Nahuatl, which as we have seen was a figure of speech for the superior entheogens. In 1713 it figured in the Proceedings as Santa María del Peyote. In 1742 *peyotl* is being called Señor don Pedro, Our Lord St. Peter: who but St Peter holds the keys to Paradise? There have been reports in recent times of a mission in Durángo bearing the name of El Santo Nombre de Jesús Peyotes: this arid region is rich in the famous cactus *Lophophora williamsii*.

In Mexico the cult of the *Santo Niño* has its center, ostensibly, in Plateros, a mining village near Fresnillo in Zacatecas, a dry region where the cactus *peyotl* abounds. The *Santo Niño* is the patron of miners, but the mines around Plateros have declined in importance. The annual festival takes place on Christmas Eve, *la Noche Buena*, and from 20 December on the faithful gather. Here there are no mushrooms nor *ololiuhqui*. In Plateros the immense popularity of the Child Jesus is not among the *indígenas*: his appeal today is exclusively to the *mestizos* and the lower class of Spanish blood, where we do not find the entheogenic plants put to use.[28] Father Miguel Martínez, the incumbent, deprecated to us the 'miracles' attributed to the Child Jesus: *Son creencias populares*, 'They are popular beliefs.' He would have none of them. The Virgin - *Nuestra Señora del Refugio* - is now high up, standing with her arms outstretched, to the left of the altar as the worshipper looks on her. But we see another Virgin on the same plane as the altar and to the worshipper's right as one faces the altar, standing in a white gown with a long blue cape, her arms placed as though holding a baby towards which she directs her gaze with love and adoration. But the babe is gone. We find him above and behind the altar: he is the infant Jesus and his garments are changed daily, according to Father Martínez, being garbed in clothes donated by the faithful. He does not bear the slightest resemblance to the cheap icon representing the traditional *Santo Niño de Atocha*. Being only an infant, he is incapable of performing the miracles expected of the Spanish child-pilgrim of the familiar icon and still more incapable of the feats of the pagan sprites of the entheogens. He is in short finally and completely dissociated from Piltzintli. Are we not justified in supposing that the Dominican friars were aware from an early date of the ambiguity of their Santo Niño, and that in two stages, first as an exotic Spanish pilgrim, lately as an infant, they were interposing distance between their Santo Niño and the Child God of the Mesoamerican world?

There is one other church in Mexico where the Santo Niño is the primary object of adoration: the church of Nundichi, a village high in the hills above Tlaxiaco northeast of this town in the State of Oaxaca, south of the Pan American Highway and halfway to the Pacific Coast. We are here in the Mixteca. The annual feast of this *Niño* is on the first Sunday in January. The *Niño* carries a cross, not a staff, and his head wears a regal *resplandor* (a variety of halo) instead of the plumed hat. (Fig 27) Innumerable pieces of paper with writing on them are pinned to his garment - expressions of gratitude for miracles that he has effected and that are set down for all to read. (These pieces of paper are themselves known familiarly as *milagros*, 'miracles'.) Here also the appeal today is chiefly to *mestizos*. In both centers the *Santo Niño*, according to the popular belief dating from the time when the Infant was a lad, sallies forth from his throne at night to succor the faithful who are in trouble, returning to the church before daylight. The proof (so people say) that these stories are true is the mud (in Plateros) or sand (in Nundichi) that sometimes clings to the sandals when he resumes his place on the altar. But Father Martínez in Plateros dismisses these stories with a wave of the hand. The *sacristán* of the church in Nundichi pointed to another church in a village some miles away across the valley, San Antonio Indoajico, where there is, he said, the cult of a Virgin of Atocha.

---

[28] On our visit to Plateros in January 1972 we were told by Father Martínez that this church draws no *indígenas*. *Sólo la gente adora al Niño*, 'Only people worship the Child', Indians not being people in his mentality. His offhand use of this contemptuous expression is a legacy of Colonial Mexico and is seldom heard now.... Two centuries ago, of course, the mining population of Plateros and the Fresnillo area may have included large numbers of monoglot Indians who adored a 'Santo Niño del Peyotl'.

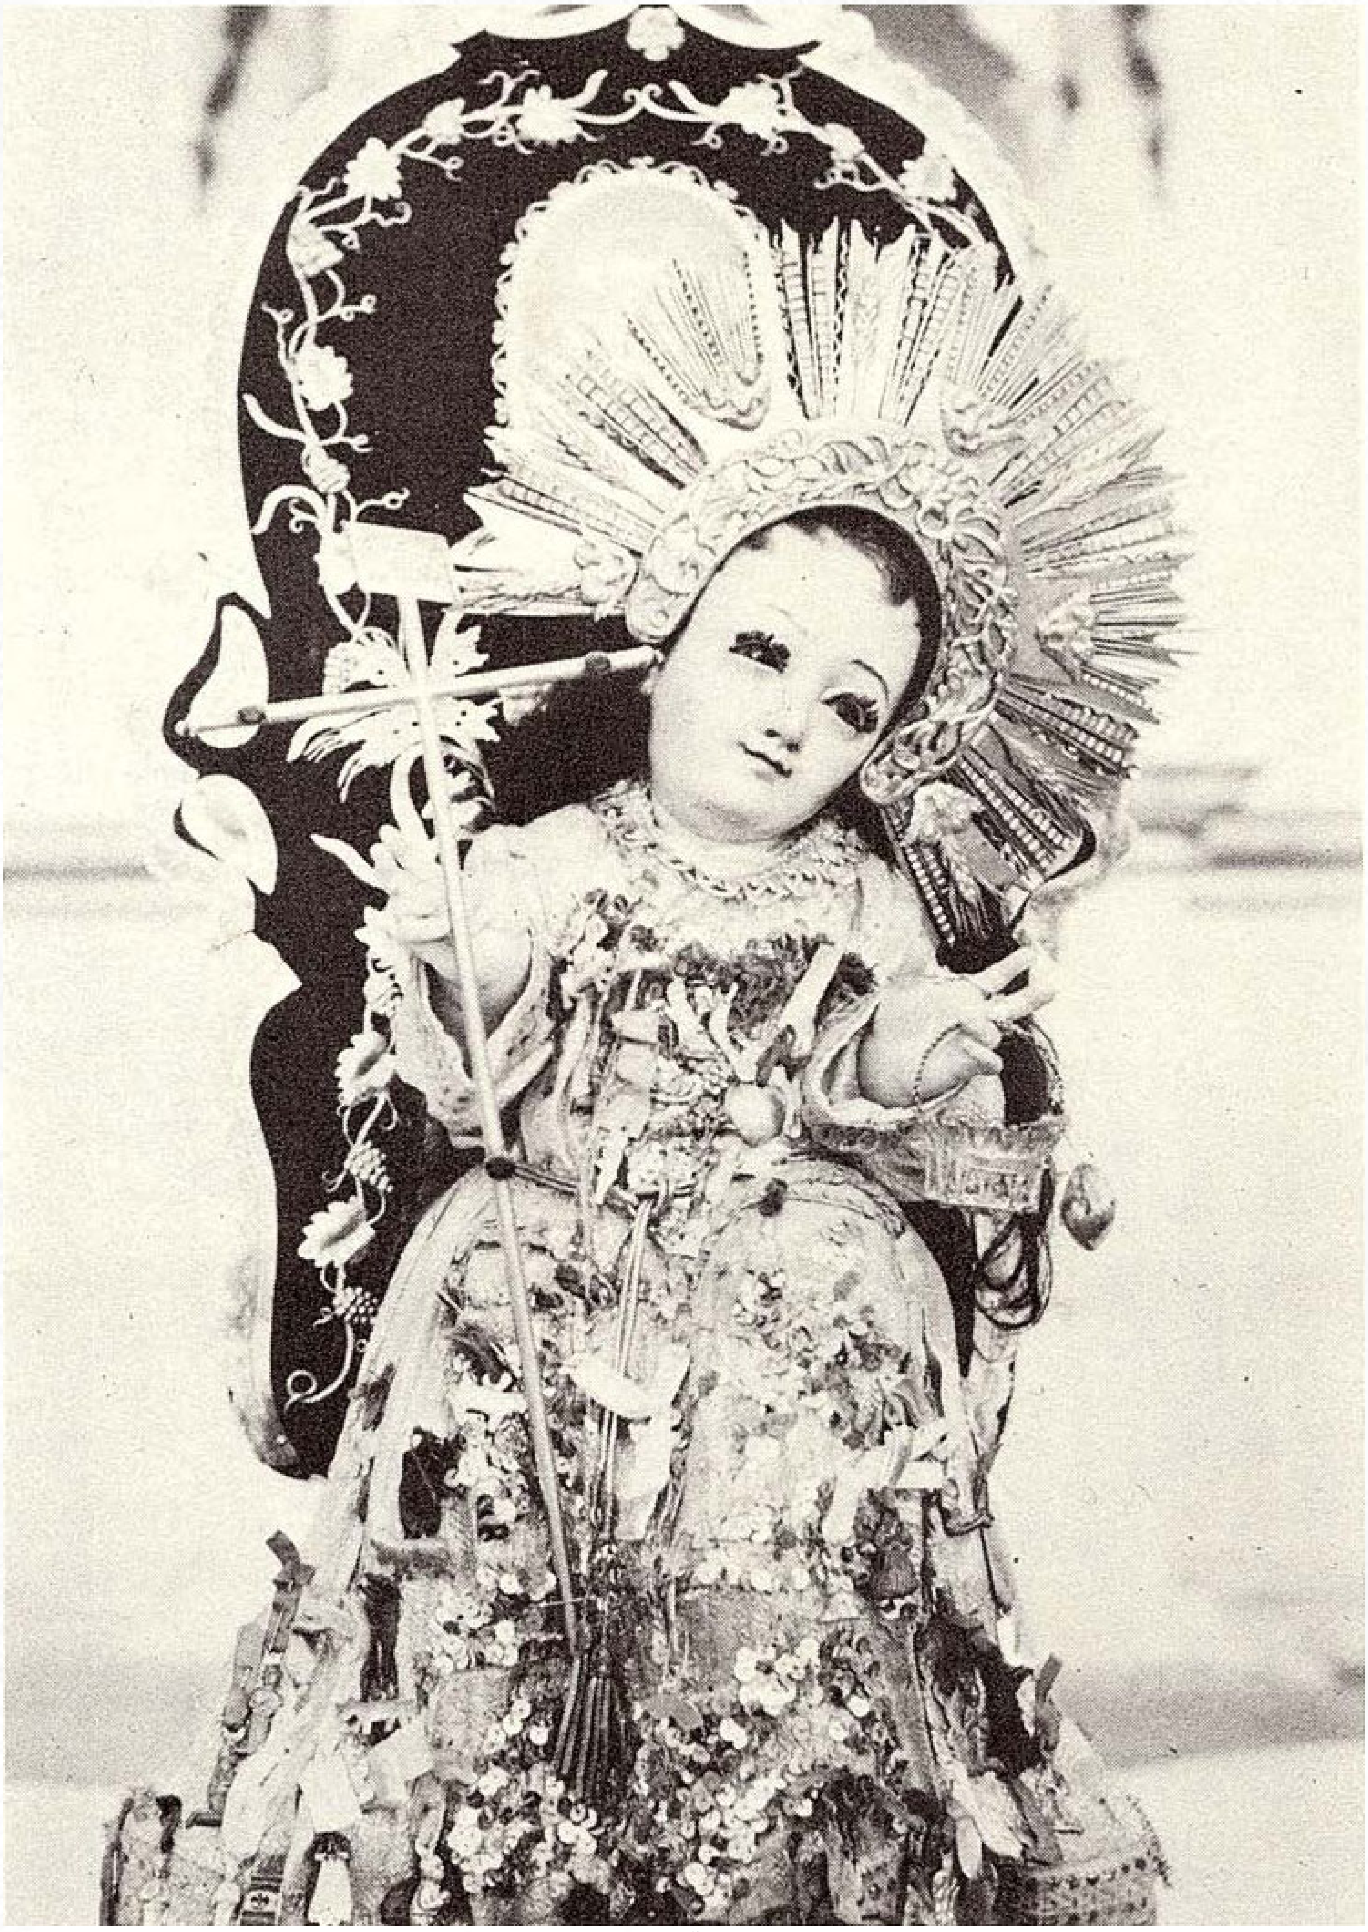

Fig 27 Santo Niño de Nundichi

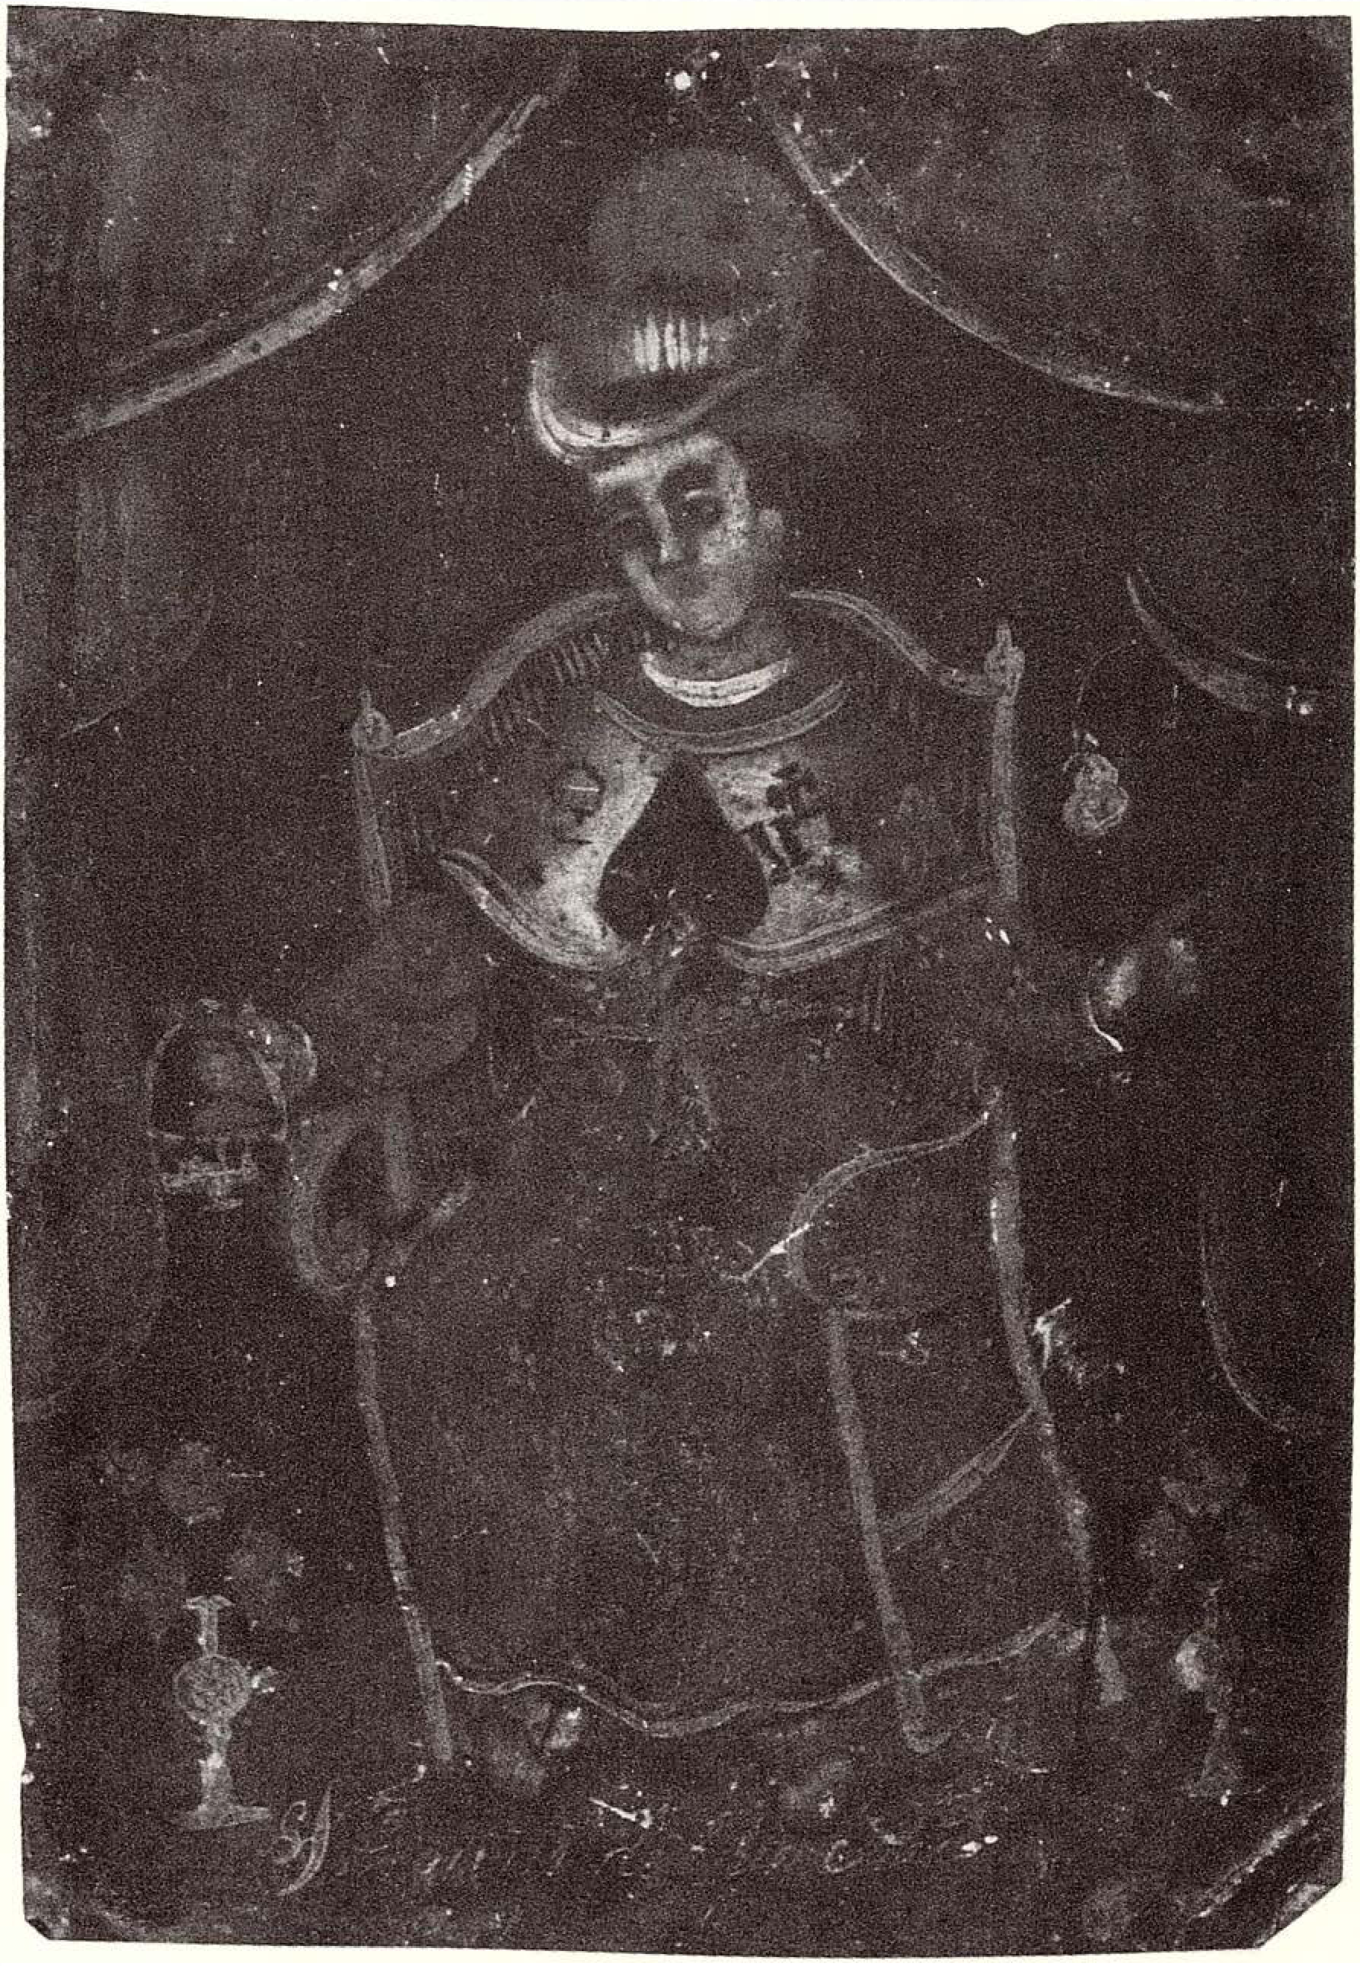

Fig 28 Santo Niño de Atocha, bought in the Flea Market in Mexico City

In San Juan Amatitlán, on the shores of Lake Amatitlán in Guatemala, we find also a famous cult of the *Santo Niño* in a church founded by the Dominicans. The day of the *Santo Niño* in Amatitlán is May 3.

In Huautla de Jiménez the parish church displays a *Santo Niño* in traditional style. Nearby, also in Mazatec country, in the village of San Mateo Eloxochitlán, not long ago, well within the memory of those still living, there was a *Santo Niño* who was an Indian child, barefooted, wearing breeches, a shirt with a check pattern, a sash, and a rosary. But one day, without consulting the parishioners, the priest replaced him with the effigy of the *Santo Niño* of Prague. The parishioners still speak with nostalgia of their former *Santo Niño* and express resentment at his kidnapping. In Tlacotepec on the road from Puebla to Tehuacán there is a Holy Child and in Puebla itself, in the Church of San Marcos, 2 January is set aside for the celebration of the Holy Child before his icon. Formerly he was *de bulto* also, but the figure disappeared during the religious persecution under Elías Calles, or so it is said. There must be churches without number in Mesoamerica where the cult of the Holy Child is a focus of devotion: I have cited only those that I know about along my routes in Mexico.

The pagan cult of Piltzintli still survives in the *rancherías* and villages where on altars in the humblest homes of monoglot Indians the traditional icon of the *Santo Niño* has the place of honor, a bouquet of flowers before him, perhaps a *vela* of virgin wax lighted in his honor, and from time to time a *velada* being sung all night by an hierophant to invoke his aid in the extremities of life. In these Indian homes lies the real focus of the cult of the *Santo Niño*, a cult of immemorial antiquity that is now fast dying out; here, not in Plateros nor in Amatitlán nor in Nundichi, where the acculturated worshippers have never heard of the Child God of the Mesoamerican Indians. In 1955, when I attended the *velada* sung by Aristeo Matías, in San Agustín Loxicha, a Zapotec village in the Sierra Costera, I was struck by his invocation in Zapotec of the *Santo Niño de Atocha* and in my field notes jotted down that observation. At the time I knew nothing about the *Santo Niño de Atocha* other than his name and did not link him with the entheogens. Today we possess the text translated into Spanish of three *veladas* sung by María Sabina in Huautla, one from 1956, another from 1958, and the third from 1970, the first two recorded by me and the third by a Mazatec at a *velada* where no outsider was present. In each of them, toward the end of the *velada*, she invoked the *Santo Niño de Atocha*. Many saints such as St Peter and St Paul enter into her singing repeatedly, as though she had recourse to them when her verses were running thin. But the *Santo Niño* occurs only once, near the end. For her as for Aristeo Matías, and doubtless for all other Mesoamerican shamans, the invocation is, I think, a structural feature of the pre-Conquest *velada*. Piltzintli - the 'Holy Childe' - was there from the start. He is there to this day, for all to see, as he dives down head first to the High Altar of Santa María Tonantzintla.

By divine grace we are given the supreme example in ecclesiastical architecture of the adoration of the *Santo Niño del Peyotl* (in its broadest sense) in the Church of Santa María Tonantzintla. In it the Christian and pagan elements achieve an harmonious blend. Here the little sprites, youths and maidens, are peopling the enchanted scene. Here there is no brutality - no Holy Office, no human sacrifice - only a garden that surpasses all dreams where mankind lives off the rich produce of the fields round about and on the entheogens of Mesoamerica, entheogens that the Greeks knew as ambrosia, the Aryans as *amrita*, the Siberian tribesmen as *pongo*. The Aryans used another word for their divine inebriant, *ándhas*, cognate with the Greek word for 'flower', ἄνθος, and both of them are the equivalent of the Nahuatl metaphor *xochitl*. The *veladas* of María Sabina and the inebriating world of Santa María Tonantzintla have led us to see with the eyes of Early Man a major aspect of his life that we did not know before, a vision of another world whose very existence remained almost hidden from us, a world surcharged with the vitality of youth and of incomparable beauty. In the fertile valley of Cholula religion meant much to the Indians before the Conquest and it suffuses their lives to this day. Here we find the answer to the theological enigma that Pedro Rojas put to us with extraordinary acumen: Piltzintli, the Master of Revels, the Holy Child, is plunging down to the altar where his mother the Virgin Mary is enthroned.

But let us go further. Is not this divinity the same as the plunging figure in the *Codex Borgia*, the *niño dios*, Piltzintli, that we display in Fig 29? Is he not the same that María Sabina had in mind, at an early point in her *velada*, when she asked me to vacate my seat because I would obstruct the descent of the divine spirit who was to arrive from above by way of the very corner that I occupied? (See p 13) There is a possibility that she speaks of the same divine epiphany in Chapter VI of the story of her life that Alvaro Estrada has given us. And what of the Diving God murals of Teotihuacán to which Arthur Miller draws our attention? Nor should we overlook one striking style of mushroom stone, from the Maya Highlands, of which we reproduce two examples on page 192. Are not these Maya effigies siblings to the plunging god of the *Codex Borgia*, of Santa María

Tonantzintla, of María Sabina's world? This *niño dios*, wherever we find him, is the god of the entheogen, is one aspect of Xochipilli.

CHAPTER 8

Teotihuacán and the wondrous mushroom

The meaning of the murals

In *Mushrooms Russia & History* (1957) Valentina Pavlovna and I set forth our reasons for thinking that certain details of the murals of Teotihuacán represented inebriating mushrooms. With one notable exception no Mesoamerican scholar has publicly commented on our discoveries although twenty years have elapsed and our findings elsewhere in Mexico have not gone unnoticed. The exception is Dr Alfonso Caso, who in his paper on the *Codex Vindobonensis* ratified our identification, specifying the murals that in this Chapter appear as Figures 1, 2, 7, and 12. His endorsement was unequivocal, although (as I have already pointed out) he dropped our mushrooms then and there. Apparently he felt that this theme, far from calling for further inquiry, was exhausted. Caso was like all other scholars in the Mesoamerican field: inhibited when dealing with the divine inebriants. Archæologists, the clergy, anthropologists, linguists - all touch them gingerly or not at all. They respond to my inquiries most courteously but on their own initiative do nothing. The exceptions are few.[29] It would seem as though there were a subconscious reluctance on the part of our Western society to recognize the rôle played in prehistory by entheogens.

I will now go further than we did in our 1957 book. Arthur G. Miller's *The Mural Painting of Teotihuacán* appeared in 1973. That ancient city, covering eight square miles in its heyday (ca AD 450-650), counted a population of at least 70,000 and perhaps up to 200,000, according to the careful study of R. Millon. In Miller's book, beautifully laid out, he gives a comprehensive survey of most of what had been discovered in the ruins up to the time of its publication: plans of the structures that had been excavated from the start of archæological inquiry about a century ago, photographs of their famous murals, black-and-white drawings to help the reader see in the photographs what the specialist sees in the murals, floor plans of the various edifices, and finally numerous and skillful repaintings of the murals by Felipe Dávalos G. to recapture the full effect on the worshippers of the originals when these were fresh. Anyone endowed with imagination is certain to be profoundly moved and also mystified by a school of sophisticated painting the like of which exists nowhere else in the world. One can see a kinship only with the art of the Maya and the codices of the Nahua and Mixtecs.

Miller plants squarely the basic questions. What was the purpose of the labyrinthine building complexes where the murals have been found? What was the meaning of the strange, the haunting Teotihuacán paintings? He does not hazard so much as a guess. He says no one knows. But in a fecund paragraph Miller draws attention to the often elaborate borders of the murals, with broad curvilinear and rectilinear bands braided together at intervals in sweeping rhythm (as he says) *that is almost musical*. And he adds:

> I do not mean to suggest that lines in Teotihuacán murals are recorded music, but I do suggest that they can have values which are musiclike *and may have been so to the Teotihuacános*.
> [Italics mine; Miller, p 29 col 1]

What astonishing perspicacity! Miller lacked only the key to the mystery. Here again in our inquiry we are finding the same missing clue: the Wondrous Mushroom.

The reader will recall how María Sabina in her *velada* intones chants that for the bemushroomed person assume rhythmic shapes, curving in and out of each other, and how the kaleidoscopic play of colors that the bemushroomed see in their visions pulsate with musical rhythm. The artists of Teotihuacán succeeded in conveying this sensation to Miller who knew not the mushrooms! (My impressions are paralleled by Henry

---

[29] The botanist Richard Evans Schultes and the anthropologist Weston La Barre among the older scholars have devoted much of their professional careers to the entheogens. Among the coming generation there has been promising initiative in various directions: Alvaro Estrada, Peter T. Furst, Michael Harner, Reid Kaplan, Henry Munn, Carl A. P. Ruck, and others. Many members of the Summer Institute of Linguistics have provided us with invaluable help, including Eunice V. Pike, George and Florence Cowan, Bill Upson, and Searle Hoogshagen.

Munn's, though he conveys them in utterly different language.) Miller speaks of the 'vibrantly colored shapes' of the murals of Teotihuacán, their 'intensity and vivid colors'. He cites Miguel Covarrubias who dwelt on their 'intensely religious' message, 'austere and distinguished, gay and graceful'. What a tribute to the ancient artists are these sensitive responses to their murals by acute observers who were ignorant of the entheogens!

Imagine then my astonishment when I found Miller saying that the 'disembodied eyes are important' both in the main composition and the border of a mural in the complex known as Zacuala.[30] Why was I astonished?

In my *Life* article, 13 May 1957, describing my own experience when I was bemushroomed in my first *velada* with María Sabina two years earlier, I wrote:

> There I was, poised in space, a *disembodied* eye, invisible, incorporeal, seeing not seen.

I had myself been the *disembodied* eye that Miller discovered some dozen years later in the murals of Teotihuacán painted a millennium and a half before!

Miller perceived the 'disembodied eyes' peopling the entire corpus of Teotihuacán painting, not merely in the Zacuala complex. When I wrote my *Life* article, Zacuala had not been excavated and Miller's book lay some sixteen years ahead. Miller did not remember my text: on the contrary, had he remembered it his text would have been utterly different. But had he even seen it?

In 1957 my knowledge of Teotihuacán was cursory. I had paid one visit to Teopancaxco and to the fragmentary murals of Tepantitla left *in situ*. (I did not see, much less take in, the 'disembodied eyes' in the lower register of the Paradise scene. Fig 12) Miller speaks of the 'disembodied eyes' mainly when he is discussing Zacuala, but, as many of his illustrations show, they permeate the murals of the city-sanctuary of Teotihuacán. The 'disembodied eyes' are the mushroom worshipper's eyes, whether open or shut, contemplating the scenes of another world, three dimensional, unearthly yet more real to the bemushroomed viewer than our world of everyday experience.

Miller was on the brink of discovering the answer to both his major questions: the purpose of the labyrinthine building complexes and the meaning of the Teotihuacán paintings. Neither in his text nor in his captions nor in his bibliography does he cite any of our writings, which have been numerous and circulate widely, nor Roger Heim's, equally numerous, nor (somewhat later) Peter T. Furst's and others'. He speaks in a caption of a personal communication from Furst in 1971 identifying certain flowers in the paintings as morning-glories but fails to explain to his readers the meaning here of morning-glories. He is certainly not at home in botanical iconography nor the entheogens.

My thesis is simple. For centuries Teotihuacán was a vast sanctuary dedicated to the two or three hallucinogens that enjoyed superlative prestige. What we have been calling the building complexes were simply groups of cenacula where small gatherings of pilgrims would assemble to consult the entheogen under the direction of one or two or more hierophants. The number and elaboration of the building complexes speak for the ritual activity that went on over centuries at Teotihuacán. Pilgrims came from near and far. The permanent population of hierophants and their families, augmented by the host of personnel needed to provide services for the pilgrims, accounts for the 70,000 that R. Millon puts as his minimum figure, and the transitory pilgrims may have occasionally pushed that figure as high as 200,000. There were the rudimentary hostels to house and feed the pilgrims: their needs were simple. There must also have been a mechanism to pay in kind for board and lodging, for the services of the hierophants, for the use of a chamber, and for the consumption of the holy elements of the divine office - the mushrooms or morning-glory seeds, copal, cacao for drinking with dried *poyomatli* flowers, guacamaya feathers, *pisiete* with lime, perhaps turkey eggs. I should suppose the hierophants were recruited from the various linguistic groups of Mesoamerica and if so, the pilgrims might then choose one from his own country, even his own village, possibly a kinsman. After dark on the appointed night the pilgrims would make their way to the building complex where they were expected: the thoroughfares were narrow, but there was no need for wider passages as there were no horses nor hand-drawn 'rickshaws'. Carrying flares (properly speaking, 'links'), the little company of pilgrims, on arriving at their building complex, would be guided through the passageways, sometimes along lengthy corridors, where by their flickering lights they would see murals of hierophants, in their impressive vestments, until finally they would arrive at the cenaculum where they were expected.

---

[30] Miller p 29 col 2, p 23 col 1.

The chambers were small after the layout of Cayetano García's, suggesting rather a group confessional than a vast church or temple. The murals on the walls were painted in flat two-dimensional colors devoid of perspective, as Miller's book shows us, the hierophants in their vestments more or less as in our Figure 2. Each chamber had its own band of suppliants, perhaps hailing from the same neighborhood. The worshippers, often after days of walking, would finally arrive, keyed to the highest state of expectancy, at the appointed cenaculum. The vast amphitheater of Teotihuacán supplied the noblest of settings and the celebrants were masters of their craft - greeting the worshippers, asking each what problem preoccupied him, administering the mushrooms (or infusion of morning-glory seeds), ushering in the period of silence and darkness while the entheogen took over the company. In Teotihuacán the celebration of the sacrament must have been a model of excellence, the liturgy being elaborated with all sorts of subtleties and refinements: the superb vestments and masks of the celebrants, their bearing and gestures, their voices beautifully trained.

Before the lights were extinguished the murals and the celebrants were the last visual impressions. As the entheogens took effect, the next sights the pilgrims saw, in the dark, eyes open or closed, were the murals springing to three-dimensional life, far more real than what they knew from the workaday world. Then they heard the chants intoned by the celebrants, the percussive beat of the small drum, the sounds being tempered to the small room, subtly played in syncopation, the sights and sounds being bathed in the fragrance of burning copal, of *poyomatli*, of other aromatic herbs, the sounds coming ventriloquistically, from suddenly shifting directions, in suddenly shifting volume, the whole blending inextricably into one harmonious sensation uniting sight, sound, fragrance. At that moment in the night when the entheogens reach their peak effect, then would come the oracular utterances of the hierophant, sweating profusely, perhaps having inhaled draughts of tobacco smoke, in response to the specific problems preoccupying the individual worshippers, each verse ending with 'so says the mushroom', just as I have heard it in Huautla.

All this is gone now: all that is left are what remain of the murals of Teotihuacán rendered by Miller in his noble book and the chanting of shamans like María Sabina. We know that her chants are of immense antiquity and they may well preserve the melodies and even the meaning of the words of the hierophants of Teotihuacán.

Were the Teotihuacán paintings, or some of them, executed while the painter was under the influence of the entheogen? They tell us vividly what the Mesoamerican saw and sensed when he was bemushroomed. They are done with such disciplined control that one would think they must have been accomplished by sober artists working in the full flood of their immediate memories. But this may be a Western point of view: the discipline that the bemushroomed acquires with practice is a marvel, and the artist (himself a hierophant?) may have prided himself on having painted them under the immediate dictation of the entheogen.

There was no vast edifice for corporate worship in Teotihuacán, no 'cathedral' or 'temple'. If there was human sacrifice, this was performed in the open, atop either of the two pyramids, the one to the sun and the other to the moon. These pyramids antedated by centuries the time of which we are speaking, and the cathedral of Teotihuacán was truly these pyramids set against the heavenly panorama of the hills and sky encircling the vast theater of that wondrous sanctuary.

I am sorry Arthur Miller did not know our writings for he would then have answered his own questions and rounded out his impressive work. By an heroic feat of disciplined imagination an occasional Mesoamerican scholar with the soul of a poet might be able to enjoy the shadow of a *velada* without ingesting entheogens. But why make this effort? For most there is no substitute for the real thing. The day is arrived when no one who would learn what Mesoamerican culture meant to the Mesoamericans, what the murals of Teotihuacán meant, what the picture writing of the codices meant, what the surviving Nahuatl poetry meant, what the intoning of the chants meant - that is to say, no aspiring Mesoamerican scholar - will deny to himself *the* key to this understanding.

Teopancaxco and the water glyphs

One of the earliest murals of Teotihuacán to become known, in the late 1880's, is in a chamber - a cenaculum, as I believe - of a structure called Teopancaxco. On one wall of this small chamber is a mural painting that we reproduce in our Fig 2. There can be no doubt that its reconstruction by Agustín Villagra Caleti conveys the effect of the original mural. Damage through the centuries and neglect since it was rediscovered had taken their toll. In our reproduction the darker field shows the portions that were well preserved when Villagra undertook his task, and he also had access to paintings of other hierophants in procession. Almost all of the border had disappeared, and of the murals that had originally covered the other three walls there was virtually nothing left. When we visited Teopancaxco in the middle fifties we noticed, on the wall to the right as one faced the surviving mural, a small stretch of the original border (including an angle) of the lost mural of that wall. Though many must have seen it, no one had yet copied it. At our request Eduardo Noguera took the task in hand and gave the commission to Villagra. This border fragment will be found in Fig 1, and as that portion of the mural is an authentic Teotihuacán painting, in no way retouched, it serves well to demonstrate my thesis. We discover here the glyph for water in Mesoamerica at an earlier stage of its pictographic evolution.

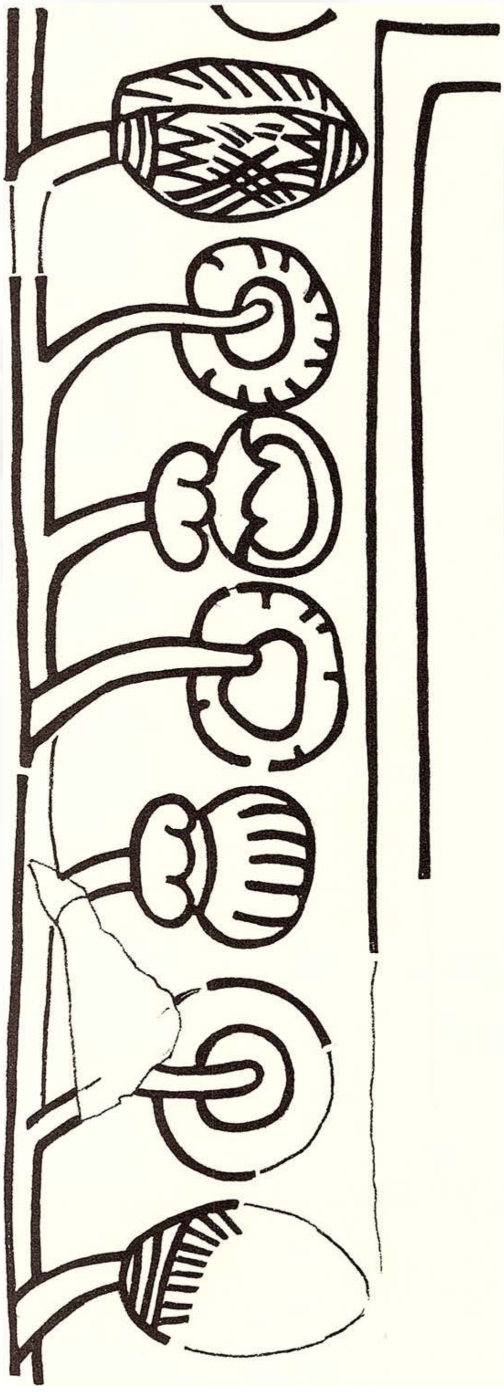

Fig 1 Teopancaxco mural. Detail, reduced

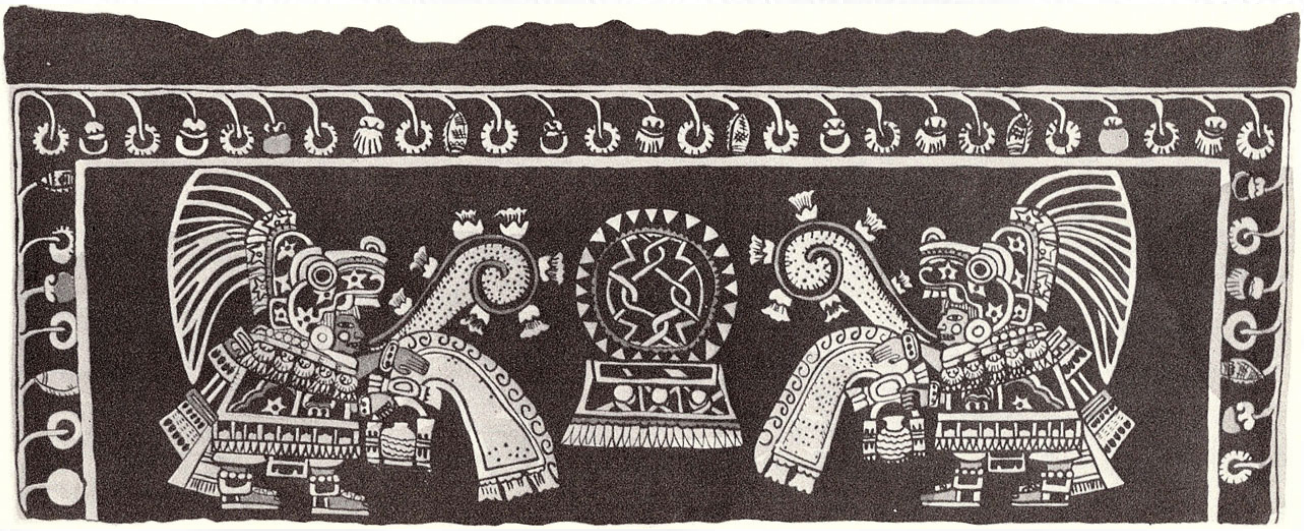

Fig 2 Teopancaxco mural. Teotihuacán, in the Valley of Mexico. From Teotihuacán III Period, AD 300-600

Working down from the top, first we find a well delineated marine snail. I think no one has ever disputed this identification. Next comes what is for me plainly the undersurface of the cap ('pileus') of a mushroom showing the gills ('lamellæ'). The stem ('stipe') emerges from the center of the cap and runs like an umbilical cord to a stream of water, the waters of life, the waters that one links inevitably with shells and mushrooms. In the mural itself there survived the faintest traces of green paint on the mushrooms, signifying holiness. As for the third and fifth glyphs, prevailing opinion is that they are bivalves, but in the glyph for water do they ever recur in Mexico? The murals of Teotihuacán are clearly the product of a long evolution in picture writing of which no one has yet found examples, and these two 'shells' may well have been obsolescent elements in the water glyph. The marine snail, however, often accompanies the mushroom, even in post-Conquest times, as we saw in the pictogram for water in the mid-sixteenth century *Códice indígena* No 27, p 110. But the mushroom is always present, simplified, reduced finally to two concentric circles or even to a circle around a dot. The overwhelming importance of the divine mushroom in pre-Conquest Mesoamerica finds fitting expression here in the link between water and mushroom, in the glyph for water, in a glyph that sanctifies water by tying it to the divine *flower*, a *flower* that is green for holiness.

Alfonso Caso accepted our identification of the symbol as a mushroom, and I think this is hard to challenge. Why should it not be the mushroom that plays so big a rôle in Mesoamerica? Some have suggested in conversation that it might be the leaf of a water-lily. But the water-lily, as we see in Fig 3, has a deep cleft where the stem leads off and the veins of the leaf assemble. The water-lily belongs to the genus Nymphæa and all species of that genus have the cleft leaf. A pictographic artist catches the significant lines of the model. Those lines persist through generations and no artist portraying the water-lily could miss the distinctive cleft. What the artist does catch are the radiating gills of the entheogenic mushroom around a blank center where the round stipe is reduced to a circle. How different would be the veins in the water-lily leaf gaining strength as they assemble at the point where the stem leads off! Some ask why the 'mushroom' could not be a flower or seashell, but they do not suggest the species and are idly guessing. Why is there this reluctance to recognize the Wondrous Mushroom when the pictogram is so consistently displayed? A survival of the age-old mycophobic syndrome?

Every pictogram has its origin in a specific object and here we have the sacred mushroom. Much later, when his reading clientèle had become used to the lines, the scribe simplifies them until at last the lines are so abbreviated as to make the glyph obscure for the outsider. At Teopancaxco we possess a pictographic artist's work when the mushroom was still easy to recognize. In the evolution of the pictogram the stipe disappears, leaving a round inner ring, and the gills disappear, leaving the outer ring. The two rings persist to the end, but the inner one is sometimes reduced to a dot, as we saw in *Códice indígena* No 27, p 110.

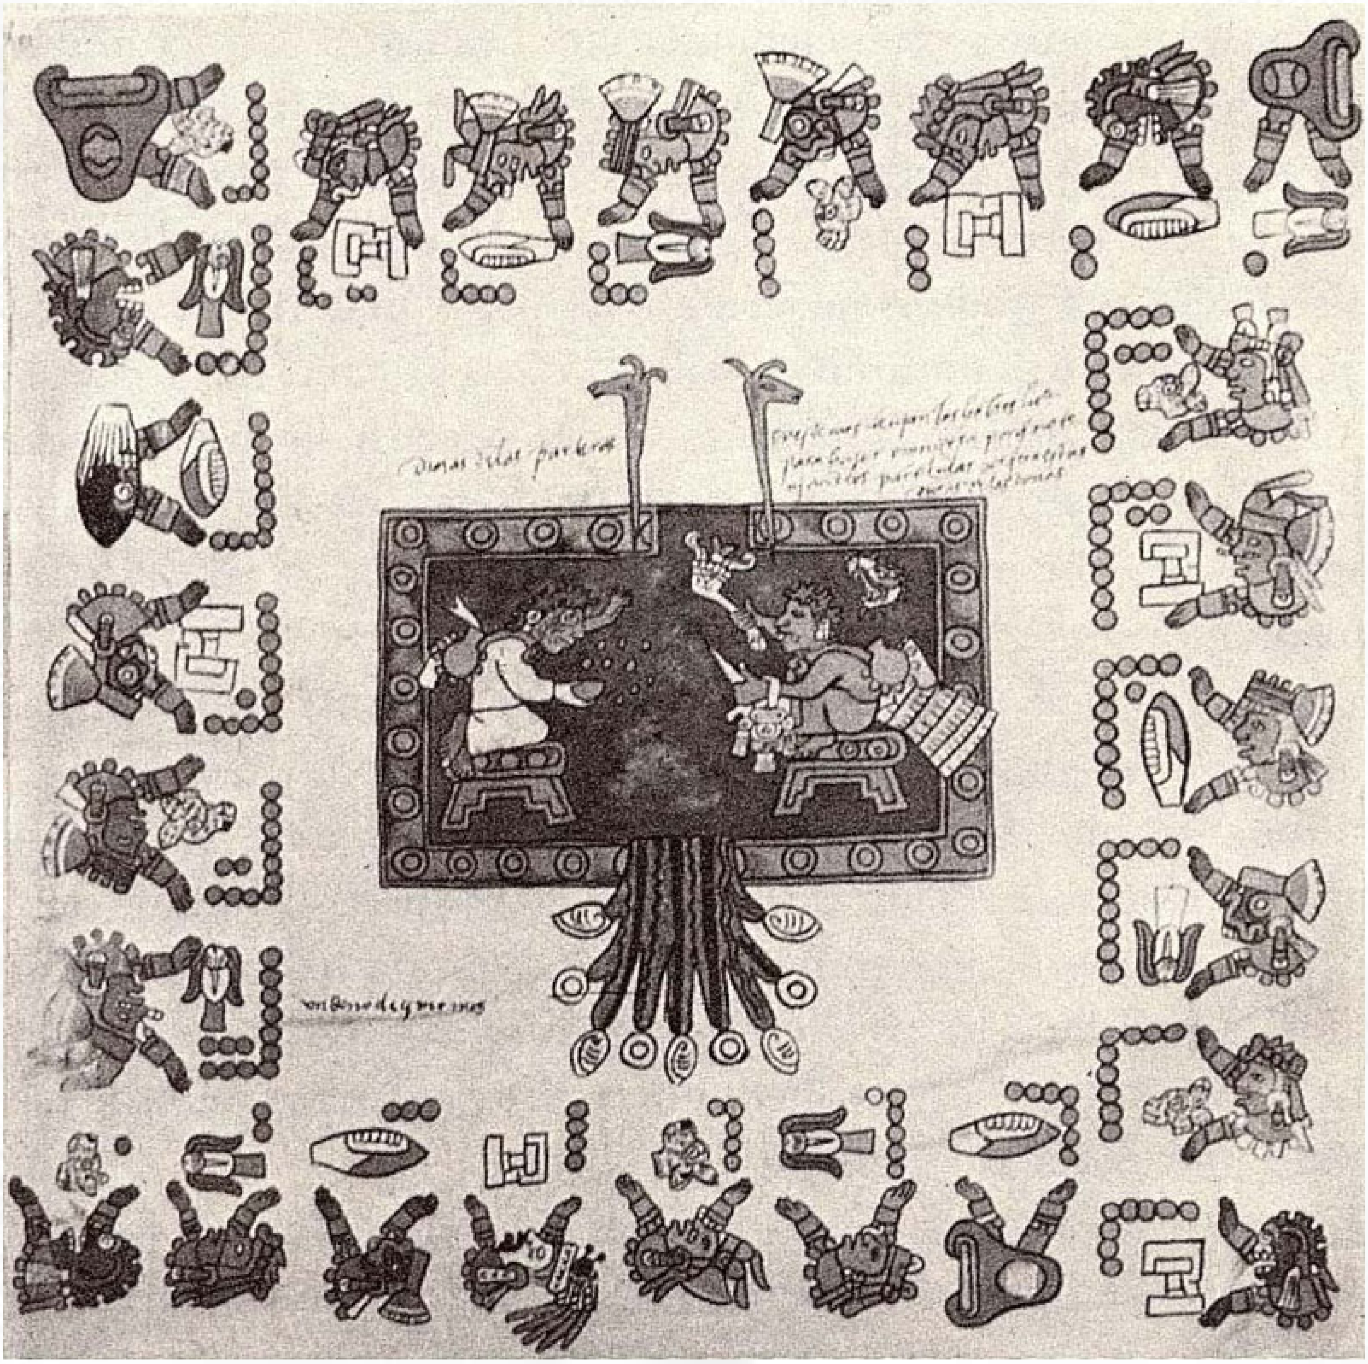

Fig 5 *Codex Borbonicus*: Two Ancients

Why did the hierophants and pilgrims stress seashells in their murals? The sea is hundreds of miles from Teotihuacán. There seem to be no midden heaps in the ruins of that ancient city. Perhaps the pilgrims took shells back home as a lasting souvenir of their pilgrimage. But such a practice would be a by-product of the main use, and might relate only to the elaborate and beautifully structured shells that are frequently seen in many of the Teotihuacán murals. The main use would be different: lime, ground fine, is mixed with *Nicotiana rustica* to make the bright green *pisiete*, widely used in Mesoamerica for rubbing on the body in healing rites and often held as a wad in the cheek. The shells may have supplied lime for adding to *pisiete*. Lime was naturally available close at hand but to get lime from either sea - Pacific or Caribbean - from the clean pure shells in their amazing and endless shapes, abundantly illustrated in the murals of Teotihuacán, would be a telling refinement in the entheogenic rite. No honor was too great for the sacred mushrooms or morning-glory seeds.

In the surviving mural of Teopancaxco two hierophants are facing each other and chanting. Their singing scrolls are adorned with *flowers*. We assume that they are bemushroomed and chanting to a tiny band of suppliants also enjoying their 'dream flowers', *temicxoch*. They are pouring a libation including seeds on the ground but what it is we do not know. With our Western fixation on alcohol, some have said it was pulque. On excellent authorities, contemporary and historical, alcoholic inebriants and the divine inebriants were not mixed and the hierophants were certainly not under the influence of alcohol.

Skipping now forward a thousand years, let us look at a few instances of the water glyph in pre- and post-Conquest codices, where the examples are innumerable. In Figure 4 we show a representation of Tlaloc, the god of rain, taken from the pre-Conquest *Codex Borbonicus*. The water with which he is identified carries our glyph repeatedly, shell and mushroom alternating at the end of the streamers leading to the flowing water. In Figure 5, again from the *Codex Borbonicus*, two ancients are casting kernels of grain in a cave from which a stream emerges, the stream being similarly identified by shell and mushroom. Our third, Figure 6, is post-Conquest, in the *Atlas* of Diego Durán. It shows the founding of Tenochtitlan-Mexico City, and the lake where the city was built carries on its edges the glyph now reduced to nine 'mushrooms', insignificant in size, but seemingly necessary; the shell has vanished. The mushrooms in these codices no longer wear the color green. In the post-Conquest *Códice indígena* No 27 (p 111) we follow the evolution of the glyph for water from (1) the shell-and-concentric circles to (2) the concentric circles alone, and finally to (3) a mere dot in the center of a little circle.

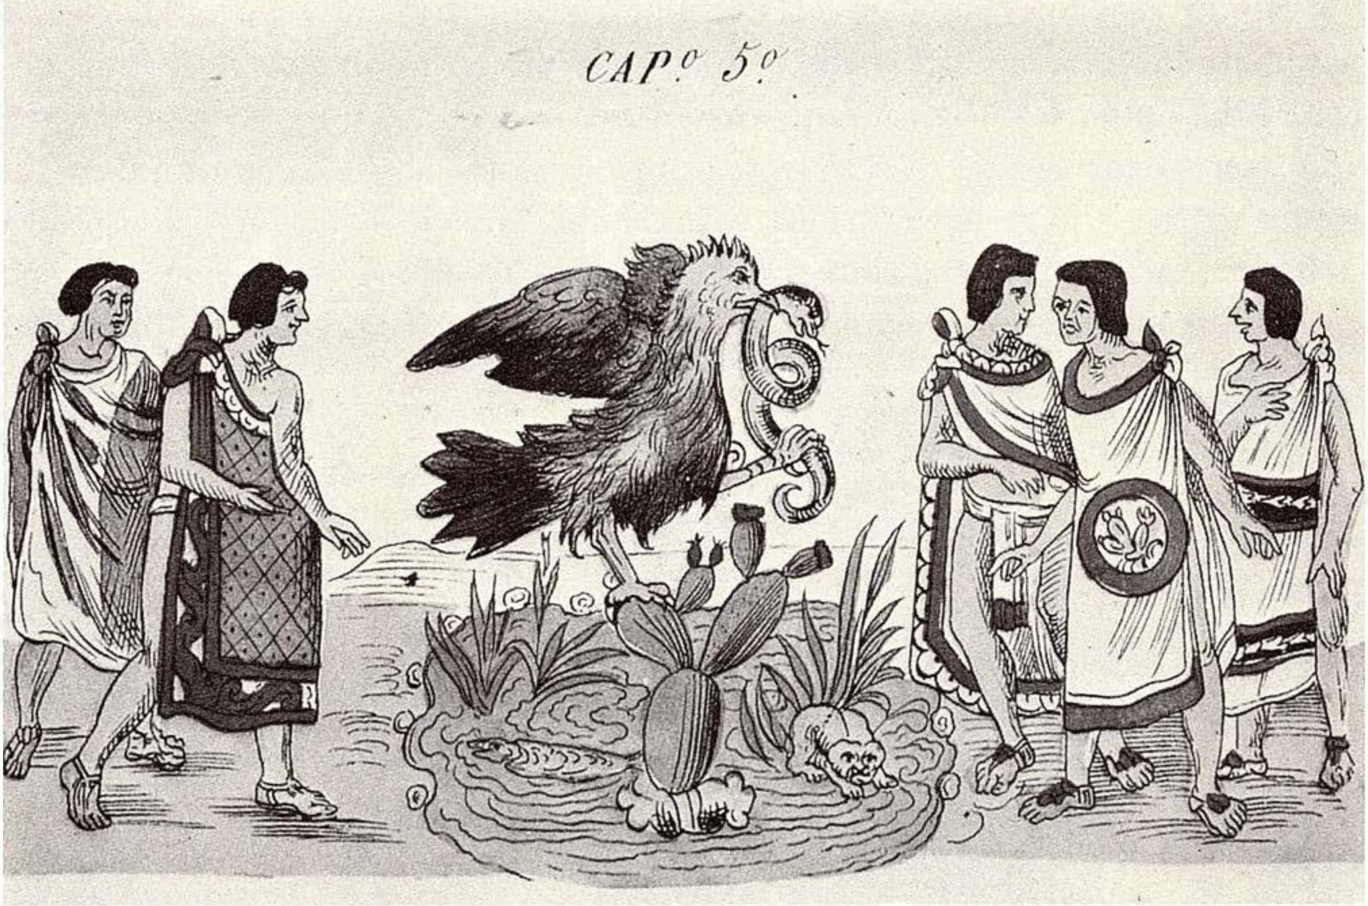

Fig 6 Diego Durán: Founding of Tenochtitlan (Mexico City)

Tepantitla

Perhaps the best known of the murals of Teotihuacán are those of the building complex called Tepantitla, restored by Agustín Villagra Caleti, now displayed for all to see on a wall of the Museo Nacional de Arqueología in Mexico City. The word 'restoration' calls for a word of explanation. When Mexican murals some 1500 years old are discovered, they are never in prime condition. At best the colors are faded beyond the layman's understanding, and the lines are obscure. It takes long experience to read the lines and colors. In those murals that lend themselves to restoration, the specialists familiar with the colors that the ancient painters had at their command can often say precisely which colors were used. By minute inspection they can read the original outlines and also the colors of what survives and give us again the artist's intention. There lies the duty of the restorer and beyond that limit, if he is a good restorer, he will not go. Villagra is an experienced, conscientious painter who does not invent motifs: here is the verdict of outside judges who have minutely examined his work at Teotihuacán. He makes the murals live again for us in the colors close to or perhaps the same as the pilgrims in A D 500 saw. His restoration of Tepantitla took place almost twenty years before our 'hallucinogenic mushrooms' came to be discussed.

Some years ago Dr Efrén del Pozo and I visited Villagra in his studio-home. Sr Villagra was glad to show us the stages of his restoration of Tepantitla, a series of draft-studies that he had made immediately after the archæologists had uncovered the originals. (The murals, when exposed once again to daylight and the atmosphere, deteriorate rapidly.) In the upper register of the main mural of Tepantitla there is the massive divinity that George Kubler, Peter Furst, and others take to be female (Fig 7) and above her head is the 'Tree-in-*Flower*', a 'tree' painted in Teotihuacán perhaps fifteen hundred years ago, which Diego Durán describes when he tells us of the celebration of the Feast of Xochipilli and which we link to the texts of Nahuatl poetry given us by Father Garibay. It is a 'tree' made *ad hoc*, not a living tree. This interpretation seems to be the consensus of informed belief today. Dr del Pozo photographed some of Sr Villagra's early drafts and we reproduce them in Figures 8-11, showing something of the many stages by which he arrived at his 'Tree-in-*Flower*'. First he restores the patches where colors and lines are unmistakable. He studies those lines and colors and extends them, helped by vestiges and by the artist's grasp of the original artist's conception. Where there is nothing left, he leaves nothing.

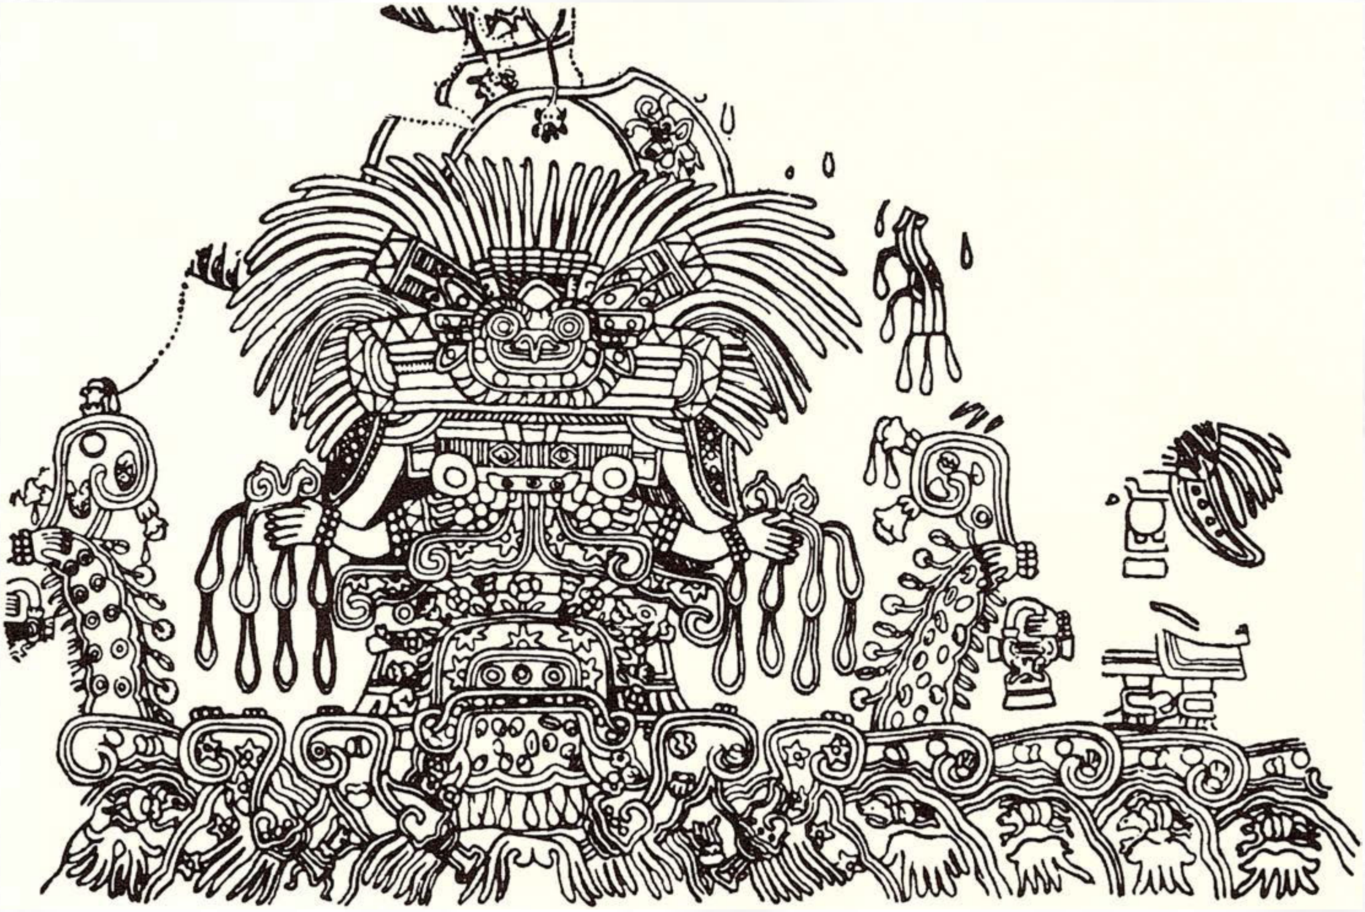

Fig 7 Female Divinity, Tepantitla

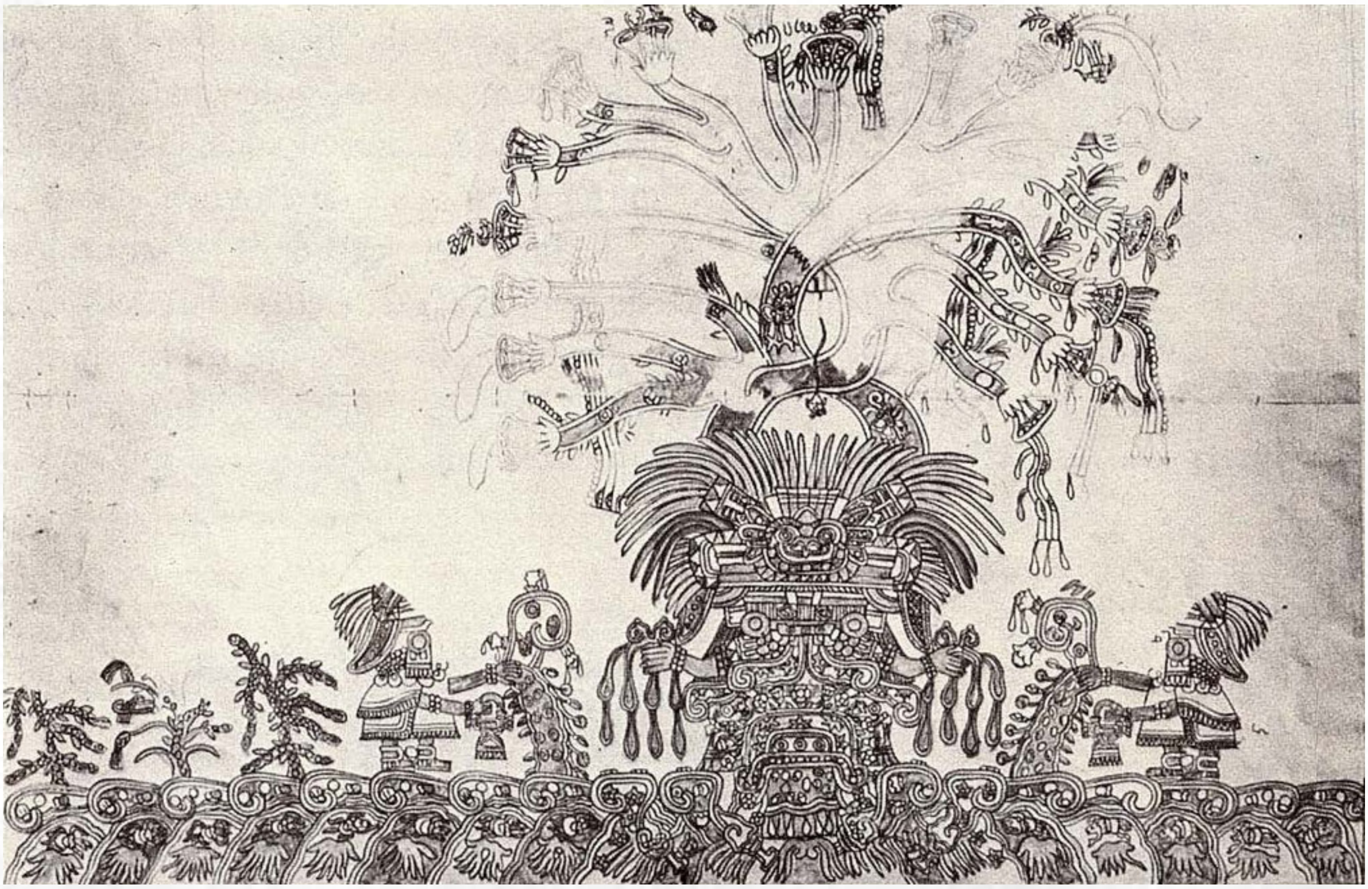
To the right of the divinity, a hand of a lost hierophant or deity protrudes and from it gushes a stream of falling water. (Fig 10) That this is indeed water is proved by the glyph to which we are now accustomed, alternating shells and mushrooms. The mushrooms are green. In the stream itself are seeds among which I recognize entheogenic seeds of Rhynchosia sp.



Figs 8-11 Villagra's intermediate paintings after a Tepantitla mural and details thereof

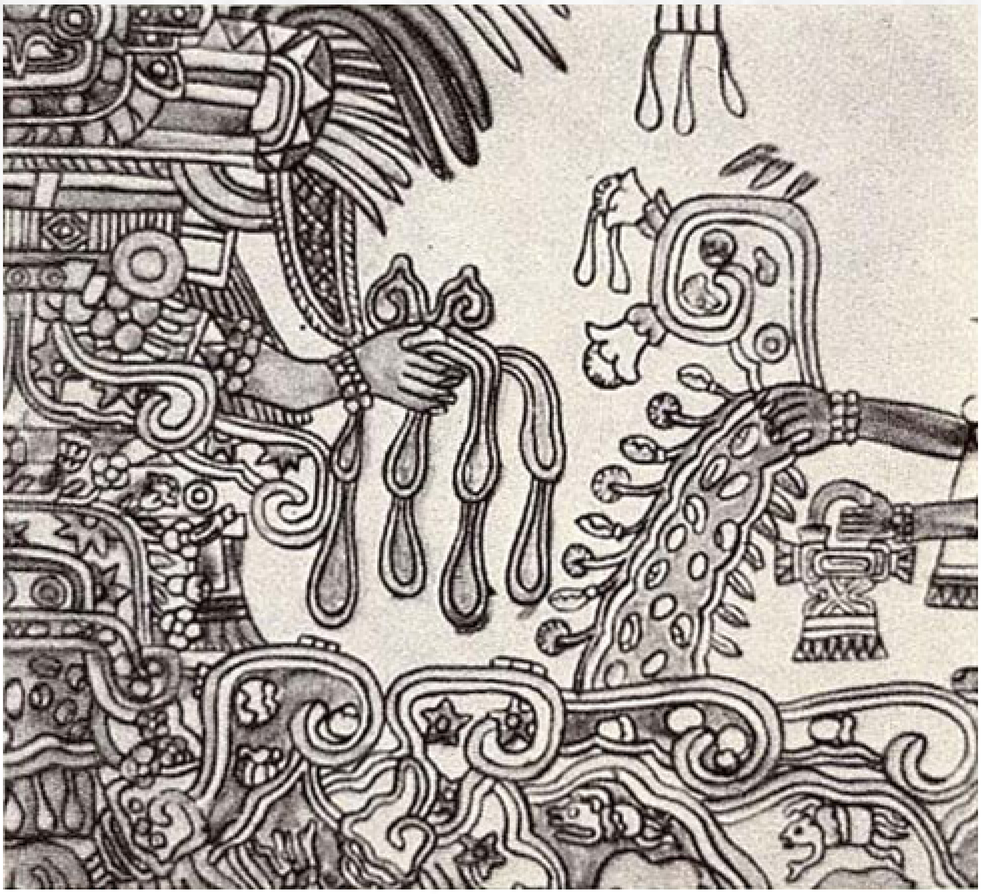


Fig 9

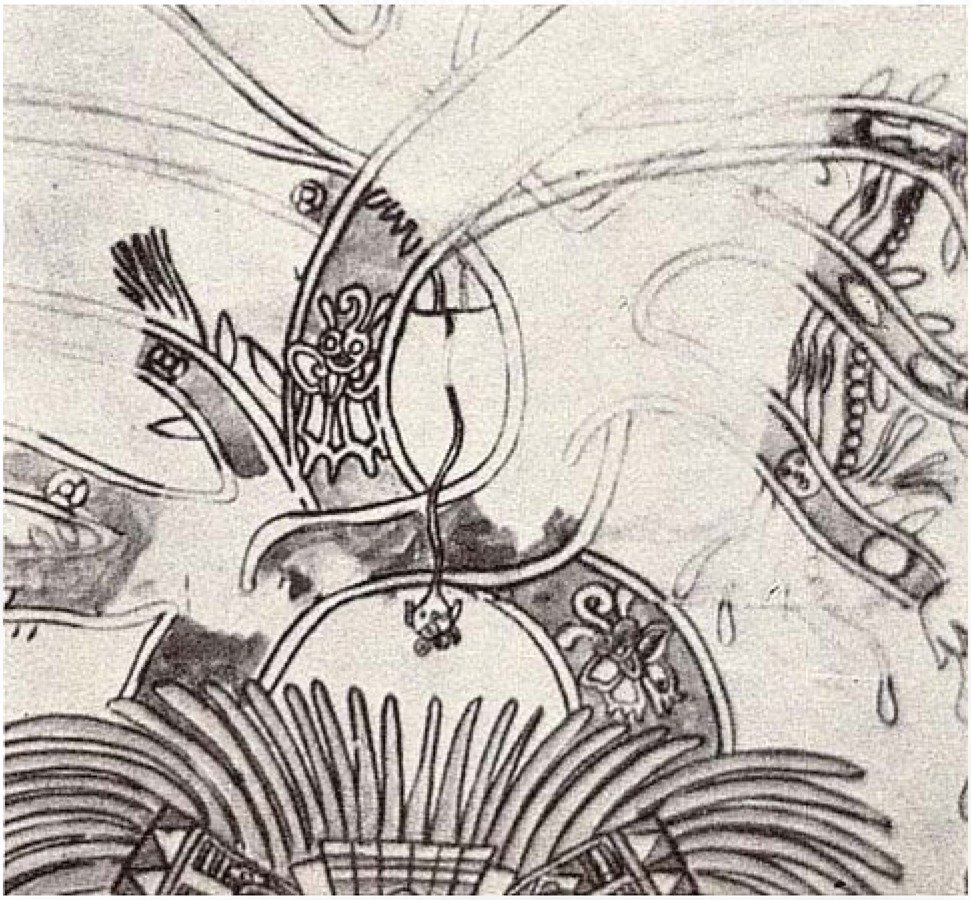

Fig 10

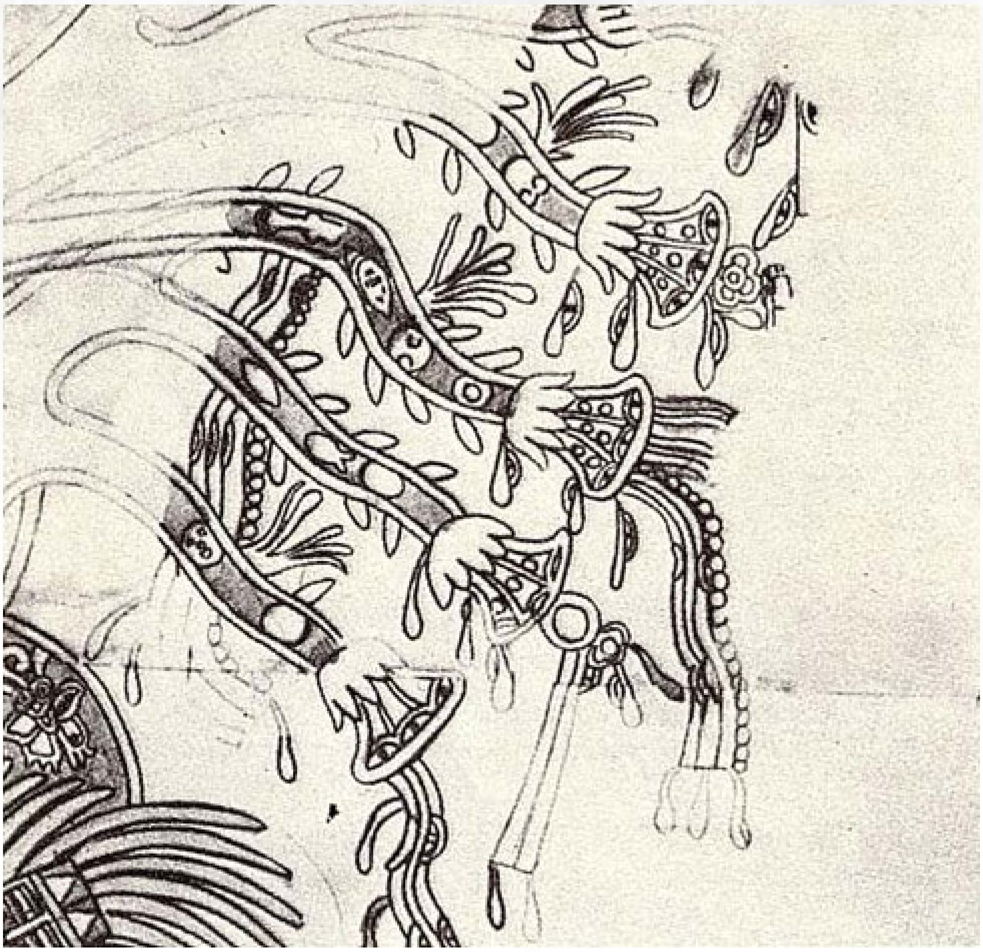

Fig 11

In the lower register of this mural we see the 'Playing Fields of Paradise' or Tlalocan as Caso has suggested. The lower right-hand corner of this mural shows a newcomer arriving in Tlalocan, waving a branch and shedding tears of nostalgia: so they interpret the picture. He sings an elaborate canticle, with five turnings in his speech scroll ornamented with *flowers*. Underneath this scene a stream emerges from the mouth of a frog. In the lake where he squats we see three times the symbol for water - shell and mushroom - and as the stream courses along 'disembodied eyes' mark its path. The whole scene is of the real world of the entheogenic vision of the Mesoamericans (Fig 12), unsuspected by Dr Caso or Sr Villagra.

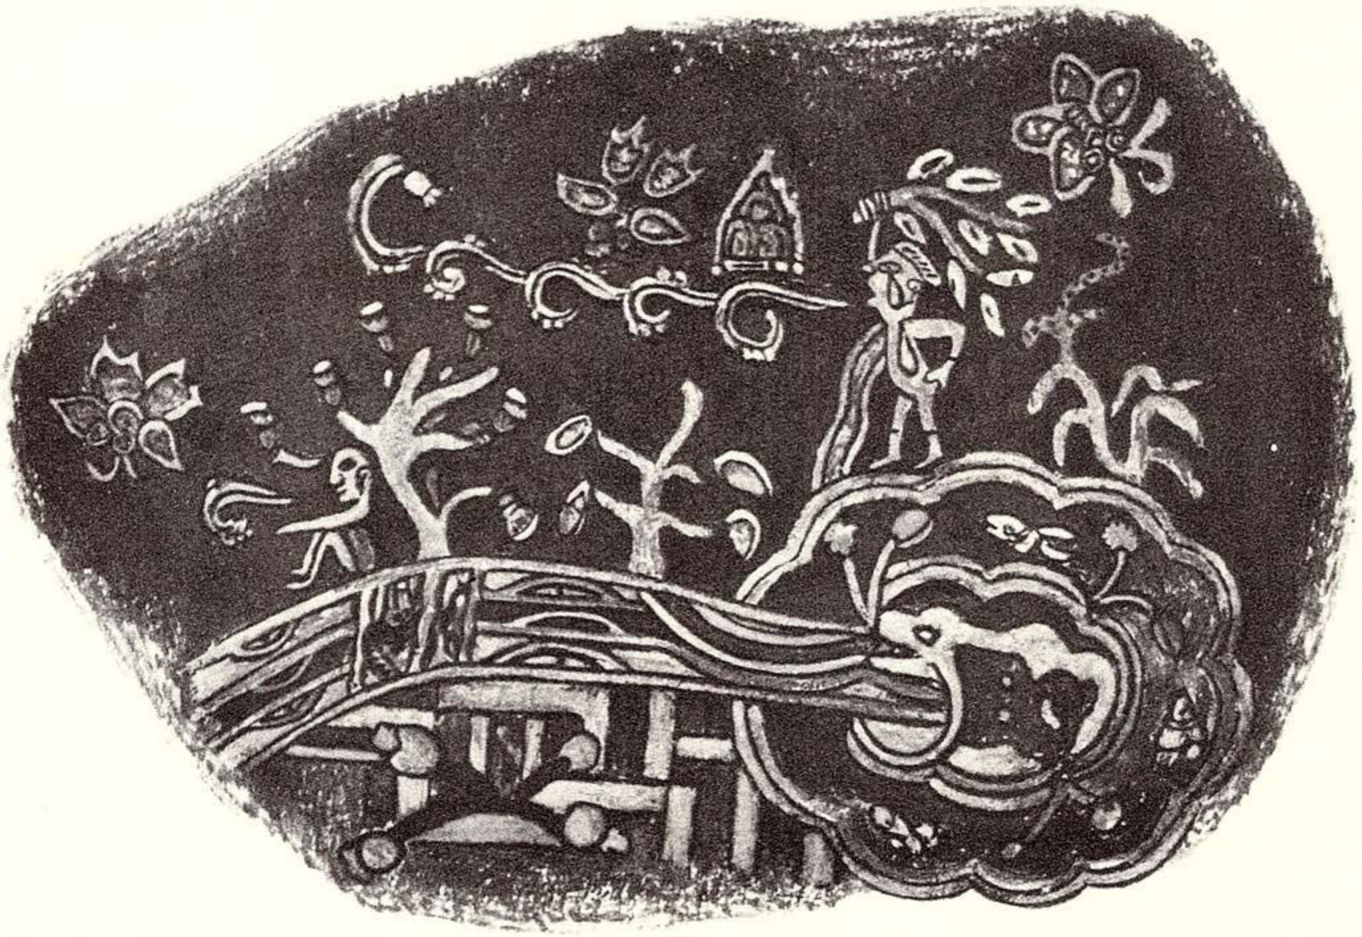

Fig 12 Tepantitla mural, detail: soul arriving on the Playing Fields of Paradise

Dr Henry B. Nicholson also photographed for me a few details in the borders, often serpentine, of the Tepantitla murals. We show these in Figures 13-15. From a jaguar's mouth hangs a mushroom, green for holiness, and from the top of his head bursts forth a fountain, dividing into two streams that fall on each side of his face. Drops of fluid, obviously entheogenic, emerge from the streams and a score or more of 'disembodied eyes' attend their fall. Nicholson gives us also another detail showing strange aquatic figures swimming with the familiar water glyph in their mouths - shell-and-mushroom. In a further detail there is the mushroom flanked on each side by a shell, the shells being of different species.

Margaret Seeler has supplied me with four black-and-white reproductions of the Teotihuacán murals that appear here as Figures 16-19. In two, *flowers* (perhaps highly stylized morning-glories) drip wondrous fluid, the flowers and the drops being accompanied by 'disembodied eyes'. In another, three creatures are proceeding upstream each with a mushroom in its mouth - a flying fish, a turtle(?), and a heron. Especially striking is the fourth: drops of fluid, obviously hallucinogenic, are giving birth to 'disembodied eyes' as they fall.

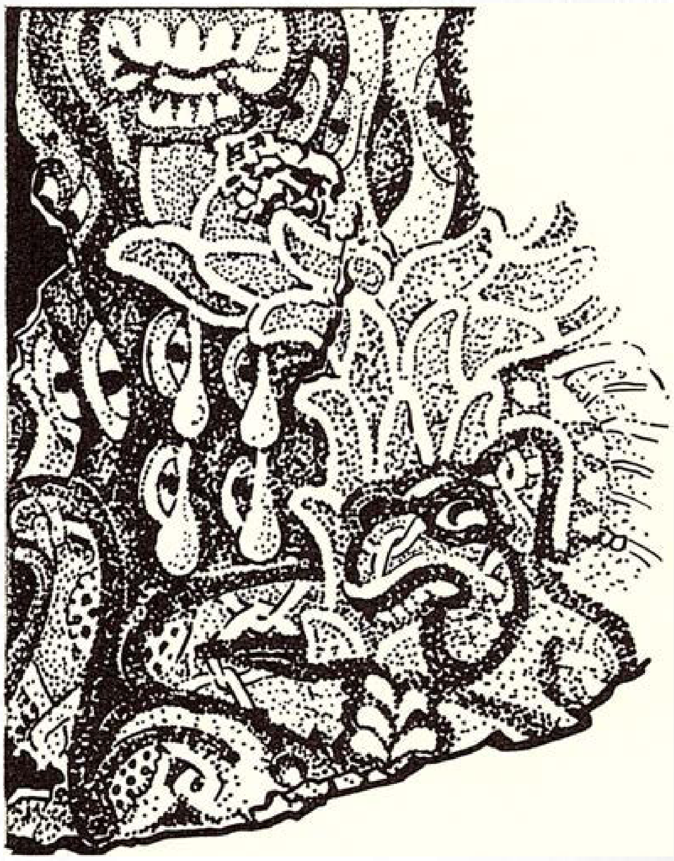

Fig 18

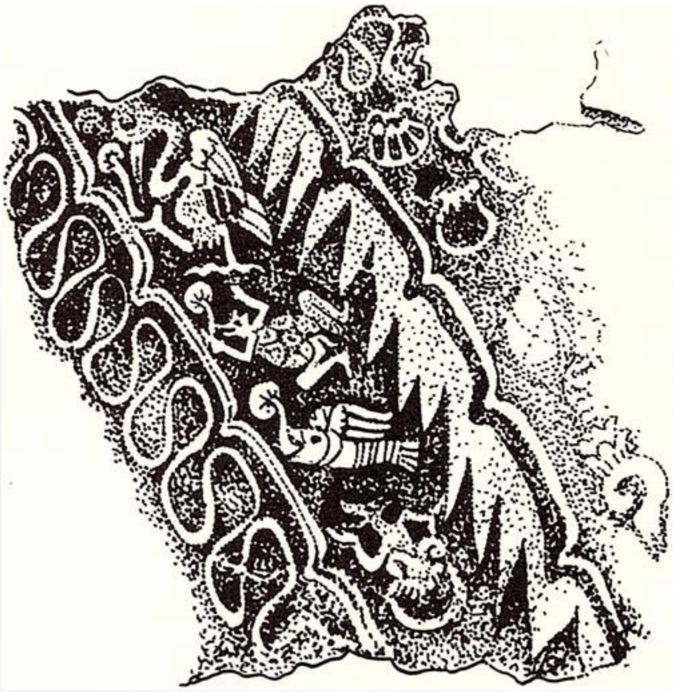

Fig 19

Zacuala

In all the glyphs for water that we have seen, mushrooms were the telling ingredient. But mushrooms figure also in isolation, away from water. Mme Laurette Séjourné and her archæological team discovered a mural on the front, perpendicular part of a step (it might be called a 'predella' in Western ecclesiastical architecture) in a structural complex known as Zacuala, which we reproduce in Figure 20. In the central cartouche of this mural there is a' radiant mouth', and from this cartouche four unmistakable greenish mushrooms emerge. Beyond the mushrooms on either side are three 'disembodied eyes'. Could there be more eloquent expression in paint of the Word, of Sacred Song, under the potent influence of the divine mushrooms? How could any single picture tell us more clearly what Teotihuacán was all about? Our painting was a reconstruction by Abel Mendoza based on the surviving fragments, which amply justified his restoration.

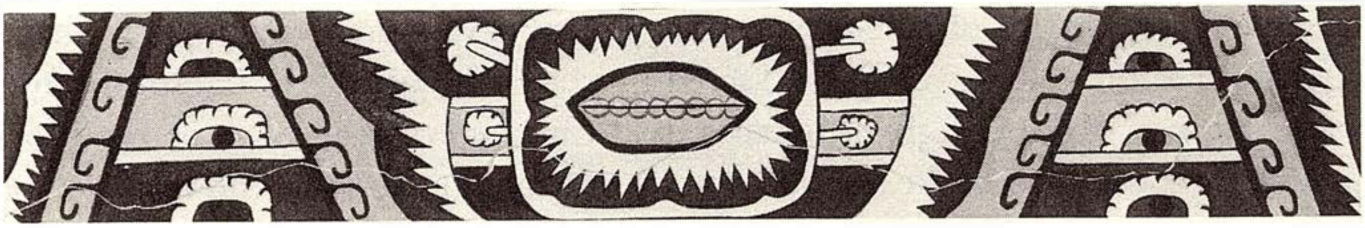

Fig 20 Zacuala: 'Predella'

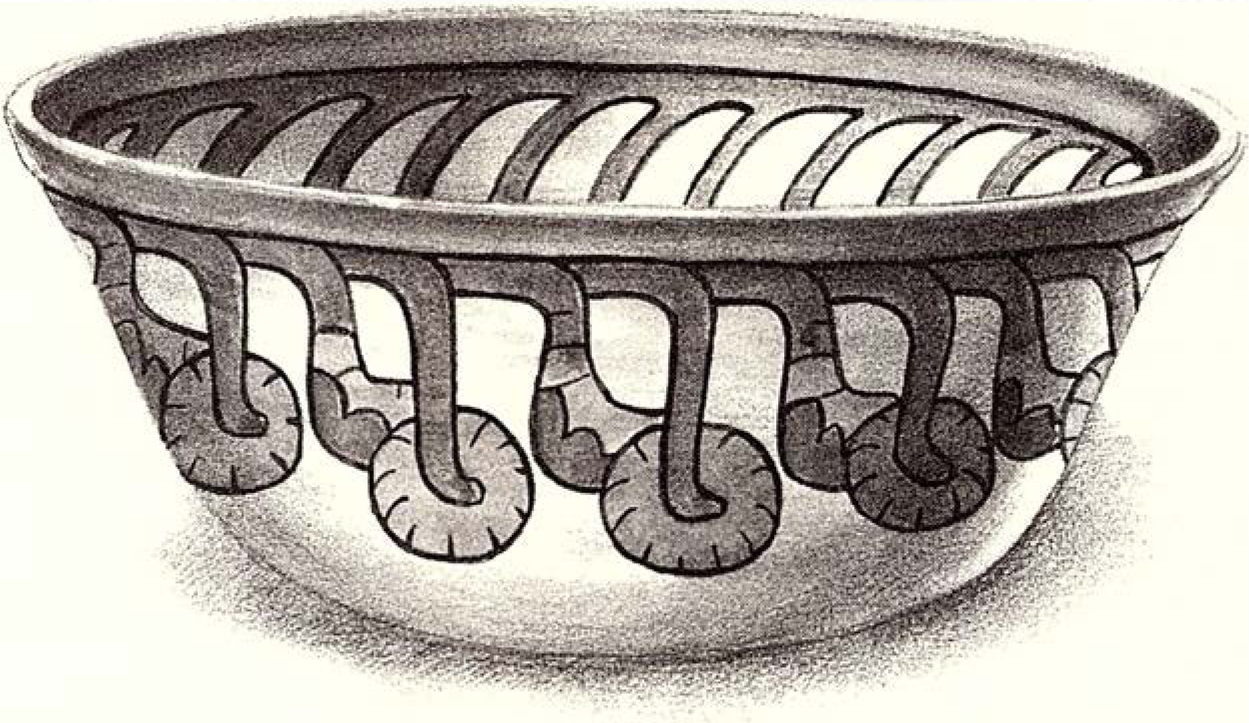

Fig 21 Zacuala: Painting of reconstructed bowl

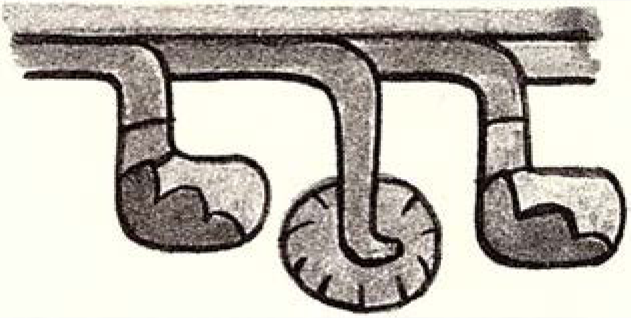

Some sherds found in the débris of Zacuala permitted Mendoza to paint a terra cotta bowl decorated with a row of mushrooms encircling it and a second row, behind the mushrooms, of seashells. (Figure 21) I like to think this was a utility vessel to carry the mushrooms to the cenaculum where they were needed.

Chalchihuitl and Tonallo: a speculation

Small rings of jade played a prominent part in pre-Conquest Mesoamerican culture. Scholars seem to think this was because of the high value placed on the jade. Green, the color of jade, was always a symbol of enhancement, as we have often seen in the color given to the sacred mushrooms. But surely the mushroom comes first. It is colored green because its divinity merits the color of the most precious stone known to the Mesoamericans, though for the awesome mushrooms it was contrary to nature. The jde rings are precious, of course, because they are of jade but basically because they exemplified the sacred mushrooms. Agustín Villagra in his chapter on the 'Mural Painting of Teotihuacán' in the *Handbook of Middle American Indians* (1971, Vol 10, p 141) shows us the surviving elements in the facade that is peopled with *chalchihuites*, jade-green rings, which he has kindly reproduced for us. (Fig 22) He is right: they are the representations of jade-green rings. But surely they represent something infinitely more precious, the divine mushrooms. There is an intimate reciprocity between the jade rings, shaped to represent the glyph for mushroom and carved from the most precious stone, and the mushroom painted green like jade, the acme of holiness. A chalice designed by the finest goldsmith and jeweler, a Cellini-conceived cup, merely aspires to be worthy of the blood of Christ that it is destined to hold. The green *chalchihuites* to which Villagra calls our attention in the Road of the Dead are only a symbol of the jade rings that in turn speak for the wondrous mushrooms.

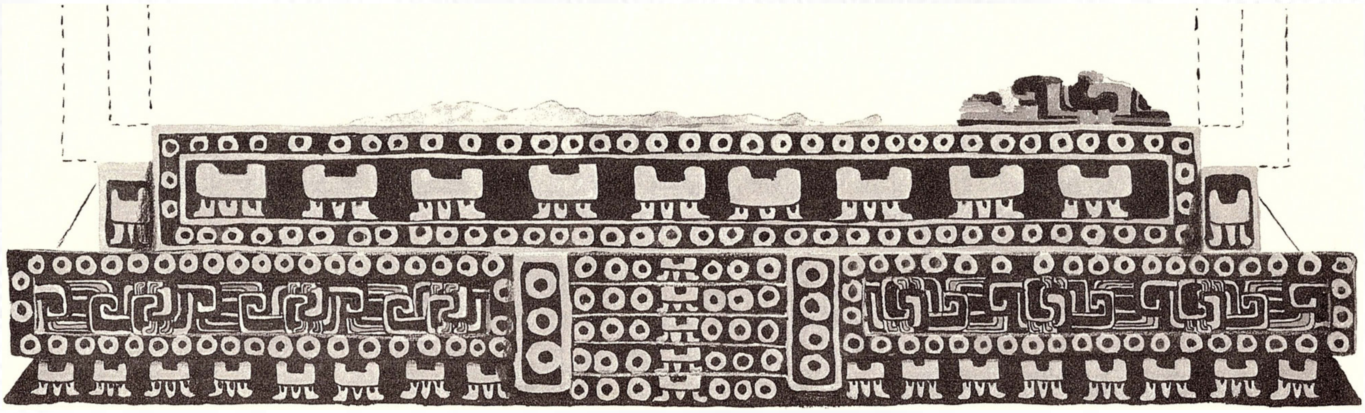

Fig 22 Teotihuacan: surviving elements of facade in the Road of the Dead, painted by Villagra Caleti

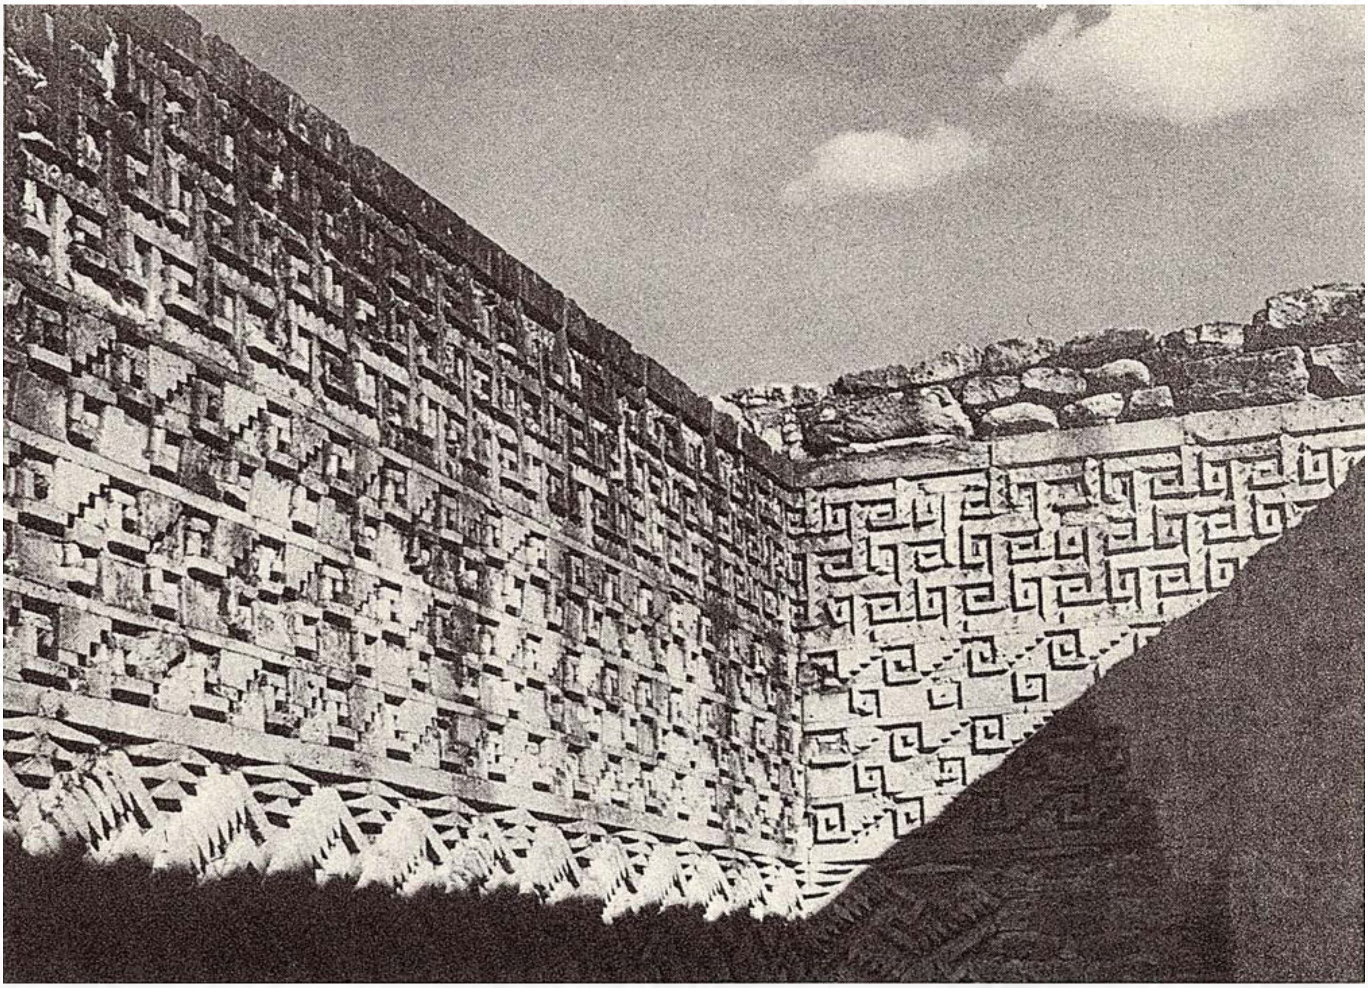
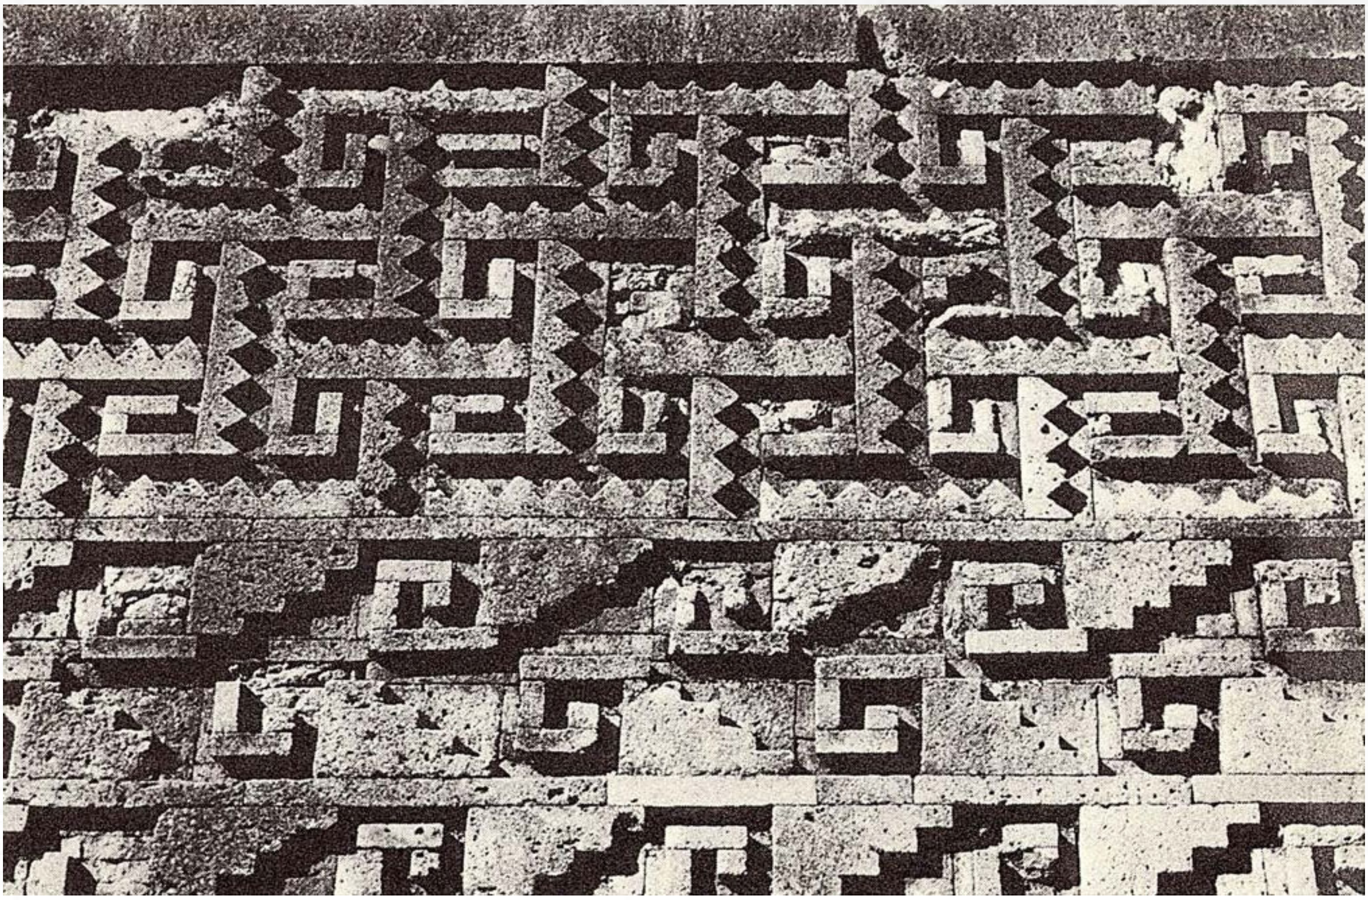
Again let us take the *tonallo* symbol. (p 64) What is the derivation of that symbol? What is it ultimately but four mushrooms, the sacred number four? And what of the series of concentric rings that we have seen encircling the *tablero* of our statue of Xochipilli? (p 64) Why are they not the glyph for mushrooms rather than solar symbols? The mushrooms signify of course all the other beneficent manifestations of a favorable Nature - solar warmth, gentle rains and life-giving showers, butterflies, hummingbirds, flowers waving in the breeze, music, laughter, singing and dancing, poetry. However alien it be for us of an alien culture, the sacred *flowers* breathed life, breathed reverence and joy, into all these other pleasant aspects of existence on this earth.

The superior entheogens of Mesoamerica - primarily the mushrooms and morning-glory seeds - all interrelated chemically, at the outset of the visions that they bring, more often than not start with abstract designs, for me mostly angular but for others often sinuous, curving, serpentine. They are breathtaking in their clarity, three-dimensional, in color, constantly shifting, changing, as it were dancing. We have already pointed out that these motifs recur in the finest of the Mesoamerican codices. I think this explains their haunting beauty that many have felt when contemplating them. We have suggested that this was why the codices were venerated beyond any reason that the Spaniards' mentality could grasp: the characters were inspired by the divinity that dwelt in the entheogen.

The architects of pre-Conquest Mexico let themselves go in complicated 'frets', borders usually with angular designs endlessly repeated, or else in rhythmically curving lines, and in Figures 23 and 24 we show photographs of these 'frets' from the ruins of Mitla. The same theme can be seen in Teotihuacán but the Mitla 'frets' serve to show how widely scattered they are in Mesoamerica. The 'frets' in Spanish are called *grecas* as they are also in Italian. *Greca* simply means 'Greek'. Is this not odd? Why 'Greek'? The *grecas* of Mitla could not have been inspired by Greece, nor did the Greeks learn to design their *grecas* from Mexico. Both, I suggest, were inspired by their respective entheogens, in Mesoamerica by the entheogens that by now we know well, in Greece by the sacred potion drunk at Eleusis and certainly elsewhere, coming from entheogenic mushrooms called Claviceps parasitic on barley or other grasses. There have been arguments about the swastika, which occurs in remote parts of the world to all appearances autochthonously. Or is diffusion the explanation? The answer surely lies rather in the natural diffusion of the plants producing entheogens instead of the diffusion of art motifs. To illustrate this we show in Figure 25 an amphora of the archaic period (ca BC 640) from Eleusis. Interspersed among the figures there are many ornamental 'fillers', as the art historian is apt to call them, which are simply our '*grecas*' broken down into isolated art motifs. The Greek art historian has generally said that this vase gives no clue to what took place once a year in the sacred precincts of the Temple to Demeter. But as he was not present on that night of revelations he of course does not know, and now that we are familiar once again with the abstract designs engendered by the entheogens, this new evidence tells us with certainty that the artist was drawing his inspiration from the potion of Eleusis. Such designs were the common property of initiates everywhere in the Age of Entheogens. Marija Gimbutas has revealed to us a wealth of such designs from artifacts running back to the fourth and fifth millennia B C, mostly from what she properly calls 'Old Europe' but what we know today as the Balkans. (The inhabitants of Old Europe, whoever they were, possessed cultivated barley and wheat and therefore ergot was available to them, in addition to several other entheogenic mushrooms.) She also reproduces the design (Fig 26) of a gold ring recovered near Knossos, ca BC 1500, showing a vision of five whirling females (Maenads?) with insect heads and 'hands', and a 'disembodied eye', which I suggest is the eye of the hallucinating observer.



Figs 23 and 24 Mitla: *grecas* in ruins of the pre-Conquest temple



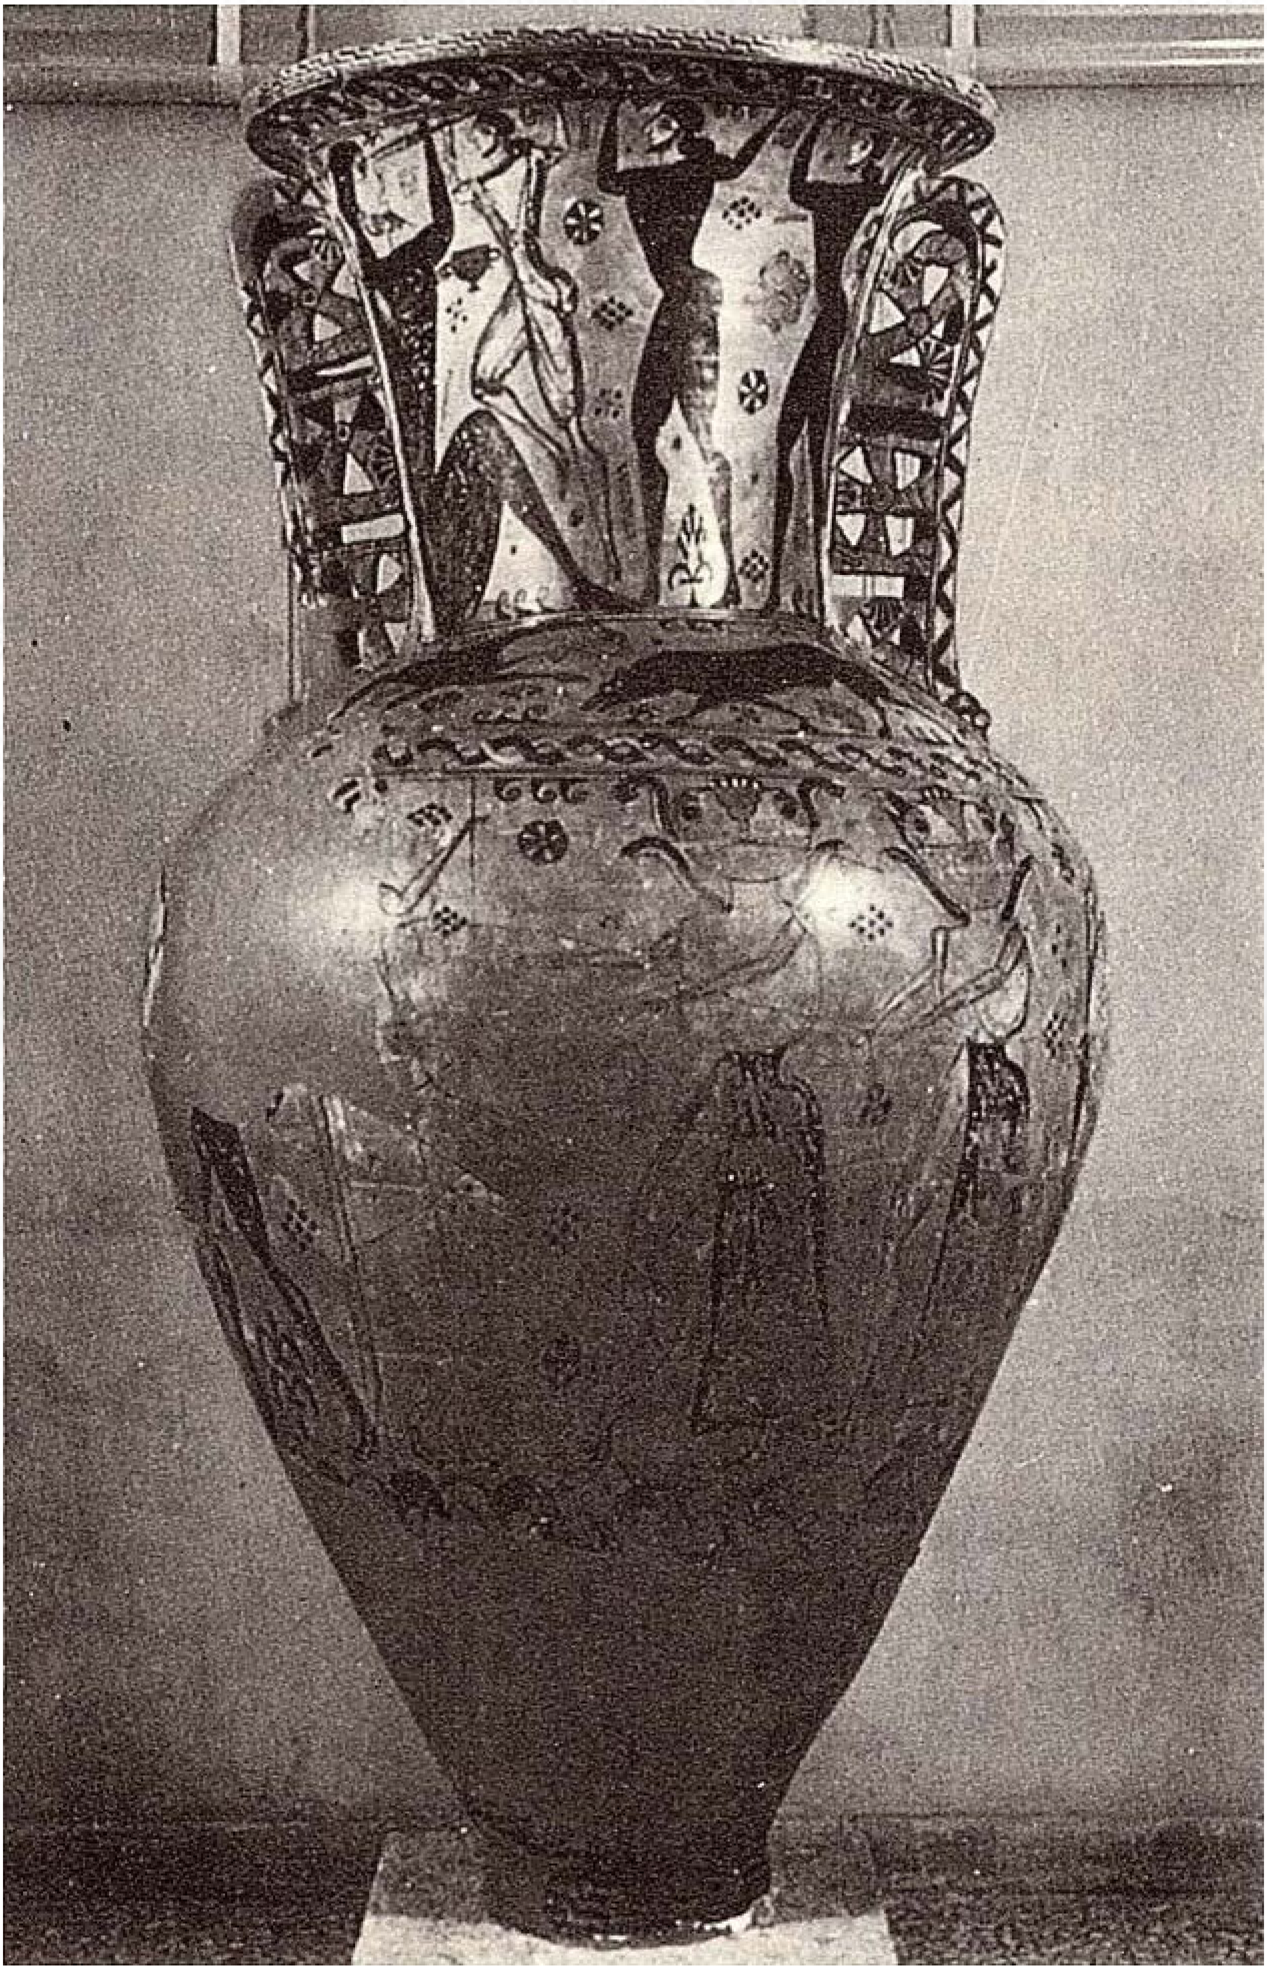


Fig 25 Archaic Greek amphora found in Eleusis

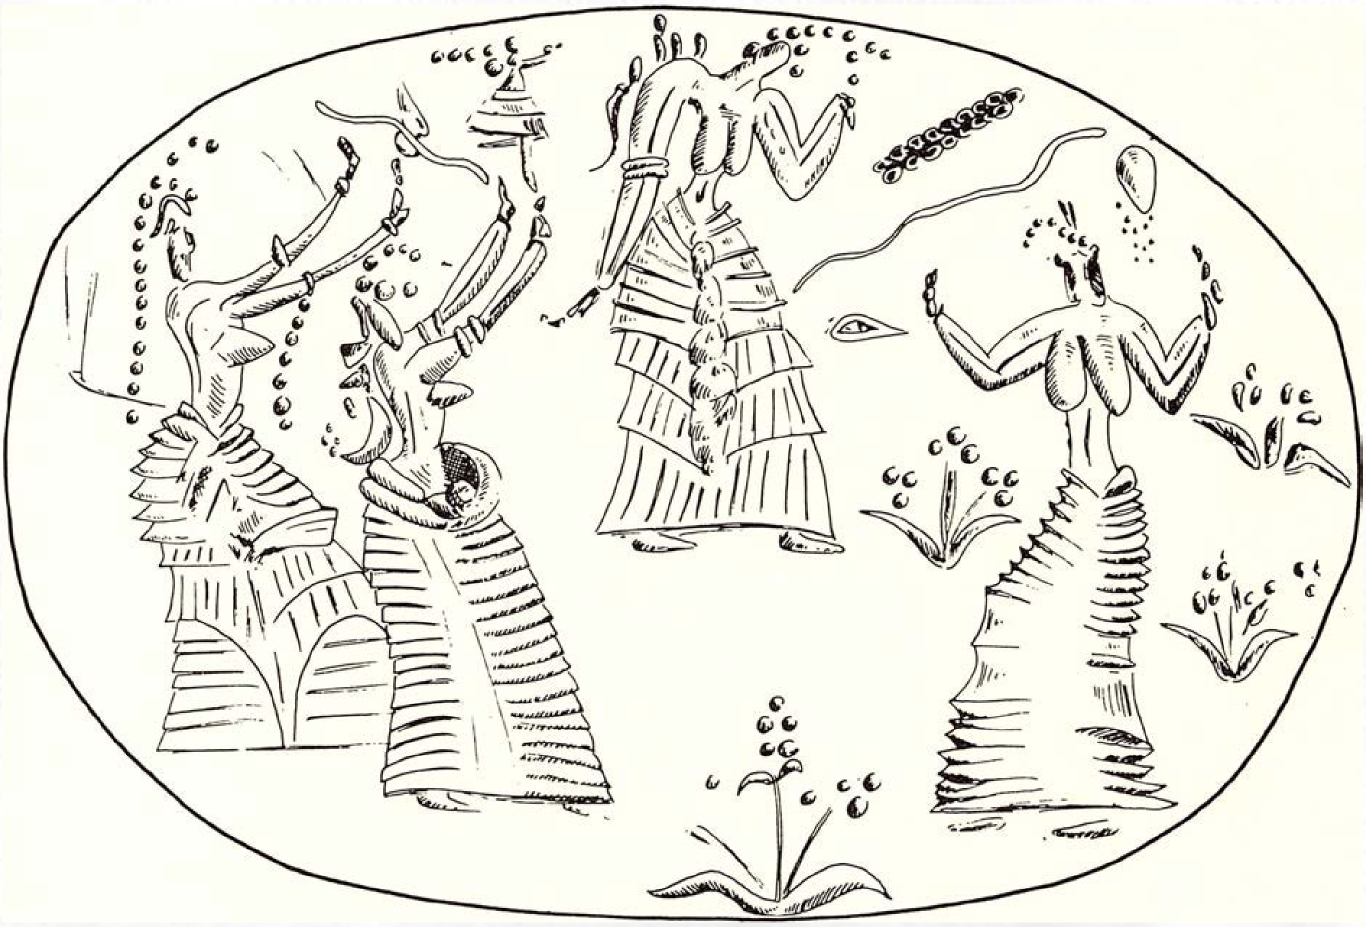

Fig 26 Gold Ring of Isopata near Knossos. Goddess on right and worshippers. Note disembodied eye. Much enlarged.

Teotihuacán belongs to prehistory. We cannot even be sure what language was spoken by the natives of that vast city-sanctuary. But its dimensions are so great that I suggest it was the religious capital of all Mesoamerica, and that for many centuries. Here is the explanation of the cultural amalgam that united so many peoples of diverse linguistic families, of diverse origins, living in widely different climates and ecosystems: that explanation lay in the entheogens and specifically in the Wondrous Mushrooms. For the native they were miraculous. Miller in his book on Teotihuacán even points out the plunging god that I think was Piltzintli, an aspect or manifestation of Xochipilli. The *veladas* that were sung in those chambers have their direct descendants in *veladas* being sung over wide areas of Mexico today, of which we possess full recordings in the chants of María Sabina. In 1960 I wrote:

> What you are seeing and what you are hearing appear as one: the music assumes harmonious shapes, giving visual form to its harmonies, and what you are seeing takes on the modalities of music - the music of the spheres. 'Where has there been greater rivalry between seeing and hearing?' How apposite to the Mexican experience was the ancient Greek's rhetorical question!

It is indeed surprising to discover in Mexico a common denominator with ancient Greece - in the *veladas* that were there sung the key to the Mysteries of Eleusis, in the 'ornamental fillers' that decorate the vase from archaic Attica and the frets of Mitla! There were two mushroom potions, in Greece derived from a Claviceps, in Mexico from a *Psilocybe*. The effect was the same and it was prodigious.

CHAPTER 9

The Mushroom Stones Of The Maya Highlands

Many now know about the mushroom stones of the Guatemalan highlands. They first emerged into the world's consciousness on 29 May 1898, when the famous German geographer Carl Sapper published a picture of one in *Globus*. (Figure 1) They had been discussed for some years in Guatemala in circles interested in the archæology of that country, and now finally they were breaking into print in journals of the outside world. Sapper pointed out that the mushroom stones were 'mushroom-shaped' but, strangely, failed to consider whether the sculptors might be carving mushrooms. He saw that these stones were religious. He dismissed a suggestion that they were phallic but in the end he left their purpose in the air. He was right in dismissing the erotic notion: the fungal world is filled with erotic symbolism, male and female, but when an artist sets out to present a phallus, he starts with a phallus in mind, not a mushroom, and the figurines are all mushroomic, not phallic. Sapper ends by urging that specialists in neighboring cultures be consulted to see whether they might shed light on these 'unique' figurines. But his appeal went unanswered until the Wassons linked the mushroom stones with the mushroom cult in Mexico in the early 1950's.

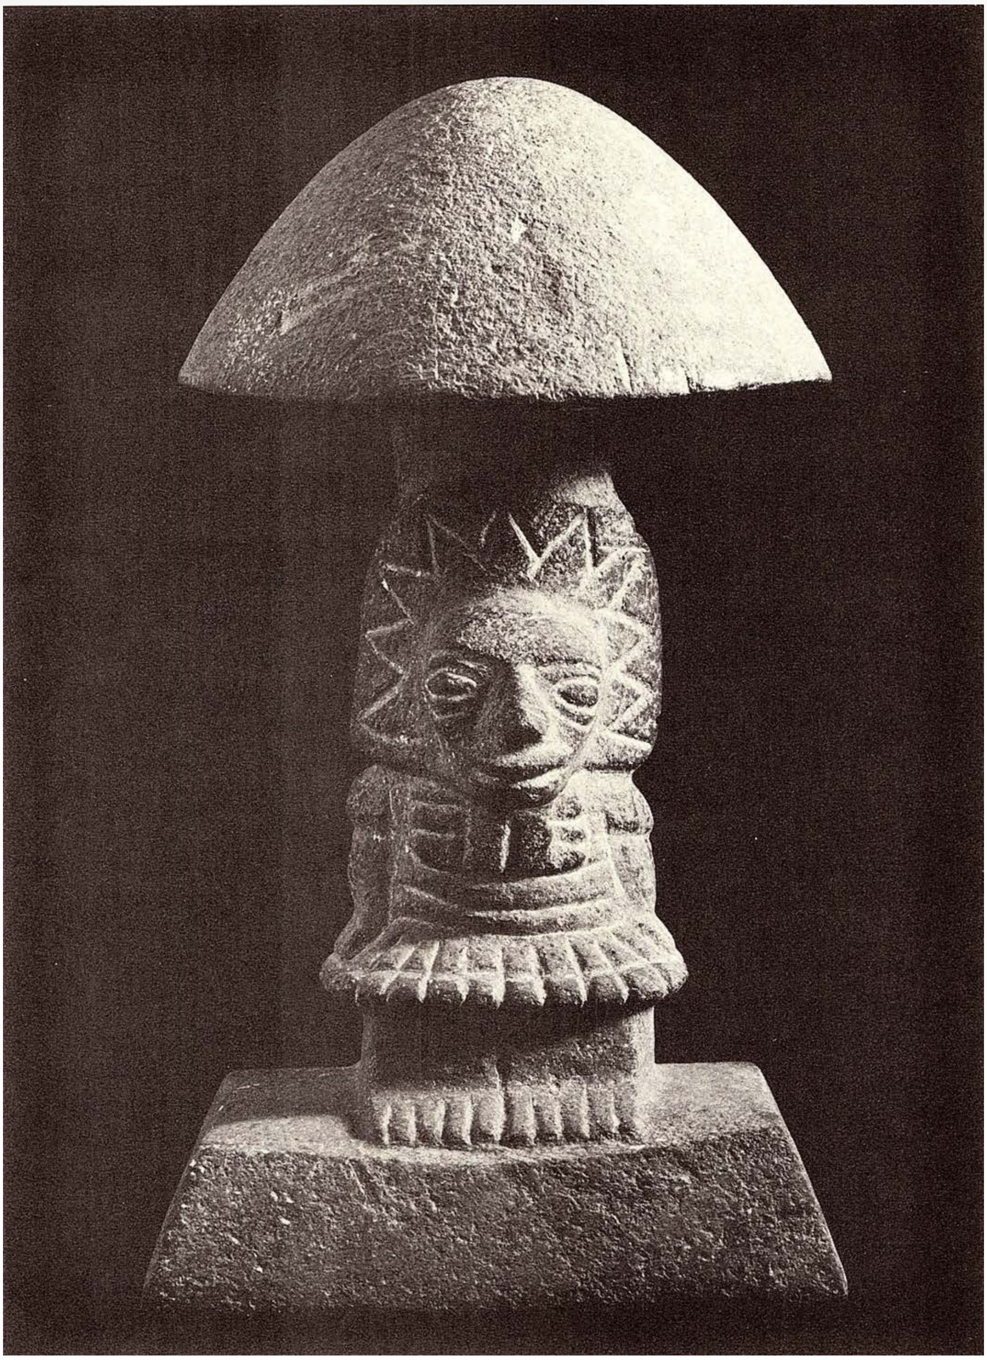

Fig 1 Earliest mushroom stone published. Now in Rietberg Museum, Zurich. Ht 32.5 cm

Two months after Sapper, on 29 July 1898, Daniel Brinton reverted to the mushroom stones in *Science*:

> I would offer a suggestion. They resemble in shape mushrooms or toadstools, and why should not that be their intention?
> [n. s., vol 8, no 187, p 127]

He then advanced a linguistic justification, discovering (as he thought) that the sounds in one of the Mayan languages for the words 'mushroom' and 'moon' were almost the same. Mayan scholars dismissed his idea, but let it be now noted that he was the first to tie mushroom stones with mushrooms. In this he was right but wrong in his follow-through. He had clearly never heard of the mushroom cult in Mesoamerica.

Archæologists in the Guatemalan highlands have been finding additional mushroom stones and many others have slid into the market from surreptitious sources, until today some three hundred are known to exist. They are in private collections and museums throughout the world. I have made a selection from the finest of them to illustrate this chapter.

When Valentina Pavlovna and I came on the Mesoamerican scene in 1952, we at once assumed that the mushroom cult reported by the friars in Mexico found full expression in the mushroom stones of the highland Maya. We propounded this thesis in *Mushrooms Russia & History* and other publications in the late 1950's, failing however to stress our surprise and puzzlement that it took us, outsiders, to see the obvious. True, we were specializing in the rôle of mushrooms in human cultures, but still we were astonished at the seeming blind spot of all scholars of European ancestry in failing to take into account what the sixteenth and seventeenth century friar-chroniclers had stressed, though inadequately. In *Mushrooms Russia & History* (pp 181-2) we drew attention to a reference to mushrooms in the pre-Conquest Mayan *Popol Vuh* in a religious context, and likewise to one in the *Annals of the Cakchiquels*, also Mayan, also religious. There are no other references to mushrooms in these pre-Conquest sources.

The late Stephan F. Borhegyi thought he discerned a tie linking the mushroom stones and the Mesoamerican ball game, for reasons that I will not enter into here. The ball game was a religious event alike in Guatemala and Mexico. (This may seem odd to some, but one need only attend a *sumo* match in Japan to see a survival of such a feeling in the ritual of those wrestling matches; and in ancient Greece the Olympic games breathed religion.) There is nothing incompatible between the mushroom stones and the ball game. Those who have mastered the mushrooms arrive at an extraordinary command of their faculties and muscular movements: their sense of timing is heightened. I have already suggested that the players had ingested the mushrooms before they entered upon the game. If the mushroom stones were related to the ball game, it remains to be discovered what rôle they played.

★

We were constantly on the lookout for evidence of the tie between the mushroom stones and mushrooms. The difficulty was that the last carvings, extremely crude, were made some centuries before the Conquest and it looked as though the stones were being abandoned at that time. We hardly dared hope to find a continuity with post-Conquest Mesoamerica.

Early in our pursuit we became acquainted with a mushroom stone in New York owned by Mr and Mrs Hans Namuth. He is a photographer and she had been born an Herrera of Guatemala. A striking piece, it came to be known as the Namuth artifact, and Mr Namuth graciously photographed it for us. (Figure 3) An elderly woman (as we thought her then) was bending over an inclined plane in front of her. The figurine was admirable but it meant nothing more to us than that.

Late in June 1960 Robert Ravicz and I made a field trip to the Mixteca together and in Juxtlahuaca we put up in the home of Robert's friends, Guadalupe González Vega and his family. On the night of 5-6 July we attended a *velada*, the aunt of our host serving us as *sabia*. The notable feature of this *velada* was the preparation of the entheogenic mushrooms: Juventina, the youngest daughter of the family, a child, a maiden (*doncella*), ground them on a *metate* over which she leaned. She ground them, as is customary, with a *mano*, a hand roller also made of stone. It was at once clear to me that the *doncella* was performing the religious office of the female figure in the Namuth artifact. There could be no doubt about it. The composition of the figurine was as close as the medium would permit the sculptor to go. (Figure 4)

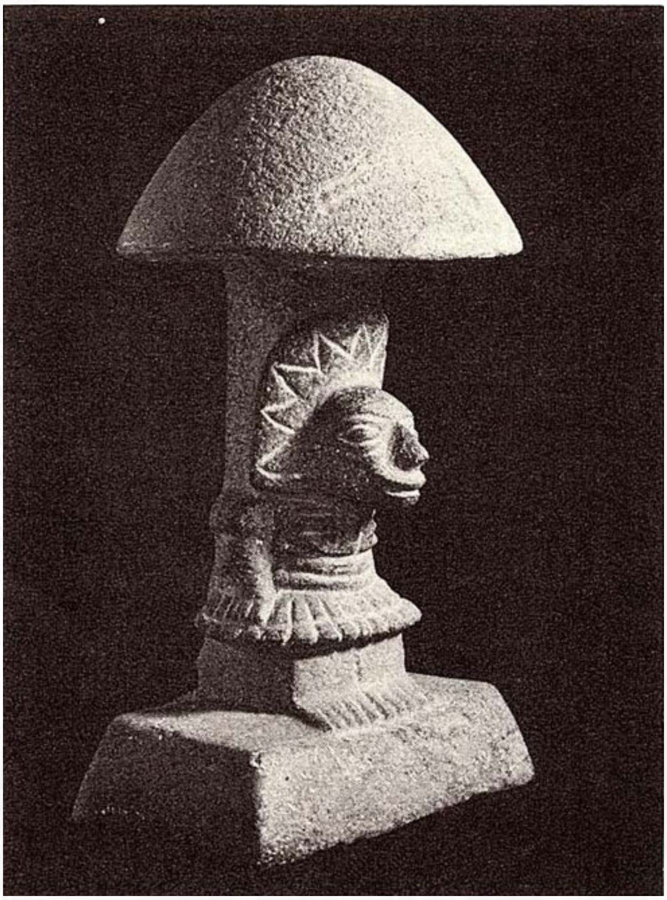

Fig 2 Second view of Rietberg mushroom stone

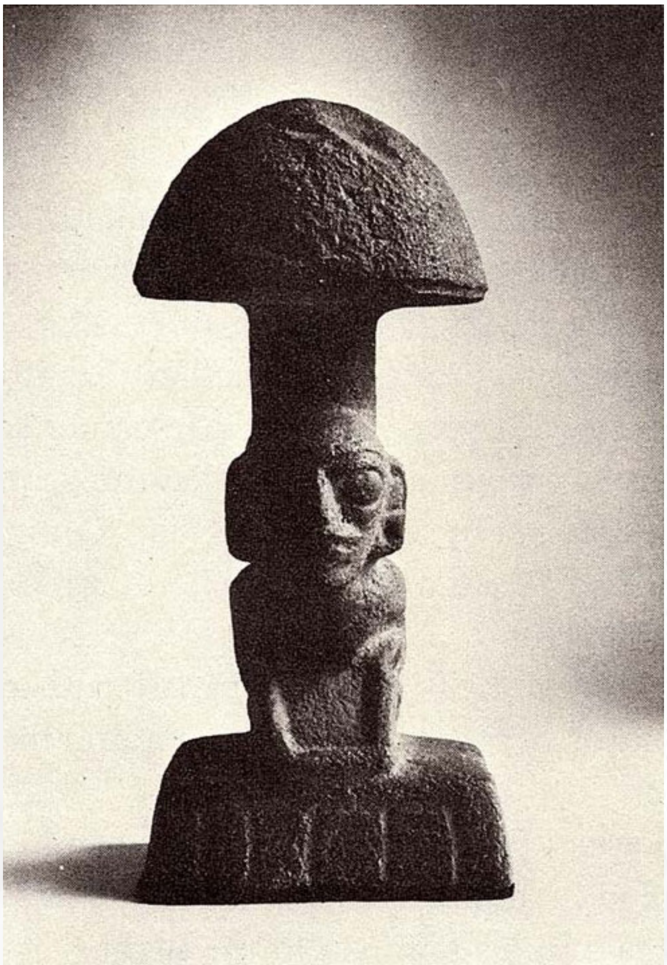

Fig 3 Hans Namuth artifact. Early photograph taken in middle 50's

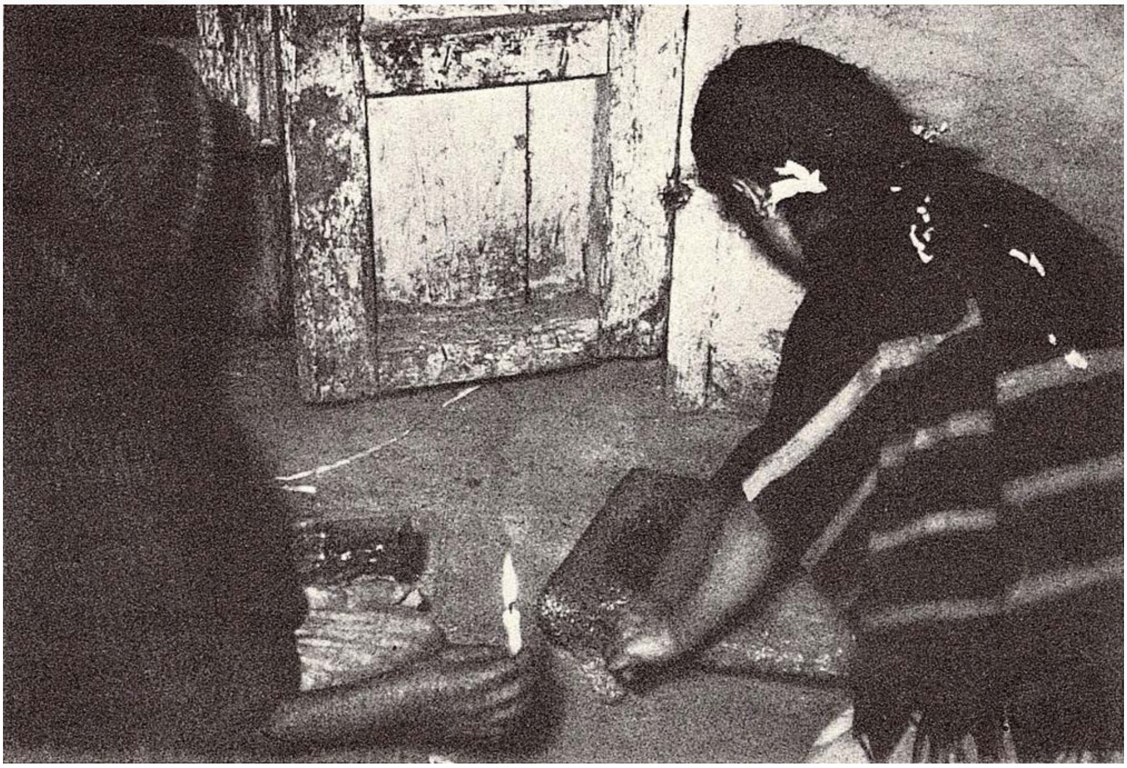

Fig 4 Young girl grinding sacred mushrooms in Juxtlahuaca, Oax., in the Mixteca

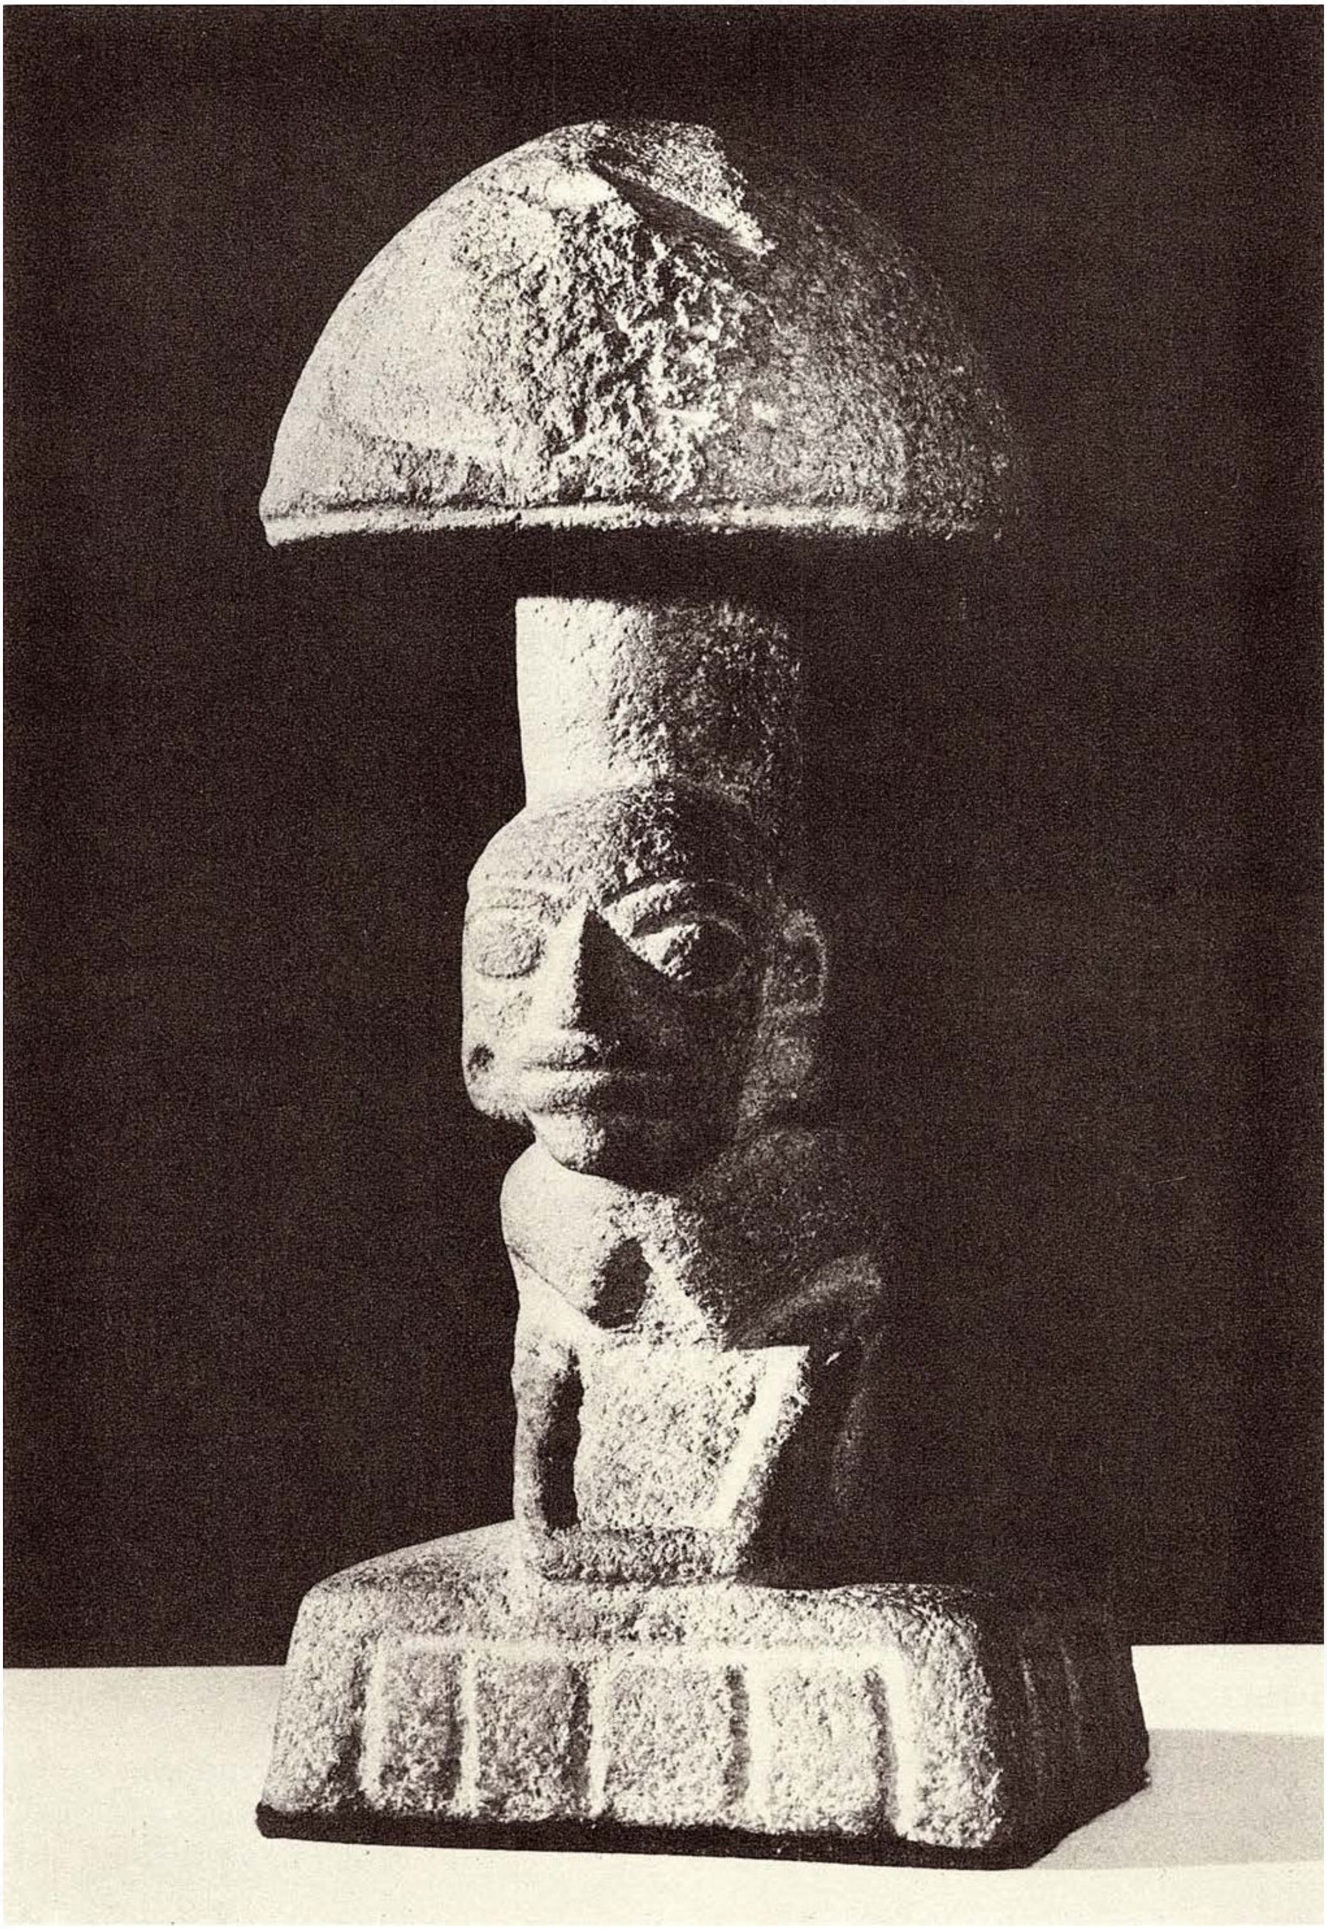

Fig 5 Second photo taken of Hans Namurh artifact in 1962

I returned to New York and on Steve Borhegyi's next visit we rushed around to the Namuth studio together: we perceived for the first time that the figure displayed the budding breasts of a virgin. We ordered new photographs that would highlight this feature. (Figure 5) In his letter dated 14 June 1962 to Mr Namuth, Borhegyi explained why we needed them:

> I am now completely positive that the figure on this mushroom stone represents a young female working on the metate.
> [Carbon copy in my Borhegyi file]

Later we learned that grinding the mushrooms on the *metate* and drinking the pulpy crushed mushrooms in water was far more widespread than we had known at the time: before the Conquest it may have been the general practice. I have given the evidence for this on pp 31-32.

Juventina in Juxtlahuaca was, all unknowing, the key to the highland Mayan *doncella* some 2000 years before.

A little later, reinforcing our Mixtec evidence, there emerged into the market place from the archæological site of Kaminaljuyu a remarkable find: nine miniature mushroom stones with nine miniature *metates* and *manos*. (Figure 6) The miniature mushroom stones were linked by physical association with the *metates* and *manos*. They supported the testimony of the Namuth artifact and of Juventina.

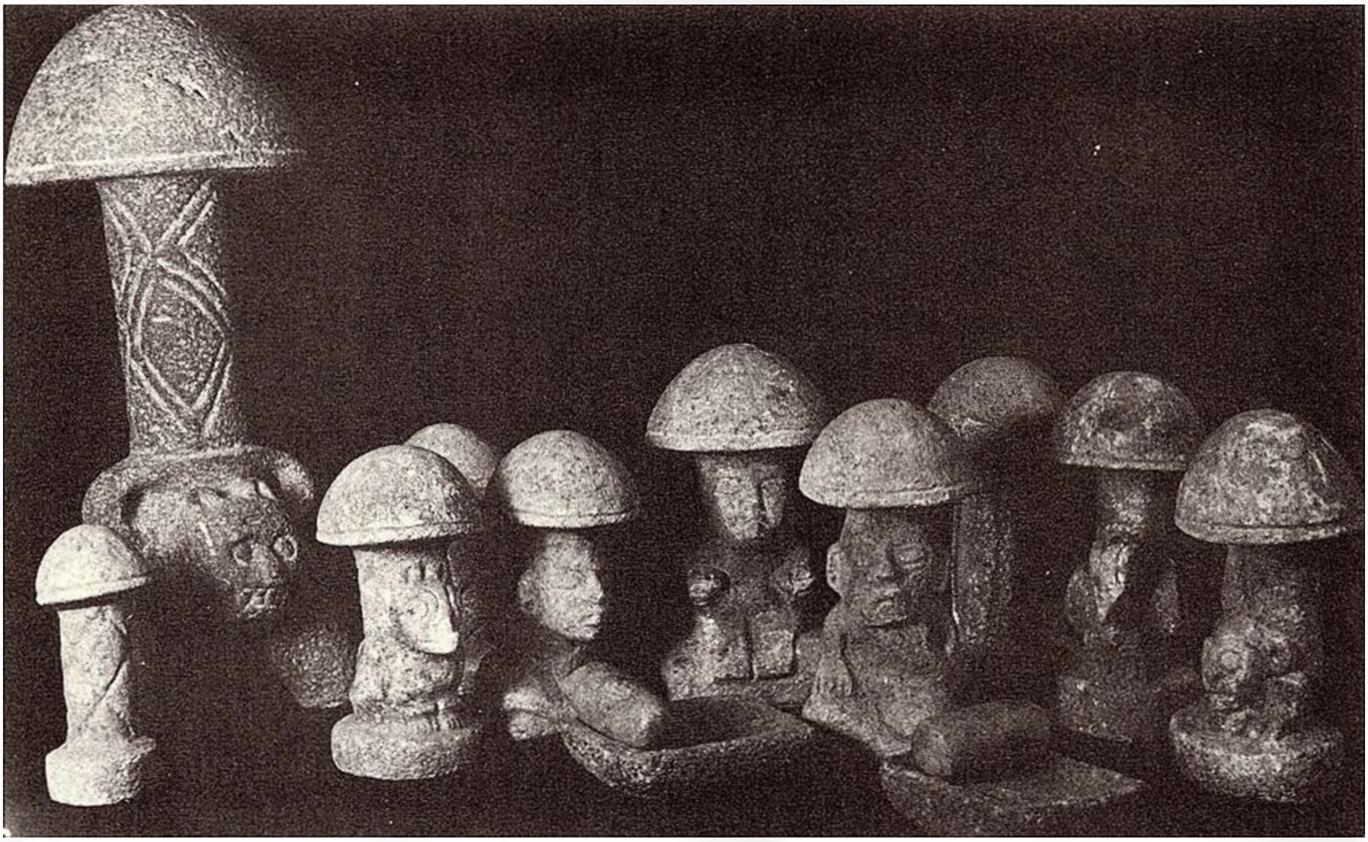

Fig 6 Miniature mushroom stones and metates, now in the Nottebohm Collection, pictured with a mushroom stone of normal size

For three weeks in 1953 Steve Borhegyi, his wife Susie, and we scoured the Guatemalan highlands seeking a contemporary use of entheogenic mushrooms. We did our best and we found none. The practice seems to have died out, but there is always a question: the Maya are more reserved than the Mexican Indians and we were less experienced then than later. We have always hoped for a breakthrough. There have been reports of the use of the sacred mushrooms among the Maya on both sides of the Guatemalan-Mexican border but the reports are not so far substantiated. Now the trails are muddied by the activities of trippers and hippies

Inexperienced observers have often remarked that no entheogenic mushrooms have been reported from Guatemala. They should realize that in Mexico Professor Heim and we had won the confidence of the Indians who brought the mushrooms to us and us to the mushrooms. To embark on a mycological survey of the highlands is an altogether different matter, much more arduous and prolonged. No reason exists to think the entheogenic species fail to grow there in abundance. Geologically the Guatemalan highlands are a continuation of the Sierra Madre in Mexico and we have always taken it for granted that the mycoflora would be the same. Bernard Lowy, Professor of Mycology at the State University of Louisiana in Baton Rouge, has been devoting a few weeks in each year to such a survey and he has lately found *Ps. mexicana* Heim in the heart of the Pokoman country. Pokoman is one of the Mayan-languages. (Fig 7) Professor Lowy is the first mycologist on record to make field trips in Guatemala.

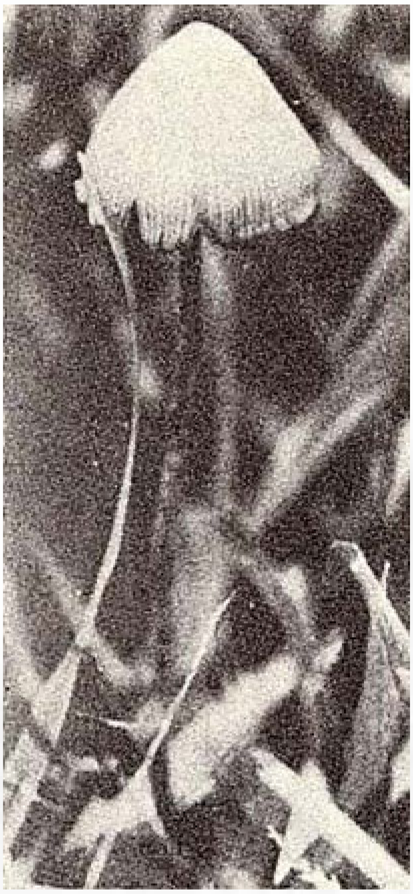

Fig 7

★

That the highland Maya knew the inebriating mushrooms is proven by a number of M ayan word lists for the Cakchiquel linguistic area around Guatemala City and Antigua. The lists that I have seen are mostly handwritten and experts date them from the end of the seventeenth century, though they bear no date. In the Tozzer Library at Harvard I discovered a photographed copy of a *Vocabulario Castellano-Cakchiquel* in which there are a number of entries for mushrooms. One reads: *hongo que emborracha*, 'mushroom that inebriates'. This word list was compiled, according to the library listing, by 'Calepino Franciscano',[31] and there is an almost identical copy in the Bibliothèque Nationale, Man. Americana, No 41, folio 106, linked with no name and written by a different and I think l ater hand. I am indebted to Karl-Herbert Mayer for discovering the Paris copy: he is assembling a notable collection of Mayan lexicons wherein the mushrooms figure. Then there is the *Vocabulario* compiled by the Franciscan friar Thomas Coto, to which Peter Furst drew my attention. It also lists *otros* [*hongos*] *que embriagan*, 'others that inebriate'. The Maya highlands and the highlands of what is now Mexico are essential areas of Mesoamerica, where there was an active give-and-take in warfare and trade throughout history and prehistory. Here is for me conclusive evidence that the use of entheogenic mushrooms existed in the highlands of what is now Guatemala. An anthropological trait as important as the use of entheogens would inevitably characterize the whole of the cultural entity known as Mesoamerica.

---

[31] In the Renaissance 'calepino' came to mean a Latin dictionary and then any bilingual dictionary, after a Latin lexicographer of that name. Calepino Franciscano = 'Franciscan Dictionary'.

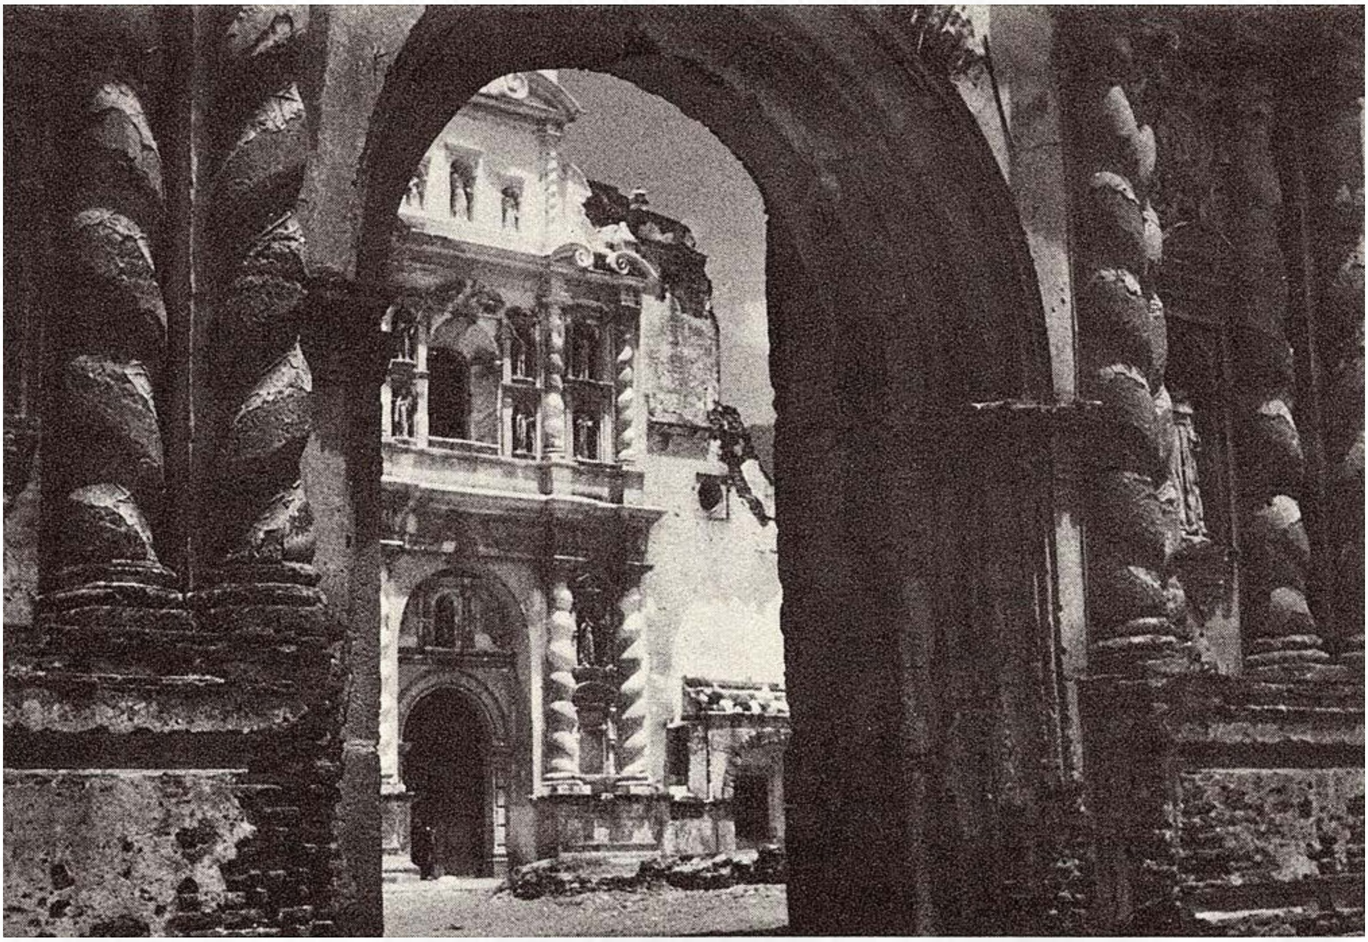

Fig 8 Church of San Francisco in Antigua seen through portal

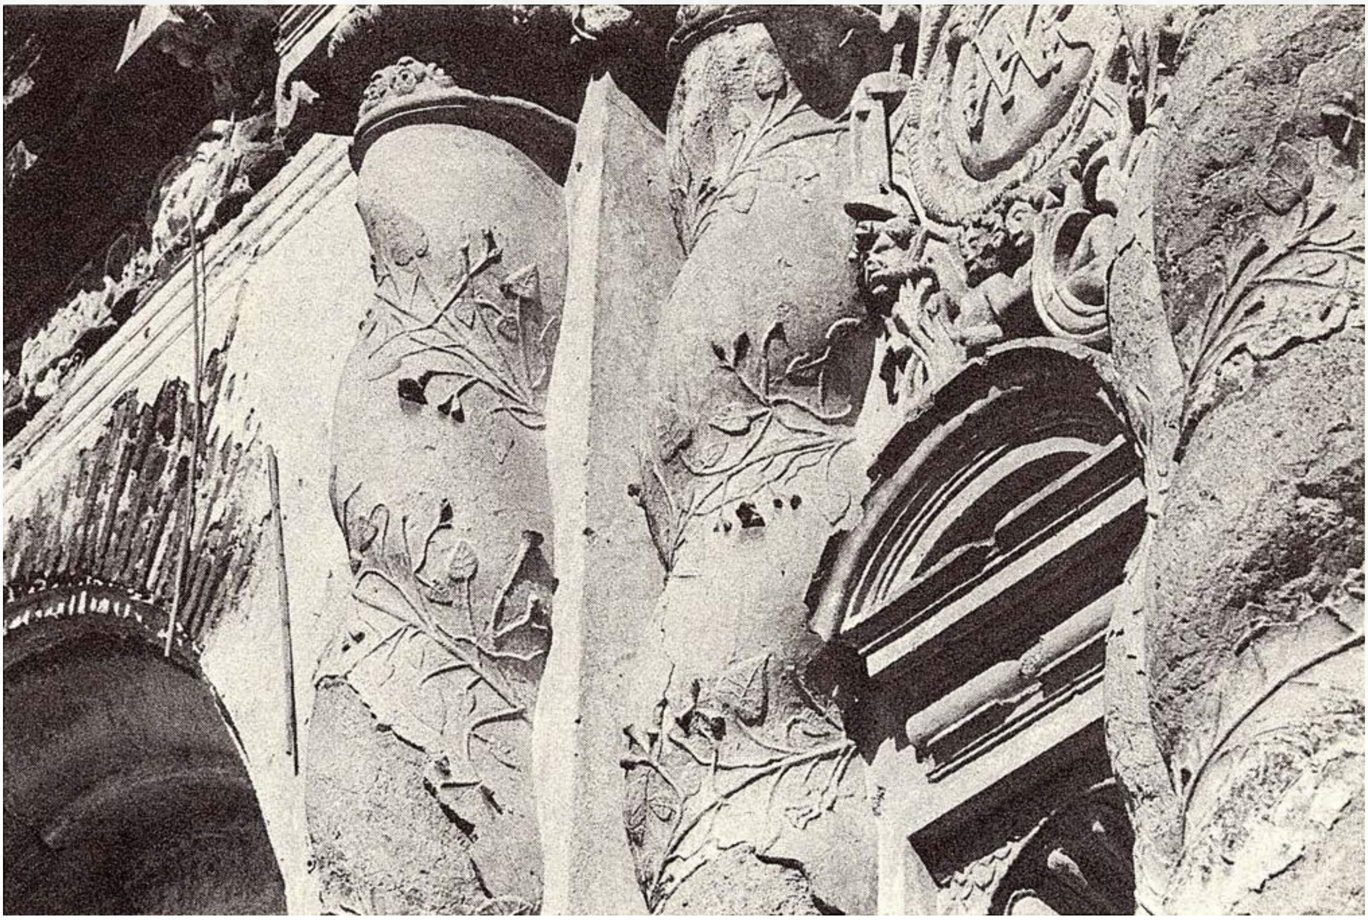

Fig 9 Detail of morning-glory carved on columns of portal

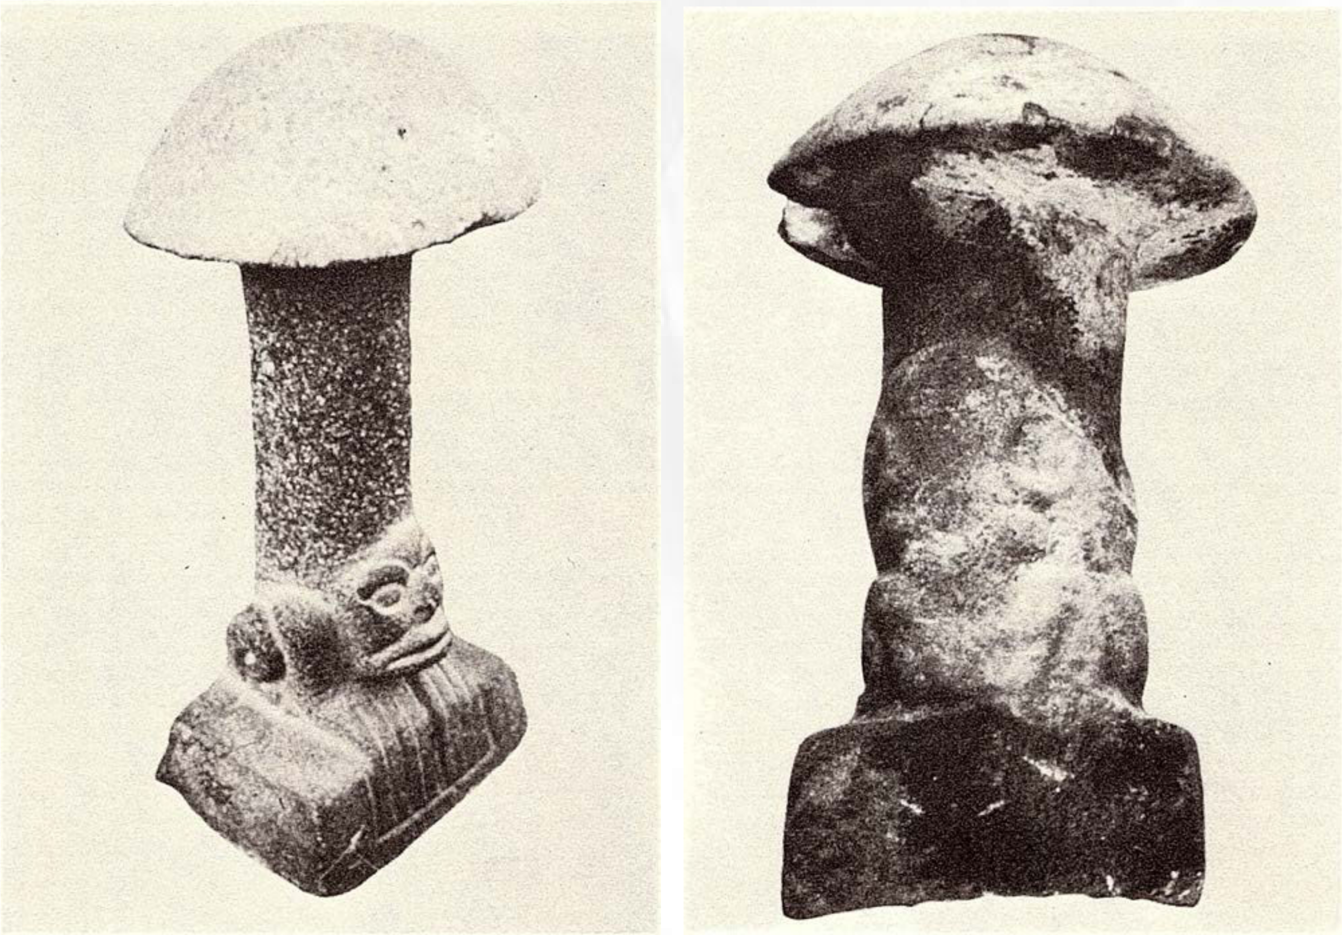
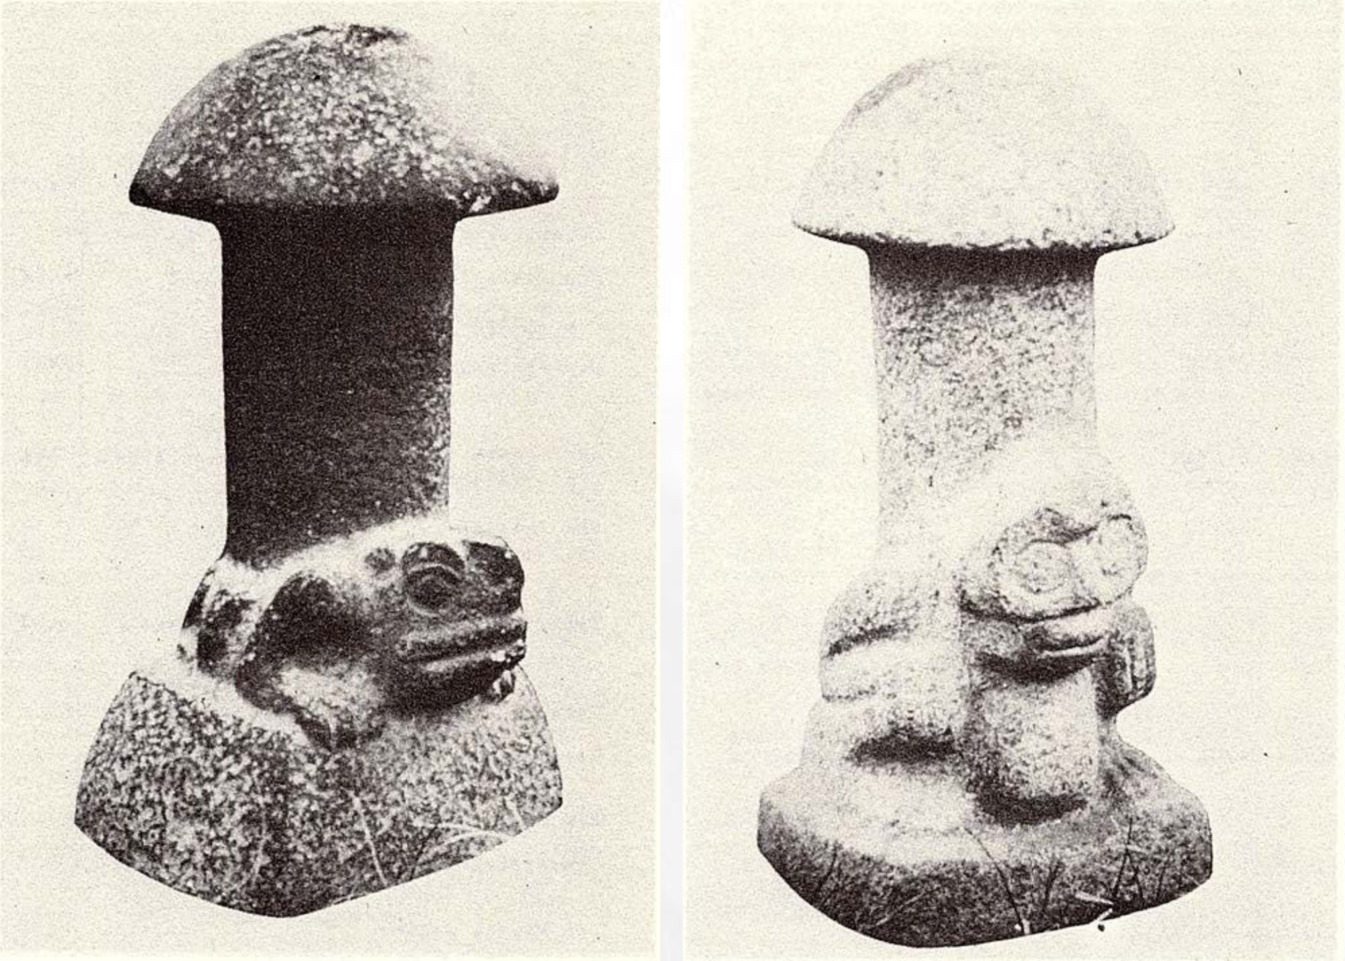
As though supporting this conclusion, Donald B. Lawrence, Professor emeritus of Botany at the University of Minnesota, has turned up ancill ary evidence in the portals to the patio of the Church of San Francisco in Antigua. This evidence is noteworthy in associating the complete pattern of entheogenic use in Mexico with such use in Guatemala. The columns of these portals were originally covered with stucco molded to represent a climber and that climber was a morning-glory. The colors are lost and only fragments remain of the climber. In Figures 8 and 9 we reproduce two views of this portal, one to place it in relation to the church, and the other, Joya Hairs' photograph of a detail. That the Indians were molding the entheogenic morning-glory seems to me evident. This was in the second half of the sixteenth or perhaps more probably in the seventeenth century. Did the Franciscan friars know what the Indians were doing? I should like to think so.

★

For readers who would pursue further the mushroom stones, I would draw their attention to Figures 10-13. In Figure 10 from the mouth of a giant toad a mushroom stone is emerging. In another, Figure 11, a mushroom rises from the back of a toad with an anthropomorphic face. In front the toad is indicated by the four toes on each of the front feet and the characteristic squat is seen from the side. We show two more mushrooms with the toad theme reiterated, Figs 12 and 13.



Figs 10 and 11 Two mushroom 'toadstools'



Figs 12 and 13 Two additional mushroom 'toadstools'

Strangely moving is the sporadic recurrence throughout the northern hemisphere of this chthonic deity, the toad, with the entheogenic mushroom. It survives to this day in the Basque language (*amoroto*, 'toad mushroom', *A. muscaria*), in rural France (*crapaudin*, *A. muscaria*), in Chinese (*hama chün*, 'toad mushroom', *A. muscaria*). In Old French le bot was a toad, the Devil, and a mushroom. (By 'mushroom' did the lexicographer mean any mushroom or a specific kind that he did not identify? A *crapaudin* perhaps?) The same association survives in far wider circles in those mycophobic lands where through taboo the handsomest of all our mushrooms has lost its name and what had been its name is become the designation ('toadstool') of every mushroom that the seeker distrusts, above all *A. muscaria*, which he *knows* he should distrust. How far back into the stone age must this association carry us! In Mesoamerica *A. muscaria* has been replaced by the superior Psilocybe species.

In our 1953 travels throughout the Maya highlands we discovered a convergence of three ideas in one Mayan word: 'toad', 'mushroom', and for the external genital organs of the woman. (*Mushrooms Russia & History*, p 280) Borhegyi sent us afterwards a chart in diverse Mayan languages and dialects giving us supporting evidence for this in Quiché and we reproduce that chart here. This linguistic pattern is not confined to Mayan languages. How widespread it may be, I do not know. Among the Kogi of Santa Marta, in the Sierra Nevada of Colombia, Gerardo ReichelDolmatoff writes:

> For a Kogi the toad symbolizes the feminine sexual organ in an aggressive and insatiable sense. Linguistically the words 'toad' and 'vagina' are identical (*maukuí*) and on occasions a man may refer to his wife as 'my toad'.* Mention of the word or the mere sight of a toad provokes hilarity and disgust. Young people laugh and the elderly become angry. It is a 'bad word'. The 'toad is ugly'. The toad is a woman, is the feminine sex. 'The toad eats worms', is a very common obscene phrase which being interpreted means the way that the feminine organ 'eats' the masculine.
> * In the dialect of the *Sancá* no word.exists to designate the feminine organ and a hybrid is used: *sapi* or the euphemism *soma* = 'flower'.
> [*Los Kogi*, vol 1, p 268; 1950, Bogotá. Translation mine: RGW]

* pudenda muliebris

** KOXOÍ = pudenda muliebris

Fig 14 Chart of diverse Mayan languages and dialects, showing popular identification in Quiche of toad with female genitalia

How odd is this association of ideas throughout the northern Hemisphere! Perhaps the toad in Figure 10 is swallowing the mushroom, not giving it birth. We see our Mesoamerican toad in Hieronymus Bosch in his *Seven Deadly Sins* in the Prado (Figure 15) and we see it also in the mosaic of the ceiling in the Baptistery of Florence. (Figure 16)

In the association of these ideas we strike a vein that must go back to the remotest times in Eurasia, to the stone age: the link between the toad, the female sex organs, and the mushroom, exemplified here in the Mayan languages and the mushroom stones of the Maya highlands. Man must have brought this association across the Bering Strait (or the land-bridge that replaced it in the ice ages) as part of his intellectual luggage.

★

When we look at the mushroom stones we must always remember that in pre-Conquest times most art, if not all, was religious, as it once was in Europe. And we must remember that the hold on the inner life of the Mesoamerican peoples of the entheogens, notably the entheogenic mushrooms, was all-powerful, as it is to this day in remote corners of highland Mexico. Those who have not explored the rôle of the entheogens in the cultural past of Mesoamerica easily overlook that rôle or assume that it was of minor importance, solely because for us it is of no importance.

To sum up our argument, then, and without suggesting the use to which the mushroom stones were put, I have shown, thanks to the Namuth artifact, that the sacred mushrooms were crushed on a *metate* by a maiden. It is certain that the entheogenic mushrooms flourished in the Maya highlands and that they and (thanks in this case to Donald Lawrence's keen eye) *ololiuhqui* were there used. The friars learned of the use and included the entheogenic mushrooms in their word lists of the Cakchiquel language. We have arrived at verbal associations of ideas - toad, *pudenda muliebria*, and mushroom - that link them, long long ago, with the same verbal associations in Eurasia.

There came to light in the late 1950's a terra cotta artifact representing an Indian woman, seated cross-legged on the floor, with her right hand on a plain hollow pottery mushroom and the left hand raised in air: she might be supplicating or giving voice to an oracular utterance. (Figure 24) This figurine is until now unique. The late Stephan F. Borhegyi said that it came from Tenenexpan in the State of Veracruz and it is, appropriately, in the style of a Remojadas piece, with the exposed sections of the woman's legs and arms covered with black asphalt paint (*chapopote*). The woman wears a turban-like headdress, a *quexquemitl*(a kind of shoulder cape), a beaded necklace, and a wrap-around skirt. In the middle of her back is a hole (Figure 25), which communicates with two round apertures in her upper lip under her nose, serving as nostrils, and one can blow smoke of tobacco or copal or aromatic plants through this hole in her back and out of her upper lip.

Our figurine fits well into the pattern of mycolatry that I have given in the pages of our book. It is a superb expression of the religious faith of a people who held the entheogenic mushrooms in awe, both for their ecstatic potency and their divinatory powers. It dates from the classic period, ca A D 300.

29 July 1977

I had reached this point in writing my chapter when there reached me by post a copy of the doctoral thesis on the mushroom stones submitted by Dr Richard M. Rose to the Department of Anthropology of Harvard University in June 1977. In it he advances the novel thesis that the mushroom stones served a 'utilitarian' purpose in the making of the rubber balls used in the pre-Conquest ball game in the Maya highlands. He assembles evidence of the widest diversity to support his position and I think he makes good his case. I also hope he is right for he has supplied the missing copestone to support my mushroomic interpretation of the mushroom carvings of the Maya highlands. Somewhat strangely, Dr Rose does not see this, perhaps because his concentration on his voluminous and diverse evidence, all of it pertinent, has blinded him to the larger view. He has opened the door to a fresh discussion of Maya culture and the mushroom stones. What is 'utilitarian' is often also religious: designing and shaping a superb chalice is both a 'utilitarian' and a religious act. All art in pre-Conquest Mesoamerican society, or virtually all, is inspired by religious beliefs. At that time there was no 'art for art's sake', no *genre* art. The Maya ball game was, in essence, a religious observance.

From the beginning it has been known that the ball game of Mesoamerica was played over a much larger area than Mesoamerica: throughout the Caribbean islands and northern South America. Rose has explored the sources for this ball game over the whole area including the parts of Mexico that are north of the cultural entity known as Mesoamerica. He has come up with relevant data of fascinating kinds. The ball was of course of rubber. As the Maya did not know the vulcanizing process, a new ball presumably had to be made for every game. In making the ball, strips of latex were stretched on a round and roughened surface, the cap of our volcanic-stone mushrooms, and when the strips had hardened to the proper point they were removed and molded into the rubber ball. The pottery 'mushrooms' of El Salvador and Tabasco are smooth but *the cap is skillfully roughened* by pecking to the required degree, making the cap surface comparable to the mushroom stones. Rose enlists further evidence of a surprising kind: it has long been known that 'mushroom' caps have been found, not fragments of mushroom stones, but deliberately carved caps without pedestals. Until Rose no one could explain these beautifully carved caps and little attention had been paid to them. These caps date from the early phase of mushroom stone carvings. Rose thinks they were held in the hand and served the same purpose as the mushroom stones. Here then we find a use for these caps, until now unexplained.

Thus through more than a millennium and a half the mushroom stones apparently served the purpose of making rubber balls for the ball game, the artisan sitting on the ground, his legs encircling the mushroom stone, and applying by hand the latex in strips to the round mushroom cap.

We know something of the paraphernalia that the players in the ball game wore but of the rules and practices of the game we know little. The stakes were high, in the great games the very life of a player being the forfeit. We of modern European provenience naturally assume that the captain of the losing team was decapitated. In a society where the standards were utterly different, I am not so sure. The divinity to whom the game was dedicated deserved the sacrifice of the best, not the second best. The glory of winning the game and the plaudits of the attending throngs, plus his own transcendental beliefs, might well have led the captain of the winning team to off er himself to the sacrificer with the physical courage before certain death that was the crowning glory occasionally open to the Mesoamerican and North American natives. We see a parallel in the deaths of those Christian martyrs who presented themselves of their own volition to judges who would surely send them to the stake.

Henry Munn and I, independently of each other, have pointed out the extraordinary control, the precise timing, that the mushrooms generate in the shamanic ingester. It is the neophyte who staggers, who even steps off a cliff or out of a window into space. I now ask anew whether the ball player did not take the entheogenic mushrooms (or infusion of ground morning-glory seeds) before the game started and play under their influence. For the players as for the attendance the emotional tension of the game must have been awesome, each side fighting to win and the winning side (as I believe) having the honor of surrendering their captain to certain and quick death. Naturally in our pusillanimous, self-indulgent, permissive society such standards are inconceivable.

Those of us who have spoken for a conscious mushroomic use of the mushroom stones have never known what that use was. Twenty years ago we ventured the guess that they had served a ritual purpose in such *veladas* as María Sabina has sung throughout her life. No supporting evidence for this hypothesis has been discovered. Lately I have explored the activities of the Princes and Nobles of the Nahua with the divine mushrooms and have now recorded these doings in the preceding chapters. We can be certain that when they sang their poetry, when they entered upon the dance, they did not stammer, they did not stagger like drunken men. Their words glow with the wondrous religious passion that most - not all - of us in the West have lost. But the anthropologist, though he need not share in these beliefs, fails in his duty when he does not allow fully for them in studying Early Man, whether long ago or among his survivors in our own times.

When the child Juventina crushed the sacred mushrooms on the *metate* in Juxtlahuaca, she was performing a religious act as well as a utilitarian one. When the sculptor carved the beautiful Namuth artifact, he was depicting the same performance in stone as faithfully as the limitations of his medium permitted, and his carving expressed religious belief. The nine miniature mushroom stones with the nine miniature *metates* and *manos* speak for themselves in the same way. The toad effigy mushroom stones express a tripartite association of ideas that link in a common embrace Early Man throughout the Northern hemisphere. The craftsman who carved the stone shown in Figs 17, 18 *must* have been aware that he was carving a mushroom, as well as an artifact to serve in making the rubber ball. Dr Rose sets forth fairly the evidence offered us by the Namuth artifact but then fails to discuss it and draw conclusions. He fails to see the import of the miniature mushroom stones lying in a common cache with the miniature *metates* and *manos*. He ignores the toad symbolism in the toad effigies carved on four mushroom stones. He gives only a sentence to the terra cotta figurine, a woman with her right hand on a mushroom, her left hand raised in a speaking gesture, the Remojadas artifact found in Veracruz and dating from the time of Christ or shortly thereafter. (Figs 24-25)

If the mushroom stones of Guatemala were carved primarily for the making of rubber balls for the ball game - and Rose may well be right in thinking so - this in no way diminishes the relevance of the mushroom to the stone: Early Man was accustomed to see in superficial resemblances profound meanings. Similarities in the sound of distinct words are today dismissed as fun puns or as sources of confusion in the ambiguities that they provoke. But in preliterate times paronomasia, as such verbal identities are called, led to deeper misinterpretations, mistaken folk etymologies, as in the case of 'Soma'. And this was even truer in semiotics - communication through means other than words - as is to be seen in the (for us) absurd meanings placed on the forked root of the mandrake. From earliest times the stone cutter carving his volcanic rock to serve for making rubber balls must have associated this holy stone with the holy plant that it resembled, its sacral meaning being vastly enhanced by the overlapping of the two shapes. In fact, the mushroom may well have been, in this case, a prime motive in leading to the evolution of the cap into the tripartite mushroom stone.

Rose concedes, though grudgingly, that the hallucinogenic mushrooms were used in the Maya highlands. He fails to allow for the way the mushrooms permeated Mesoamerican life, for which the signs have been avail able to all though they have not been read. He fails to see the breathtaking beauty of his rubber ball - fashioned on a *mushroom* stone, thus redoubling the religious potency of his act. Probably the fashioning was attended by religious rites before, during, and after; and thereupon the ball was thrown into the game played by both teams with skilled fury for the highest of stakes.

CHAPTER 10
The historical record

In *Mushrooms Russia & History* (1957) Valentina Pavlovna and I gathered together and published a dozen extracts from early sources illustrating the use of inebriating mushrooms in Mesoamerica. We also cited early lexicons composed by friars for the Zapotec and Tarascan languages giving native words for these mushrooms, just as we have now done in the preceding chapter for Cakchiquel, an important highland Mayan language. In *Les Champignons hallucinogènes du Mexique* (1958) the quotations rose to above a score. Today, if I am right in my interpretations contained in this book, it is useless to count the pre-Conquest and later references to the divine mushrooms, so many are they, and more are sure to be discovered, especially in Nahuatl and Mayan texts not yet translated. The blind spot of the scholarly world for the entheogens manifests itself with peculiar force here in Mesoamerica precisely because their rôle was so important.

Chronologically the divinatory mushroom first appears in a tradition preserved for us in Fray Antonio Tello's chronicle when (according to this tradition) 'Teopiltzintli' led the Aztecs to their new 'Promised Land' back in the early centuries of our Christian era. (We have told this story in Chapter 7, p 140.) No one can say that this took place but the folk memory may well be right, for the function attributed to the divinatory mushroom was a normal one for it to perform.

Much later, one of the legendary 'founding fathers' of Tenochtitlan-Mexico was Nanacatzín, the 'mushroom' (*nanácatl*) with an affectionate and reverential suffix, *-tzín*. A number of lists of the founding fathers survive and Nanacatzín's name occurs in at least two, in Fray Juan de Torquemada's *Monarquía Indiana*, at the end of Chap 3, Book 2, and in the famous *Historia Antigua de México* published in Italian by the Jesuit Francisco Javier Clavijero in 1780-1. The list of the twenty legendary founders appears only in that first edition, as a footnote in the first volume of the Italian text at the beginning of Chapter 3.

For these two historical citations I am indebted to Gutierre Tibón of Cuernavaca, that questing scholar in the byways of Mesoamerican history. He is imbued with a sense of the poetry, the mystery, the drama of Mexico's past.

Diego Durán, O.P.

Among the friars the Dominican Diego Durán supplies us with unique evidence of the pre-Conquest use of mushrooms in his superb *Historia de las Indias de Nueva España*. (I shall use the two volume text edited by Father Garibay, 1967.) This work was written in the 16th century and survives in the author's own manuscript. Here is a remarkable account of the history of the Aztecs, an account that no Spaniard could have assembled on his own, an intimate inside story of the rulers of Mexico-Tenochtitlan, their entourage, their traditions and practices, their wars, religious beliefs, diversions, successes and failures. Durán cites constantly the '*Historia*' that he is using or sometimes certainly translating, and scholars seem agreed that when he wrote he had before him a narrative in Nahuatl but in Latin characters written or dictated by someone highly placed in the pre-Conquest regime who had enjoyed the confidence of the sovereign and who was steeped in the oral traditions of his people. This unidentified personage, intelligent and able, was clearly a partisan but as we do not possess comparable narratives by others, scholars can usually do no other than let his stand alone. As its author concerned himself solely with the doings of the kings and aristocrats, he tells us only by inference about the conditions of the farmers, the artisans, and the women folk. This '*Crónica X*' (as it is called) may still exist and its discovery would be a sensational event in Mesoamerican studies.

According to *Crónica X*, in the festivities following the coronation of the sovereign Tizoc in 1481, at the end of the great banquet, inebriating mushrooms were served to the guests. Durán does not say whether this had happened on the occasion of previous coronations but from his context it seems probable that it was habitual on all grand occasions. Here is what Diego Durán writes:

> 40. Y todos los señores y grandes de las provincias se levantaron y, para más solemnizar la fiesta, comieron todos de unos bongos monteses, que dicen que hacen perder el sentido, y así salieron todos muy aderezados al baile.

> [II Cap XL 40]
>
> And all the lords and grandees of the provinces rose and, to solemnize further the festivities, they all ate of some woodland mushrooms, which they say make you lose your senses, and thus they sallied forth all primed for the dance.

Tizoc's reign was a failure: he was pusillanimous and he died, probably poisoned (according to *Crónica X*), in 1486, whereupon his brother Ahuitzotl was elected his successor.

Not a word is said about mushrooms in the detailed and glowing account of Ahuitzotl's coronation feast, but in an important aside that Diego Durán makes on the text before him we gather by implication the general rôle played by the mushrooms on all such occasions. (This citation has been mentioned in Chap 5, p 95).

> 16. He notado una cosa en toda esta historia: que jamás hace memoria de que bebiesen vino de ningún género para embriagarse, sino sólo los hongos monteses, que los comían crudos, con los cuales, dice la historia, que se alegraban y regocijaban y salían algo de su sentido, y del vino nunca hace memoria, sino es para los sacrificios o mortuorios; sólo hace memoria de la abundancia de cacao que se bebía en estas solemnidades.
> [II Cap XLII 16]
>
> One thing I have noticed in all this *Historia* [= *Crónica X*]: that never is mention made that they drank wine [*ie* fermented drinks] of any kind to get drunk, but only the woodland mushrooms which they ate raw, with which, says the *Historia*, they would rejoice and grow merry and become somewhat tipsy; and mention is never made of wine save only for sacrifices or funerals; mention is made only of the abundance of chocolate that would be drunk on these exalted occasions.

In this pregnant aside Durán is telling us several things:

a. by strong implication the *Crónica X* speaks often of inebriating mushrooms but Durán as editor has chosen to omit all save four or five such citations and he is now summarizing all the references that lay before him;
b. he observes that fermented drinks were never taken with the mushrooms: fermented drinks were beneath the dignity of the Aztec aristocrats on occasions such as Durán is describing. (The Aztecs tried to confine the use of fermented drinks to the superannuated men and women whose active rôle in life had ended.) It seems to have been considered an offense to pollute the pure effect of the mushroom inebriation with alcoholic inebriation; and
c. an abundance of chocolate was however consumed in these great banquets: chocolate was a beverage served cold with maize, *poyomatli*, other flowers, and almost certainly spiked with the juice of entheogenic mushrooms or an infusion of ground morningglory seeds.

We come now to the coronation of Moctezuma II in 1502 when no one in the Aztec country had yet heard of the Spaniards. For four days there was feasting and celebration and then on the fourth day came the coronation followed by human sacrifices in numbers. Then follows this paragraph where the sacred mushrooms enter:

> 24. Acabado el sacrificio y quedando las gradas del templo y patio bañadas de sangre humana, de, allí iban todos a comer hongos crudos; con la cual comida salían todos de juicio y quedaban peores que si hubieran bebido mucho vino; tan embriagados y fuera de sentido, que muchos de ellos se mataban con su propia mano, y, con la fuerza de aquellos hongos, veían visiones y tenían revelaciones de lo porvenir, hablándoles el demonio en aquella embriaguez.
> [II Cap LIV 24]
>
> The sacrifice finished and the steps of the temple and patio bathed in human blood, they all went to eat raw mushrooms; on which food they all went out of their minds, worse than if they had drunk much wine [*ie* fermented drinks]; so drunk and senseless were they that many killed themselves by their own hand, and, with the force of those mushrooms, they would see visions and have revelations of the future, the Devil speaking to them in that drunken state.

Durán's tone here is so out of harmony with what he had previously said that, were we not dealing with the holographic manuscript in his own hand, I would ask whether we had to do with an interpolation of a priestly redactor. Such a violent statement - many men drunk and senseless killing themselves! - is repeated by white men unacquainted with the hallucinogenic mushrooms, or who have possibly been ill-prepared for the experience and been drunk from alcohol when they took them. In Father Garibay's three volumes of *Poesía Nahuatl* we see time and again the glowing ecstasy, the awe-struck and reverential attitude, of the Nahuatl aristocrats, speaking to us in person about the wondrous mushrooms.

The coronation of Moctezuma is the occasion for another passage strange for us, founded on *Crónica X* but with Durán's comments added, in which we learn that the princes and lords of the enemy states were invited to the festivities and that they accepted the invitation, where among other items on their social agenda, they witnessed from specially built blinds the sacrifice on one of the lofty pyramids of their own kin and compatriots captured in past 'wars'. Here we see to what extent those 'wars' were purely ceremonial, to capture prisoners for sacrifice. Afterwards Moctezuma sent the enemy delegations home laden with jewels and other presents, and he gave them powerful escorts back to their own borders so that they would not be waylaid as hated enemies by Aztecs or their allies. [See II LIV 23; also XLII 17 and elsewhere.]

Such passages in the chronicles of the Aztecs astonish us: the number of human sacrifices that are set forth in detail, the way in which they are keyed to the religious calendar, the variety of methods used in taking the lives of the victims many of them cruel taxing belief and, perhaps strangest of all, the presence at their deaths, on the invitation of the victorious Aztec king, of their kin and friends. All these elements leave us in a quandary. A well known mycologist has expressed the view that the victims, to prepare them for sacrifice, were fed massive doses of mushrooms:

> Il devient compréhensible maintenant comment les fêtes sacrificielles de l'ancien Mexique ont pu ne susciter aucune défense des milliers de victimes humaines choisies qu'on y sacrifiait de manière cruelle et sanglante: elles obtenaient la pleine coopération des victimes, selon toute apparence après des orgies massives de champignons.
> [*Bulletin Suisse de Mycologie*, June 1958]
>
> It now becomes comprehensible how the sacrificial feasts of ancient Mexico were unable to provoke any defense from the thousands of chosen human victims that were sacrificed in a cruel and bloody manner: they won the full cooperation of the victims, according to all appearances after massive orgies of mushrooms.

There is no support for this conclusion in either Durán's *Crónica X* nor in the testimony of Sahagún's Nahuatl informants nor anywhere else. This mycologist was giving circulation in a scientific journal to his own idle fancies. He did not know his sources, readily available though they were to him.

A point has now been reached in Mesoamerican research where we can begin, hesitatingly and with all reservations, to sum up this advanced culture of Early Man, evolved out of its own innards, with no sure trace of external influence, and define the outlines of its distinctive even though unexpressed objectives. Their intelligent and thoughtful leaders might not have formulated the objectives in my terms but I think these were at least subliminal in all that they did.

The highest goal of Mesoamerican Man, his greatest achievement, was to display physical and moral courage in the face of imminent death. Those mushrooms, had the victims eaten of them, would have deprived their behavior of merit: it would have been cheating. Imminent death may also have confronted the winner in the Maya ball game, when I think he would proudly rise to the occasion. The prospect of imminent death, always a possibility, lies like a shadow over the thinking of the poets that Father Garibay has given us. The presence of their kin and compatriots at their sacrifice must have imbued these victims with pride as they climbed the long, steep, shallow steps without balustrade of the pyramid to meet death when they reached the top. The enemy delegations, sad though they were, were a moral support for them and made their courageous behavior easier. We must not forget that slaves scheduled for sacrifice, from the moment when they were chosen and dedicated to the gods, received honored treatment, being given the best of clothing, the best of foods, and treated with utmost respect. Tlaxcala and that city's allies were habitual losers to the Aztecs at the moment of the Spanish conquest, but there is every reason to think that, if the tide had been reversed, they would have inflicted identical penalties on the Aztecs.

In accounts of the native North Americans I have read that prisoners destined to die would take pride in taunting their captors, insulting them ingeniously to infuriate them, even as their captors were torturing them and slowly putting them to death. May not this practice, where physical courage in face of certain death was exalted to the highest degree, have found its supreme, most sophisticated expression in the religious sacrifices of the Mesoamericans?

Moctezuma in his pride tried to carry yet further his ambivalent relations with those who were his enemies though his efforts were unsuccessful:

> 27. Desde este día, cuenta la historia, que tres veces en el año convidaba Motecuhzoma a los reyes y señores enemigos y les hacía gran fiesta. La una era en la fiesta que ellos llamaban de los señores, y la otra en la gran fiesta de las banderas, y la otra, cuando comían todos hongos, que la llamaban la fiesta de las revelaciones. Las cuales fiestas hallarán en la Segunda Parte de este libro [Vol 1 of this edition] escritas a la larga.
>
> 28. Este orden tomó Motecuhzoma de convidar a sus enemigos, el intento del cual no lo pone la historia; empero, concluiré con decir que Motecuhzoma convidaba a sus enemigos; lo cual no hicieron los demás reyes sus antepasados, sino sólo su abuelo el primer Motecuhzoma. La cual costumbre duró mientras reinó. Y lo mismo guardaron los tlaxcaltecas en convidarle a él a sus solemnidades y a las veces iba o enviaba sus grandes; iban sin ser sentidos de sus gentes, ni de los tlaxcaltecas, aunque, según la historia, muy pocas veces fue él en persona, ni se halló en estas fiestas ni solemnidades.
> [II Cap LIV 27, 28]
>
> From this day on, according to the *Historia*, three times a year Moctezuma would invite the enemy Kings and Lords and give them a big feast. One. was the feast that they called 'of the Lords', and the other was the great 'Feast of the Flags', and the other when they would all eat mushrooms, which they would call the 'Feast of the Revelations'. The which feasts will be found in the Second Part of this book written out at length.

Moctezuma took this decision to invite his enemies, but the History does not say what his intention was; however, I shall conclude by saying that Moctezuma invited his enemies, which was not done by the other kings his predecessors, save only by his grandfather the first Moctezuma. The which custom lasted as long as he reigned. And the same observed the Tlaxcaltecas inviting him to their solemnities, and sometimes he went or sent his grandees; they went without their people's noticing it, nor the Tlaxcaltecas, although, according to the History, very seldom did he go in person, nor did he attend the festivities nor the solemnities.

The Feast of the Lords and the Feast of the Flags are indeed described in what Durán calls the second part of his book. (In Father Garibay's edition he has reversed the two volumes, so that the relevant Chapters XI and XIII are now in his Vol 1.) But the Feast of the Revelations, 'when they would all eat mushrooms', is alas missing in its entirety. Was it perhaps suppressed by Durán's religious superiors? This lost section of *Crónica X* would certainly have proved an invaluable document for us.

There is one further reference to mushrooms in Durán:

> 26. [Moctezuma] después de estos oráculos y plegarias, hacía comer a los viejos y sacerdotes antiguos, hongos verdes y otros brebajes supersticiosos, que les hacía beber, para que supiesen en aquellas embriagueces que aquellas comidas y brebajes les causaban, de tener victoria o no. Y desdichados de los que le anunciaban mal suceso, porque luego eran mandados matar, sin ningún remedio.
> [II Cap LXV 26]

> [Moctezuma] after these oracles and supplications, made the old men and former priests eat *green* mushrooms and other superstitious potions that he made them drink, so that they would learn in those drunken states that were caused by those foods and potions whether he would win victory or not. And woe betide those who predicted a bad outcome, for forthwith he ordered them to be killed without help for it... [Italics mine]

'Green mushrooms': we already know what the green mushrooms are, the sacred ones, which in paintings are green to suggest the most valuable of jewels, the rings of jade.

Bernardino de Sahagún

The Dominican Diego Durán and the Franciscan Bernardino de Sahagún towered above the other friars in sixteenth century Mexico in their intellectual curiosity about the natives, their history and culture. According to Father Garibay, they almost surely sprang from Jewish families lately converted to Catholicism. If so, it must be no mere coincidence that these two able men devoted their lives to the study of the conquered and downtrodden race. Sahagún spent more than half a century taking down in Nahuatl the testimony of numbers of carefully selected informants - selected for their knowledge and connections - and in 'rendering' or paraphrasing (not translating) in a Spanish *versión* their depositions. The Sahagún corpus is immense, only now coming to be fully known. It lies in Madrid and in the Biblioteca Laurenziana in Florence. The *Florentine Codex*, as this latter manuscript is commonly called, is bilingual, the Nahuatl depositions with Sahagún's rendering, profusely illustrated. In the 1960's Dr Charles E. Dibble and Dr Arthur J. O. Anderson brought to term the immense task of translating the Nahuatl text into English and the University of Utah published it in thirteen large volumes, the Nahuatl text and their English translation in parallel columns.

In the light of its size, what is contained in the Sahagún corpus about the hallucinogens and the mushrooms in. particular is meager, and what there is seems written with studied detachment leaning on the pejorative side. Here is nothing of the free flowing enthusiasm of the Nahuatl poets rendered for us by Father Garibay, but we must also point out Sahagún does not indulge in vituperative condemnation of the sacred mushroom such as we see in the writings of Motolinía and De la Serna. The longest passage that Sahagún's informants ever give us of the formal use of mushrooms is in an account of a celebration of some prosperous merchants who are making a displ ay of their wealth in their neighborhood. We are grateful to Dr Dibble and Dr Anderson for having granted us permission to offer our readers their translation of this and other passages relating to the mushrooms, which are mostly new to the scholarly world. Here is the Nahuatl account of the merchants' mushroom celebration put into English:

> At the very first, mushrooms had been served. They ate them at the time when, they said, the shell trumpets were blown. They ate no more food; they only drank chocolate during the night. And they ate the mushrooms with honey. When the mushrooms took effect on them, then they danced, then they wept. But some, while still in command of their senses, entered [and] sat there by the house on their seats; they danced no more, but only sat there nodding.
>
> One saw in vision that already he would die, [and] there continued weeping. One saw in vision that he would die in battle; one saw in vision that he would be eaten by wild beasts; one saw in vision that he would take captives in war; one saw in vision that he would be rich, wealthy; one saw in vision that he would buy slaves - he would be a slave owner; one saw in vision that he would commit adultery - he would be struck by stones - he would be stoned; one saw in vision that he would steal - he would also be stoned; one saw in vision that his head would be crushed by stones - they would condemn him; one saw in vision that he would perish in the water; one saw in vision that he would live in peace, in tranquillity, until he died; one saw in vision that he would fall from a roof-top - he would fall to his death. However many things were to befall one, he then saw all in vision: even that he would be drowned.
>
> And when the effects of the mushrooms had left them, they consulted among themselves and told one another what they had seen in vision. And they saw in vision what would befall those who had eaten no mushrooms, and what they went about doing. Some were perhaps thieves, some perhaps committed adultery. Howsoever many things there were, all were told - that one would take

> captives, one would become a seasoned warrior, a leader of the youths, one would die in battle, become rich, buy slaves, provide banquets, ceremonially bathe slaves, commit adultery, be strangled, perish in the water, drown. Whatsoever was to befall one, they then saw all [in vision]. Perhaps he would go to his death in Anauac.
> [*Florentine Codex*, Dibble & Anderson, Bk 9 pp 38-39]

The Nahuatl original differs in one striking particular from Sahagún's Spanish rendering in the familiar Florentine text: the Codex says explicitly in Spanish that the mushrooms *aúm provocan a lujuria*, they 'even provoke lust'. This is an interpolation for which there is no justification in the Nahuatl source. Was Sahagún responsible for adding these words? Why were they inserted? To excite the sixteenth century readers seeking always the Fountain of Youth and new aphrodisiacs? Or to incite his pious readers against the mushrooms?

The well known passage where Sahagún in the *Florentine Codex* uses the word *teonanácatl* appears afresh in the Dibble & Anderson translation of the Nahuatl:

Nanacatl

> It is called *teonanácatl*. It grows on the plains, in the grass. The head is small and round, the stem long and slender. It is bitter and burns; it burns the throat. It makes one besotted; it deranges one, troubles one. It is a remedy for fever, for gout. Only two [or] three can be eaten. It saddens, depresses, troubles one; it makes one flee, frightens one, makes one hide.
> He who eats many of them sees many things which make him afraid, or make him laugh. He flees, hangs himself, hurls himself from a cliff, cries out, takes fright. One eats it in honey.
> I eat mushrooms; I take mushrooms.
> Of one who is haughty, presumptuous, vain, of him it is said: 'He bemushrooms himself'.
> [*Ibid* Bk 11 p 130]

Book 10 of Sahagún's *Historia General*

In Dibble & Anderson's translation of Book 10 we discover five references to the inebriating mushrooms where none is cited in the Spanish rendering. These five citations are parallel: indeed they resemble each other so closely that one asks oneself whether they were not dictated by the same informant. Much of this Book 10 is given over to a particular kind of exercise, primarily linguistic: scores of types of people are succinctly abstracted - people chosen by their occupation, worthy and unworthy, by kinship rôles as *eg* the 'grandmother', by social rank, *etc*: hundreds of such types are offered to us. Until Dibble & Anderson gave us their translation, this wealth of information about the Nahuatl vocabulary and the Nahuatl social organization was accessible to us only in the inadequate Spanish *versión* of the *Florentine Codex*. Here follows a mere sprinkling of the hundreds of individuals described:

The lazy mother
The goldcaster
The maguey syrup seller
The mason with plumb
The bad farmer
The good nephew
The sodomite
The seller of salt
The green stone seller
The seller of tamales
The bad nobleman
The buffoon
The lapidary
The harlot
The thief

The reader of these abstractions inevitably thinks back to that minor form of literature known to the literary historian as 'Characters', first delineated by Theophrastus in ancient Greece and developed most subtly in the seventeenth century by Jean de la Bruyère in France and Sir Thomas Over bury in England. These two men came after Sahagún and one may assume that he did not know Theophrastus. Sahagún was simply intent on finding ways to elicit systematically from his informants an immense range of vocabulary that would otherwise have escaped him, and a range of social circumstance that will prove an inexhaustible mine for scholars to pore over. Here then is one character:

Noblewoman

> The noblewoman [is] of nobility, belongs to the order of rulers, comes from rulership whether she

> is legitimate or a bastard child.
> The good noblewoman [is] one who is bashful, ashamed [of evil], who does things with timidity, who is embarrassed [by evil].
> She is embarrassed [by evil]; she works willingly, voluntarily.
> The bad noblewoman [is] infamous, very audacious, stern, proud, very stupid, brazen besotted, drunk. She goes about besotted; she goes about demented; she goes about eating mushrooms.
> [*Ibid* Bk 10 p 49]

The Harlot; the Carnal Woman is described at length. Put briefly, she is the whore of the itching buttocks. She lives like a bathed slave, acts like a sacrificial victim,[32] goes about with her head high - rude, drunk, shameless, eating mushrooms. [*Ibid* p 55] *The Lewd Youth* is a drunkard, foolish, dejected; a drunk, a sot. He goes about eating mushrooms. [*Ibid* p 37] *The One of Noble Lineage* when he is a bad nobleman is a flatterer - a drinker, besotted, drunk. He goes about becoming crazed on both kinds of Daturas; he goes about eating Daturas and mushrooms. He becomes vain, brazen. [Ibid p 20] *The Bad Youth* goes about becoming crazed on both kinds of Daturas and mushrooms; he is dissolute, mad; he goes about mocking, telling tales, being rude, repeating insults. [*Ibid* p 12)

From these citations we learn that the inebriating mushrooms had been abused under the old regime, as would be natural in any community freely using them. By accepted standards of the Nahua and other Mesoamericans, the mushrooms were imbued with sanctity and were to be ingested only where the glow of religious belief accompanied the act. In our five citations the repellent context was fortunate for Sahagún's informants: they could truthfully and gladly excoriate those who in former times had abused the mushrooms, and the friars would also approve such excoriation though they naturally were condemning all use of the mushrooms as a mortal sin, trafficking with the Devil. Even if friars as intelligent as Diego Durán and Sahagún were asking themselves searching questions about what the inebriating mushrooms really did, they could not afford to experiment with them, especially so if Father Garibay is right in thinking they were of Jewish origin: this racial origin must have been known to their conventual colleagues and extreme circumspection must have been the undeviating rule of their lives.

There remains one further citation of mushrooms in Book 10: in the description of *The Smoking Tube Seller*, the tobacco tube seller. (This would correspond to our tobacco pipe dealer but our tobacco pipe differs so much in appearance from the tobacco tube of the Nahua that Dibble & Anderson are well advised not to use our misleading term in their translation.) At the end of the description, which is rather lengthy, the informant gives a list of the ingredients that the seller offers with the tobacco for the 'tube'. [*Ibid* p 88] Amongst others there are mushrooms and *poyomatli*, the flowers of *Quararibea funebris*, with which we are already familiar. In my own experience in Mesoamerica I had not known that the sacred mushrooms were smoked and was sceptical when I read in Carlos Castaneda's *The Teachings of Don Juan* (entry for Sunday 10 Sept 1961) how Don Juan added los *honguitos* to his pipe mixture. Now there is the best of authority for Castaneda's text.

The holy office of the inquisition

In the notes at the end of Dr Aguirre Beltrán's *Medicina y Magia* there is a wealth of references to the court records of the Inquisition held in the Archivos Generales de la Nacion (= AGN) dealing with hallucinogens and in my files I hold copies of many of the cases that he cites. One arresting fact emerges from these files of the Inquisition: Spanish housewives of the lower classes seem to have consulted the hallucinogens often, not personally, but through their Indian servants and slaves who would know the *curandero* to consult, the hallucinogen to take. In my perusal of these files lasting for weeks I found no evidence that any Spaniard, male or female, had ingested the mushrooms but that many of them did not hesitate to enlist a surrogate from among the Indians. To this generalization there was one possible exception.

---

[32] Those selected for sacrifice were honored in the community, and went around well dressed, eating expensive food, carrying their heads high. See p 203 for further mention of this.

1

The earliest reference to the sacred mushrooms in the story of the Conquest came in 1537, when the first Bishop of Mexico, the Franciscan Juan de Zumárraga, presided over the trial in Mexico City of two Indians, brothers, called in Nahuatl Mixcoatl and Tlaloc and in Spanish Andrés and Juan. They were charged with organizing resistance to the Spaniards, arming their fellow Indians, and invoking their Indian divinities for help in the struggle. These activities were aggravated by the fact that they had been baptized and were apostates, backsliders. They seem to have enjoyed considerable success, and as the Spaniards had been on the scene at that time for only two decades, the rulers may well have been fearful of an uprising. The record is lengthy and the mushrooms are mentioned five times, each time briefly, as though the Spaniards were not altogether familiar with them, but the Spaniards knew well that the mushrooms were served by the Indians in what they considered a simulacrum of the Holy Eucharist. The brothers were convicted and sentenced: they were to be mounted on asses or other beasts of burden equipped with packsaddles, they were to be paraded through Mexico City, Tulantzingo, and other centers where they had carried on their agitation, and each was to receive one hundred l ashes in each community, with a crier going before proclaiming their offense. Their hair was to be shorn, they were to renounce their heresies, and they were to be remanded for a year to live in the monastery of Tulantzingo, listening to the Doctrine and doing penance for their misdeeds. Their property was to be sold for the benefit of the Exchequer of the Holy Office. All this having been done, the Guardian Father of Tulantzingo was empowered to absolve them and reconcile them to Holy Mother Church.

This trial must have caused a stir among the Indians at the time. The sacred mushrooms figure in it certainly but it would be a mistake to exaggerate their importance. The gravamen of the charge was that the accused were apostates stirring up the Indians with inflammatory talk, denouncing the Spaniards, mobilizing arms, encouraging rebellion, and professing the power of the gods of the old religion. But the Holy Office was fully aware of the parallel between the bread and wine of Holy Communion - the flesh and blood of Christ - and the mushrooms that, according to the Indians, gave them visions.

In the light of the terrifying cruelties inflicted commonly on prisoners in the sixteenth century, let it be noted that Andrés and his brother Juan came off lightly. [Archivo General de la Nación: Vol III *Procesos de Indíos, Idolatrias y Hechiceros* pp 53-78, Mexico City, 1912]

2

The files of the Inquisition disclose another episode, amusing as well as instructive, that took place in 1629 in Michoacán, some distance west of Mexico City. A young woman named Inés Martín had left her husband Gonzalo. In despair he sought her in the woods. There he met an Indian named Joseph who advised him to ingest certain mushrooms (*raíces* = roots) that would reveal her to him in a vision. He followed this advice with startling effect: they showed her to him in a vision half a league away, underneath a tree in a garden where a relative was delousing her. It is noteworthy that no one disputed the miraculous power of the mushrooms: the inquisitor himself tacitly accepted the story as told. The gravity of the case was not Gonzalo's credulity but that he had recourse to the Devil for a miracle. Gonzalo may have been entirely Spanish in origin, and if so, he is the first and only known instance where a non-Indian ingested the mushrooms until the Wassons came on the scene in 1955. Still today the mushrooms serve to find objects or animals or persons that one seeks, and here we have, in testimony before the Inquisition in 1630, a classic instance of this kind. The translation of some of the testimony of Gonzalo follows:

> In the town of Taximaroa, 11 May 1630, before Father friar Cristoval de Vaz, Commissary of the Holy Office of the Inquisition in this jurisdiction... at about 4 o'clock in the afternoon, there appeared without having been summoned and duly sworn to tell the truth a man who said that his name was Gonzalo Pérez and that he was married to Inés Martín, both domiciled in this town... who to clear his conscience accused and denounced himself in this wise: he says that about two years ago, his wife having fled from him, and as she was his first love he was profoundly touched by her absence, and going into the woods to look for her he found an Indian named Joseph, a servant of his father, who said to this witness that he would give him an herb that they call *nanacates* with which he would see where she was, and having given him two little roots he saw nothing and afterwards this witness said to this Joseph, 'Get away from me, for you are a witch for you have done nothing for me nor have I seen anything', to which said Indian said he should

> take five of those as it were roots and he would see her, and this witness without knowing what he was doing with the desire that he had to see his said wife took them at about the hour of vespers and ate them and within two hours having bedded down in the woods, he saw a snake that said to him, 'Turn your head and you will see your wife', and turning he saw her in the house of a first cousin of this witness named Petrona Gutiérrez who was delousing her, being half a league from that hacienda without being able to see said hacienda; and that this witness really saw her, and from where he was this witness went to the house of his parents and said to his mother he had seen his said wife and confessed that he had taken said herb because his mother already knew it, who threw a rosary around his neck, and said mother went in search of his said wife and she found her there where this witness had seen her and brought her to his house... He was asked whether he firmly believed that the herb had shown him his said wife and that it had been by the craft of the Devil, whereupon he said yes.
> [Audience of the Holy Office of the Inquisition, AGN, Mexico City, vol 340, fol 354-359, transcribed for us by the late Sra María de la Luz Viamonte]

3

Our third episode tells of a *curandero* who narrowly escaped the clutches of the Holy Office. A seventeenth century cleric, Jacinto de la Serna, composed a guide for priests ministering to the Indians. His work was entitled *Manual de Ministros de In dios para el Conocimiento de sus Idolatrías y Extirpación de Ellas*. He was a garrulous busybody, zealous in rooting out and extirpating all expressions of the Indians' old religion, and eager in his narrative to leave a record of his own zeal. Chapter IV of his work continues a recital of incidents that had happened to the author proving (as he says) that idolatry was still rampant among the Indians in his own time. In Section 3 of this chapter he is discussing native physicians and midwives, especially the rôle of 'witchcraft' in their practices, and certain goings on in his own household that had aroused his liveliest suspicions. A certain Indian, master of the native lore, had lately arrived in the village and had officiated at a religious rite in which the intoxicating mushrooms had been a central feature. The description of the religious ceremony reaches us through don Jacinto by hearsay only, as of course he was not present, but it carries a ring of authenticity.

> And what happened was that there had come to the village an Indian, a native of the village of Tenango, great master of superstitions, and his name was Juan Chichitón, which means 'little dog', and he had brought the red-colored mushrooms that are gathered in the uplands, and with them he had committed a great idolatry, and before I tell of it, I wish to describe the property of said mushrooms, which are called in the Mexican language *Quautlannamacatl*, and having consulted the Licentiate Don Pedro Ponce de León, the great Minister and Master of Masters as I said in Chapter II, he told me that these mushrooms were small and golden, and to gather them it was the custom for the priests and old men deputized as ministers for this kind of hum buggery to go up into the mountain, and they remained almost the whole night in prayer and superstitious entreaties, and at dawn, when there sprang up a certain breeze that they knew, then they gathered the mushrooms, attributing divinity to them, possessing as they did the same effect as *ololiuhqui* [*Turbina corymbosa* (L.) Raf.] or peyotl [*Lophophora Williamsii* (Lem.) Coulter], because whether eaten or drunk, it intoxicates them and deprives them of their senses, and makes them believe a thousand foolish things. And so this Juan Chichitón, having gathered the mushrooms on a certain night, in the house where everyone had gathered on the occasion of a saint's feast, the saint was on the altar, and the mushrooms with *pulque* and a fire beneath the altar, the *teoponastli* [a percussion instrument peculiar to Mesoamerica] and singing going on the whole night through, after most of the night had passed, said Juan Chichitón, who was the priest for that solemn rite, to all those present at the fiesta gave the mushrooms to eat, after the manner of Communion, and gave them *pulque* to drink, and finished off the festivities with an abundance of *pulque*, so that what with the mushrooms on the one hand and the *pulque* the other, they all went out of their heads, a shame it was to see.

De la Serna goes on to relate how he had made utmost efforts to ferret out and lay his hands on Chichitón. There was a hot chase, but by the skin of his teeth the 'Little Dog' eluded his pursuer's clutches.

The mycophobic syndrome: our supreme example

Our book has undertaken to show how the White Man at first tried to play down, then ignore, the entheogenic mushrooms of Mesoamerica, until, having fully accomplished this purpose, even the scholars specializing in the field, spokesmen as it were for our Western civilization, did not give them a thought. Here follows an enlightening illustration of this mental block from the very citadel of Mesoamerican studies.

In the late 1920's there was found lying in the library of the University of Texas, a manuscript entitled:

Coloquio de la nueua conbersion y bautismo
de los cuatro últimos reyes de Tlaxcala

'*Colloquy* of the new conversion and baptism
of the four last kings of Tlaxcala'

The 'Colloquy' is written in crude verse, a piece of religious propaganda devoid of literary merit. The participants in the 'Colloquy' are twelve: Hernán Cortés Marqués del Valle and his interpreter Marina, two 'Ambassadors', the cleric Juan Diaz, the four 'kings' (as they are called) of Tlaxcala, *Hongol demonio ydolo*, and two angels who raise their voices in triumphant singing as the four 'kings' are baptized with Christian names suggested by Cortés. The utterances of the four 'kings' are saturated with talk of *Hongol*: at first they are under *Hongol's* domination but they lend themselves readily to conversion and baptism. Though *Hongol* delivers three lengthy speeches, he of course loses out to the Christian appeals. The manuscript bears the date 1619 which gives us a *terminus ad quern*: it was composed in the early seventeenth century or the final years of the sixteenth.

Hongo is 'mushroom' in Spanish and it takes no perspicacity to see that *Hongol*, the Demon and Idol, is our *teonanácatl* or *xochinanácatl*.

Whether this 'Colloquy' was ever performed we do not know. But this 'Colloquy' does declare and ratify one lesson that our book brings out: the preoccupation of the friars for generations after the Conquest with the divine mushroom (as the Nahua called it), a powerful rival to the Holy Eucharist.

> Bastará decir que los cuatro reyes, como el autor los llama, hablan a la continua de un dios ONGOL, HONGOL, perfectamenta desconocido en Tlaxcala y en todo sitio en que se habla nahuatl, pues sabido es que esta lengua carece de G. [pp 157-159]
>
> Suffice it to say that the four kings, as the author calls them, speak continually of a god *ongol*, *hongol*, completely unknown in Tlaxcala and everywhere else where Nahuatl is spoken, since it is well known that this language lacks the letter G.

Father Garibay did not see that *hongol* was simply a translation of *teonanácatl* with the terminal *l* of Nahuatl added. The sacred mushrooms of the Nahua were absent from his mind. But how much did he differ from other Mesoamerican specialists?

In 1843 Prescott, in his *Conquest of Mexico*, omitted all mention of the sacred mushrooms. In 1898 Carl Sapper and also Daniel Brinton showed that they had never heard of the mushrooms in Mesoamerica. Walter Lehmann, when he edited the *Codex Vindobonensis* in 1929, remarked on the resemblance to mushrooms of the curious objects therein portrayed, but it did not occur to him that they might be what they looked like: he had failed to note the mushrooms in the writings of the friars. Father Garibay, reaching the height of his scholarly activities in the fifties, did not perceive the *teonanácatl* of the Nahua when editing his Sahagún (published in 1956), when he commented on the seventeenth century *Colloquy* featuring '*hongol*', nor ten years later when editing his *versión* of the Nahuatl poets in the 1960's. He did not know about the worries of his fellow clergy and their struggles against what they had considered the travesty of the Holy Eucharist that the Indians were accustomed to perpetrate with mushrooms. Indeed, did he not learn of the existence of the sacred mushrooms of the Nahua from the publicity that attended the discoveries of Heim and the Wassons?

Alfonso Caso, albeit with some reluctance, was the first and only Mesoamerican scholar to concede recognition to the potent entheogenic mushrooms in his paper on the *Codex Vindobonensis*. In it he declared at the outset that the paper owed its genesis to Heim and the Wassons. Even that paper of Dr Caso's, which appeared fifteen years ago, has had no reverberations in scholarly circles.

Safford's blunder in 1915 drew no protests from eminent scholars or scientists. Reko's persistent protests fell on deaf ears and he died a disappointed man in 1953. Weitlaner's efforts, and Jean Bassett Johnson's, and Schultes's passed unnoticed, perhaps because of the war. Until Valentina Pavlovna and I assembled and recapitulated their activities in an article that appeared in the *Journal* of the New York Botanical Garden, Jan-Feb 1958, few thought of them or of *teonanácatl*. Sahagún, Diego Durán, De la Serna, Motolinía, Hernández, *etc etc* - they might as well not have mentioned mushrooms. The sacred mushrooms of the Mesoamericans had fallen into oblivion. Safford was victorious, almost.

Strange, how most Mesoamerican scholars slough off as of no interest to them (or us!) an area of experience that for thousands of years irradiated the lives of the people they study. Our original and daring and eccentric hypothesis, my wife's and mine, that the peoples of Western Europe (except those speaking Catalán and the *langue d'oc*) were steeped from birth in darkest mycophobia to the point where their minds, all unawares, were invincibly closed to mushrooms, may well have been right! To my amazement, let it be said: was ever wild conjecture more stunningly ratified than ours by the extraordinary Mesoamerican evidence? But our strictures are not confined to Mesoamerica. The use of fungal entheogens was once circumpolar. The Claviceps at Eleusis, the fly-agaric linked with birch and conifer, and also (increasingly probable) with the famous Soma of the Aryans, along with the *teonanácatl* of Mesoamerica, seem to have evoked boundless awe and obeisance from our Eurasian ancestors and their New World descendants.

The range of mushroom use in mesoamerica

In Fig 1 we off er our readers a map of the areas over which I think it is fair to say that the cult of the divine mushroom probably prevailed at the moment of the Conquest. This is an approximation, perhaps on the conservative side. The map is built on linguistic areas as those areas probably stood in the fifteenth century. Trade was flowing constantly throughout Mesoamerica, the merchants travelling with their stocks of goods on their backs and, for mutual protection, in bands. There was also warfare in which slaves and goods were captured. It stands to reason that throughout this cultural area the mushrooms were known and used wherever they grew and perhaps slightly beyond. Their fame must have been wider than their use. There was no secrecy about the mushrooms. How could there be?

1. *The Nahua* in the Valley of Mexico have left us rich documentation on their use and abuse of inebriating mushrooms and the exalted status accorded to them by the aristocrats. Father Garibay in his rendering of the two anthologies in his *Poesía Nahuatl* 1-3 leaves us in no doubt about this and Diego Durán in brief but pungent references is in agreement. The Nahua were widely distributed over what is now central and southern Mexico and bands had emigrated to Guatemala on the Pacific Coast and into the Highlands where they were known as Pipil.

2,3,4. *The Otopamean* linguistic group: *Otomí*, *Matlatzinca*, *Mazahua*. In *Les Champignons hallucinogènes*... (1958) I traced back to 1543 the evidence for the use of the mushrooms in Otomí country and also cited an Otomí lexicon dated 1640 in the Biblioteca Nacional de México that cites Otomí words for the inebriating mushrooms. Karl-Herbert Mayer of Graz has lately discovered an Otomí lexicon in the Bibliothèque Nationale (Paris) dated 29 October 1605 giving similar words for the inebriating mushrooms in that language: these are both manuscripts, and the 1640 dictionary may have been copied from the original of the 1605 version. No one seems to have reported a present day use of the sacred mushrooms: perhaps no one has looked for it.

Similarly in the Matlatzinca country, in *Les Champignons hallucinogènes*, a manuscript lexicon of 1642 composed by Diego Basalenque lends support for the use there of the mushrooms. We called attention also to a document of 1579 that recorded the payment of tribute in kind in the old days to the Lord of Mexico, and among those deliveries were mushrooms. One anthropologist has drawn attention to the fact that in the records of tribute paid in kind under the kings of the Aztecs mushrooms are never mentioned. He had overlooked this passage, but it is true that so far as we now know it is unique. Is not the explanation simple? When we went down to Mexico in 1953 and began our exploration of the mushroom complex, we discovered that mushrooms did not figure in the market squares: they changed hands privately, they were carried out of sight through public thoroughfares, one did not speak of them. Was not this even truer in the old days before the Conquest?

The Matlatzinca language survives to this day in one town: San Francisco Oxtotilpan. Dr Gastón Guzmán and A. López-González, the former a mycologist and the latter an anthropologist of the Escuela Nacional de Antropología e Historia, succeeded in documenting the use of *Psilocybe Wassonii* among the inhabitants of that village. Leonardo Manrique, Chief of the Department of Linguistics of the Museo Nacional de Antropología, says that the name of these mushrooms in Matlatzinca today is *neto&ccaron;*^{h}*utata*, *ne-* being the plural, *-to-* a reverential diminutive, *-&ccaron;*^{h}*u-* the root for sacred, and *-tata* being lord; 'the most holy little Lords'.

For the Mazahua, we have no contemporary information. Robert Weitlaner and I visited them briefly but failed to arrive at any positive information. On the other hand in *Mushrooms Russia & History* we cited a manual prepared in Mexico and published in 1637 entitled *Doctrina y Enseñanza en la lengua Maçahua de Casas muy Utiles, y Provechosas para las Ministros de Doctrina* by the Licentiate Diego de Nágera (or Nájera) Yanguas, incumbent of Xocotitlan. This is a manual to guide the clergy serving the Mazahua population and specifically guiding them in asking questions of the faithful in the confessional. The Father confessor on folios 27-29 catechizes his penitent as to whether he has eaten mushrooms and got drunk on them and if so why, whether to find lost objects or for illness. The following extract shows the tenor of the questions, the column in English being added by us:

por que	yoqhenangueze	why
querias	daguiminemaha	didst thou want
comer	toguiça	to eat
essos hongos?	mayho yocho	those mushrooms?
por que	nanguezé	because
estaba enferrno	darirniçhoye	I was ill
queria comer	dariminemaha rogoza	I wanted to eat
hongos	yocho	mushrooms
para ver	maqheranuu	to see
lo que perdi	maqhe peqherobexi	what I had lost
quantas vezes?	hançhanixi?	how often?
no los comiste?	que higuiza?	didst thou not eat them?
no los comi	hiroza	I ate them not
solamente	anguechco	I only
queria	dariminemaha	wanted
comerlos	togoza	to eat them.

Mushrooms Russia & History p 221

5. *Tarascan*. A lexicon compiled by Maturino Gilberti and published in 1559 gives the word in Tarascan for the mushroom that inebriates. Furthermore, in the episode before the Inquisition that we told at length on pp 210-211, the scene took place in 1629 in Michoacan and Joseph the Indian was presumably a native Tarascan speaker.

6. *Huastecan*. This tongue descended from the Mayan stock is spoken along the Gulf Coast, the most northern of the languages that we are ternpted to place among those using the entheogenic mushrooms. Our only written evidence is a letter discovered by Guy Stresser-Péan to the clergy of Huasteca written by the Archbishop of Mexico in 1726 in which he deplores the pagan practice of taking mushrooms and possibly other substances to obtain visions. Three of the poems in *Poesía Nahuatl* (numbers 12, 13, and 14 in Vol 3), riotous drinking songs, were said by the anthologist in the sixteenth century to be Huastecan in inspiration. In our inquiries in the mid-twentieth century we have not found the use of mushrooms in low lying territory, and as the Huasteca is partly low lying, if the practice was native there, this might extend the range of their use.

7. *Totonac*. Some linguists suggest that this language is remotely related to Mayan. It is spoken by the people living on the Gulf of Mexico south of the Huasteca. Our terra cotta figurine showing a woman with her right arm on a mushroom and her left arm raised in what I interpret as a speaking gesture, is from what is now the Totonac country but dates from the beginning of our Christian era. We assume that the Totonacs knew the mushrooms that abound there.

8. *Mixe*. We visited this area twice and found abundant evidence that the entheogenic mushrooms were known to everybody, both in the eastern stretch of the Mixe country and the western. This Mixe region is a remote and conservative country and the usage must go back long before the Conquest.

9. *Zoque*. We have not visited this area and we have no information about it, either historical or contemporary. It is contiguous with the Mixe country to the West and with the Mayan peoples to the East and North. I do not see how they could avoid practicing the mushroom cult, but as I have no information I designate it with a question mark.

10. *Mazatec*. There seems to be no historical information but we have uncovered an abundance of contemporary tradition. María Sabina has been our ever flowing source of information, and the tradition is strong and obviously ancient.

11. *Zapotec*. This major group of mutually unintelligible dialects is in an area where the inebriating mushrooms are common and where the people know them intimately. In a lexicon published in 1578 and compiled by Fray Juan de Córdoba there are words for 'mushrooms that they say give you visions'. There is additional testimony of considerable interest. It is to be found in *Paso y Troncoso: Papeles de Nueva España*, 2nd Serie, Geografía y Estadística, Vol IV: *Relaciones Geográficas de la Diócesis de Oaxaca*. The manuscript from which it was printed was dated 15 April 1580. The document begins on p 109 and deals with a Zapotec town called Teticpac, four leagues west of Antequera and 40 leagues from Tehuantepec. In the course of Paragraph XIV we read:

> Adoravan al demonio haziendo a su figura ydolos e caras de piedra muy feas a las quales sacrificavan perrillos e yndios esclauos y esta hera su adoracion e a quien tenian por dioses; e despues que hazian algun sacrifiçio tenian por costumbre bailar e ynbriagarse con vnos hongos en tal manera que vian muchas visiones e figuras espantables.
>
> They would worship the devil making in his likeness idols and faces of stone, very ugly to which they would sacrifice little dogs and Indian slaves and this was their worship and whom they took for gods; and after they had made some such sacrifice it was their custom to dance and get drunk on some mushrooms in such a manner that they would see many visions and fearful figures.

12. *Chatino*. This is a linguistic enclave in the Zapotec country. The language is called 'Zapotecan'. When Roger Heim and I went there in 1956, introduced by Bill Upson of the Instituto Lingüistico de Verano, we found many species of sacred mushrooms in use. As the Chatino country is entirely surrounded by Zapotec speakers, it is safe to assume that the practice is ancient.

13. *Mixteca*. The use of mushrooms in this important linguistic area is documented in the *Códice de Yanhuitlán* edited by Jiménez Moreno. On 15 October 1544 in proceedings before a Spanish scribe and notary, three Indians, notables, gave testimony concerning their ostentatious worship of the gods of the old religion. As they had been baptized, they were of course apostates. The principal Indian gave his testimony in Mixtec. It seems that he had taken inebriating mushrooms to invoke divine help in various circumstances. The pre-Conquest *Codex Vindobonensis* and the post-Conquest *Lienzo de Zacatepec* both include the same glyph for the sacred mushrooms. Both were Mixtec in origin. I visited the Mixteca twice, in 1960 and 1961, accompanied by Robert Ravicz and on the second occasion also by Roger Heim. Our mushroomic experiences have been published.

14. *Chinantla*. Robert J. Weitlaner and Thomas MacDougall learned of the use of inebriating mushrooms in Comaltepec and Yolox, Chinantec towns, in 1960, and in a letter to Weitlaner from Guadalupe M. Calderón, Chinantec Indian, dated 8 August 1963, he gave details about their use. Later Arthur J. Rubel and Jean Getterfinger-Krejci published a paper in *Economic Botany*, July-September 1976, submitted September 1974, giving an account of a *velada* that they had attended in Santiago Comal tepee. In that paper they also documented the use in the Chinantl a of inebriating mushrooms in the 18th century.

15. *Chantal de Oaxaca*. Evidence of a unique character seems to support the supposition that inebriating mushrooms were used in the small enclave, close by Tehuantepec, of speakers of this language classed as a Hokaltecan tongue. ('Chontal de Tabasco' is a Mayan language utterly unrelated.) Occasionally anthropologists working in remote villages in Mexico come across texts written on paper giving details, often liturgical, in the native language. They used to be most highly valued and handed down from generation to generation. When the paper was wearing out, it was recopied. No one can say how far back the text goes. Now that the hold of traditional values is breaking down, these papers are drifting into the hands of anthropologists and linguists and usually end up in the Department of Ethnology in the Museo Nacional. In the summer and fall of 1968 such a document was made available to Robert Weitlaner by Juan Ramírez, an informant who is wholly Chontal. In its text there occur the words '*mescal de hongo*': apparently the mushroom is thrown into boiling *mescal*. Later German Placencia of the Department of Ethnology found another manuscript where '*mescal de hongo*' is cited. In the light of the hold that the inebriating mushrooms have on the native peoples among whom these Chontal are living, I think we are justified in assuming that these documents refer to the use of inebriating mushrooms in the religious practices of the Chontal of Oaxaca.

16. *The Highland Mayan* languages. I have dealt with these in the preceding chapter.

CHAPTER 11

The shaman and the mushroom: new perspectives

The fascination of the Mesoamerican culture for the modern world lies in its strange (for us) traits, in the vast and ever expanding documentation permitting us to explore those traits always making discoveries, in the refinement of its thinking and its high artistic craftsmanship contrasting with human sacrifice and cannibalism on a scale unknown to us elsewhere, and in its chronological and geographical proximity to us. Here we possess an unrivalled opportunity to study Early Man in a pure culture, and also his head-on collision with sixteenth century European civilization.

How odd then is our failure until now to have grasped the hold on this culture of the entheogenic mushrooms. There was no secrecy about them before the Europeans arrived on the scene. How could there be? They grew almost everywhere in the highlands of southern Mexico. There would have been no secrecy after the White Man arrived on the scene, were it not that we, knowing nothing about them, seemed aggressively determined to learn nothing. Though living in the age of science, we regarded ourselves as inhibited from trespassing on this legitimate area of inquiry.

I have sometimes asked myself whether the unlettered ages, stretching back through æons of time, were not those belonging peculiarly to the entheogens, the Age of entheogens. The Mysteries of Eleusis began in the unlettered past of the amazing Greek people, then persisted for a few centuries under an hermetic seal of secrecy into an age of glorious letters, whereupon they finally and compl etely petered out. The Soma of the Vedic Hymns knew its heyday before the Aryans learned their letters but it disappeared with the coming of the alphabet, and it lingers on to this day among the Hindus (and some Sanskrit scholars!) only as an unsubstantial dream plant. Can these coincidences be dismissed as cases of *cum h&omacr;c ergo propter hoc*? Among the northern tier of peoples in Siberia the divine mushrooms flourished as a focus of devotion so long as they knew no alphabet, until the Russians and specifically the Soviets, precisely like the friars of Mesoamerica, tried to rub it out before studying it.

Has the advent of the alphabet with its slow progress among the languages of the world been studied in all its aspects? The coming of literacy and writing was the profound cultural event of our human civilization: this much we all know. Perhaps that event exerted a significantly different impact on different elements in the community. From my observations in Mexico, in the Algonkian country, in India, I think the unlettered herbalists possessed a body of knowledge, commanding an infinity of empirical subtleties, that has escaped our botanists and anthropologists. In the prehistory of all cultures including those still existing, the herbalists are a repository of knowledge acquired through centuries of intensive observation and experience which they pass on from generation to generation by word of mouth from master to apprentice. This was a self-contained system and largely secret. These practitioners were hardly the ones to quicken with excitement and curiosity when the talk of the alphabet was abroad in the land. On the other hand those who took to the new-fangled writing were the aggressive intellectual leaders and scribes, including sometimes priests for their own reasons and some of the aristocracy, all of them beings from a different world, and the hidden knowledge of the herbalists would hardly have come their way, their corpus of knowledge not lending itself easily to writing. Here is why Theophrastus and Dioscorides are disappointing for us: they were the heralds of the New Dawn in botany but were beginning virtually from scratch. They would have failed to win the trust of the herbalists in their midst. I am not dogmatic about these trends of long ago but am suggesting a plausible framework to explain what may have happened. The herbalists' knowledge was secret but of different degrees of secrecy. In Mesoamerica the entheogens were known to everyone, but in Greece secrecy was the rule.

In Mexico I have seen how quickly the coming of the alphabet (*ie* primary schools), the spread of literacy, changes the outlook of a village almost overnight. The old world of the *sabia*, the herbalist, the shaman, lingers on for a few more seasons in rapidly shrinking circles. Here is what María Sabina, the shaman in her eighties, said as translated from the Mazatec by Alvaro Estrada a little while ago:

> Es cierto que antes de Wasson nadie hablaba con tanta soltura acerca de los niños. Ningún Mazateco revelaba lo que sabía de ese asunto.... Los *niños* son la sangre de Cristo. Cuando los mazatecos hablamos de las *veladas* lo hacemos en voz baja y para no pronunciar el nombre que

> tienen en mazateco [*ˀnti^{1}xi^{3}tho^{3}*] los llamamos *cositas* o *santitos*. Así los llamaron nuestros antepasados.... Desde el momento en que llegaron los extranjeros... los niños santos perdieron su pureza. Perdieron su fuerza. Fueron profanados.... De ahora en adelante ya no servirán. No tiene remedio. Antes de Wasson, yo sentía que los *niños santos* me elevaban. Ya no lo siento así.
> [Alvaro Estrada: *La Vida de María Sabina*, pp 103, 119-20]
>
> Certainly before Wasson no one spoke with such freedom about the 'children'. No Mazatec would reveal what he knew on this subject.... The 'children' are the blood of Christ. When we Mazatecs speak of the *veladas*, we do so in a low voice and so as not to pronounce their name in Mazatec [*ˀnti^{1}xi^{3}tho^{3}*] we call them 'Little Things' or 'Little Saints'. Thus were they called by our forebears. From the moment when the strangers arrived the 'Holy Children' lost their purity. They lost their strength. They were profaned. From now on they will serve no purpose. There is no help for it. Before Wasson I felt that the Holy Children elevated me. I no longer feel so.

These words make me wince, but I was merely the precursor of the New Day. I arrived in the same decade with the highway, the airplane, the alphabet. The Old Order was in danger of passing with no one to record its passing. The Old Order does not mix with the New. The wisdom of the *Sabia*, genuine though it was, has nothing to give to the world of tomorrow. I think it was ever so with the arrival of the alphabet. Now the young generation is intent on the new learning, wants to forget the mushrooms that only yesterday evoked their awe, chooses the young doctor from the medical school in the city in preference to the wise-woman, and is not learning or is forgetting the language of his ancestors. Alvaro Estrada, Mazatec born in Huautla, writes me under date of 24 August 1977:

> Los jóvenes huautecos hoy día se avergüenzan de su origen indio y tratan de que sus hijos no hablen el mazateco.
>
> The young of Huautla are ashamed of their Indian origin and try to see to it that their children do not speak Mazatec.

Whether these trends are good or bad is not the question: they are inevitable.

We know that the shamanic practice of María Sabina is ancient. The evidence for this is diverse and I think overwhelming. The architectural arrangement of the immense building complexes of Teotihuacán and their murals, hitherto unexplained, make sense for the first time when interpreted by her practices. Ruiz de Alarcón's writings as illuminated by Alfredo López Austin's studies point to strikingly similar *veladas* in the Nahuatl-speaking country in the early seventeenth century, and we have listened to identical shamanic chants deep in the Zapotec country, though we did not tape them. The mushroom stones of Guatemala, the carvings of ecstatic figures of parallel age found in Mexico, the mythological genesis of the rôle for mushrooms elucidated for us in the *Codex Vindobonensis* - all speak with the same voice. We possess no starting point for this use of the divine mushrooms: the trail disappears from sight in the remotest past.

Shamanism is the term customarily used to describe one aspect of the religious life of communities, mostly preliterate, where individuals known to us as 'shamans' claim to possess, and are recognized by their neighbors as possessing, extraordinary powers for communicating with the unseen world, the world of departed spirits, which they enter through an ecstatic trance. The shamans are not organized in priesthoods: each is on his own, and the following he enlists is in proportion to the charisma that he enjoys. If, as is commonly believed, *Homo sapiens sapiens* began his domination of the world some 50,000 years ago, then it is possible, perhaps even a fair assumption that shamanism has been the highest vehicle for the expression of man's religious yearnings for more than nine-tenths of his domination of this earth, and it still survives with diminishing vigor in the world's outlying communities. If our Neanderthal (*Homo sapiens neanderthalensis*) and other predecessors were of comparable intellectual capacities, shamanism may well be far, far older.

In discussions of shamanism there has been much nonsense uttered about the rôle of inebriants. Distilled alcohol could never have been important. In the West distilled alcohol seems to have been a discovery of the School of Salemo about the year A D 1100, and it was kept a secret restricted to alchemical and monastic circles up to the Reformation four centuries later. In the East the Chinese were earlier, especially by the 'freezing-out' process, perhaps as early as the fourth century A D. But even so this is late in the long history of shamanism. I question whether fermented drinks - mead, wine, beers - were ever much used in shamanism: in most persons they cloud the brain and render muscular responses unreliable. Many are so primitive where the psyche is concerned that for them states of alcoholic inebriation are landmarks for judging mind-altering drugs. Alcohol and the entheogens are worlds apart. Their effects are different in kind. We must divorce alcohol from the entheogens: this is the first and great commandment. The entheogens, whose secrets the modem world is only now learning (chiefly from what I call 'Early Man' regardless of the chronological age) are a key to shamanism and the Mystery religions, a key that students have yet to evaluate at their full worth. In every case the use of these entheogens goes back as far as history, linguistics, and archæology carry us, and we must assume much further. Their use seems to be older than our oldest information. Not that the entheogens are needed to induce an ecstatic trance. Some people practicing shamanism do not know them. By dint of frenzied dancing, singing, shouting, and percussive music, chiefly drums, the shaman arrives at the desired state of ecstasy and finally falls down in a stupor, whereupon communication with the other world is established. The Hindus, perhaps inspired by a potent memory of their divine but inaccessible Soma, have evolved techniques - austerities, postures long maintained, physical exercises, mental concentration - that permit them to arrive at a state of 'contemplation' without the aid of plant hallucinogens. This state is of a different nature from the ecstasy we are discussing, and certainly its adepts rate its quality as superior, indeed as the ultimate in human achievement.

Botanists and anthropologists sometimes ask why we are discovering so many entheogens in use in the contemporary New World cultures, among Indian peoples of Mexico and southwards, as contrasted with their relative scarcity in Eurasia. Surely the answer lies in our being able to examine in the New World the many living cultures at the precise moment when they are entering the stage of their own proto-history from their prehistory. We catch these cultures when, so far as the entheogens go, they are still pure, thanks to the strange determination of our race through centuries not to trespass on this field - a boon certainly for us present day inquirers! In Eurasia we are dealing for the most part with cultures that emerged into history long ago, that have therefore left behind shamanism with its trappings, that have lost the secrets of their own herbalists of the remote past. Entheogens were always secret preparations in Greece and large parts of Eurasia, the secret spontaneously guarded by those privy to it. We must remember that the Indians of the New World have led our botanists by the hand to the entheogens. It would have been a lengthy, costly, perilous journey if we had had to rely on trial and error to arrive at those plants that, when properly handled, offer us psychotropic effects.

In his trance the shaman goes on a far journey - the place of the departed ancestors, or the nether world, or there where the gods dwell - and this wonderland is, I submit, precisely where the entheogens take us. They are a gateway to ecstasy. Ecstasy in itself is neither pleasant nor unpleasant. The bliss or panic into which it plunges you is incidental to ecstasy. When you are in a state of ecstasy, your very soul seems scooped out from your body and away it goes. Who controls its flight? Is it you, or your 'subconscious', or a 'higher power'? Perhaps it is pitch dark, yet you see and hear more clearly than you have ever seen or heard before. You are at l ast face to face with Ultimate Truth: this is the overwhelming impression (or illusion) that grips you. You may visit Hell, or the Elysian fields of Asphodel, or the Gobi desert, or Arctic wastes. You know awe, and bliss, and fear, even terror. Everyone experiences ecstasy in his own way, and never twice in the same way. Ecstasy is the very essence of shamanism. The neophyte from the great world associates the mushrooms primarily with visions, but for those who know the Indian language of the shaman the mushrooms 'speak' through the shaman. The mushroom is the Word: *es habla*, as Aurelio told me. The mushroom bestows on the *curandero* what the Greeks called *Logos*, the Aryans *Văc*, Vedic *kăvya*, 'poetic potency' as Louis Renou put it. The divine afflatus of poetry is the gift of the entheogen. The textual exegete skilled only in dissecting the cruces of the verses lying before him is of course indispensable and his shrewd observations should have our full attention, but unless gifted with *kăvya*, he does well to be cautious in discussing the higher reaches of Poetry. He dissects the verses but knows not ecstasy, which is the soul of the verses.

The shaman exercises his calling according to his lights. Every shaman puts on a different performance, and the extraordinary shaman is entitled to be called a virtuoso. His voice, his verses filled with traditional ('formulaic') phrases, his dancing, his percussive effects - these he works up in response to his little audience and in fulfillment of his genius, and there can be no doubt that sometimes the effect is telling. The reputation of a good shaman extends over a wide radius and some villages are famed for the shamans they produce, shamans with conviction, self-confidence, who *cantan recio*, 'sing stoutly', as they say. I believe villages exist in Mexico where there is such a strong tradition of shamanism that one may speak of a 'school' of shamanism associated with their names;[33] not of course an organized school but a tradition of shamanism permeating the village life and in which the villagers take quiet pride. While the shaman is not confined to any fixed liturgy, he is naturally a product of the cultural ambiance of his and the neighboring villages. He will be a prisoner of the conceptions of the universe and the beliefs that they possess, the practices that are habitual in the community. He may introduce personal variations into his performance, striking effects, but it is hardly possible for him to do violence to the framework of the world in which he has lived his life. He can only stretch that framework.

But what do we mean by 'stretching that framework'? In his ecstasy the shaman invokes in fervent verse and hymns the spirits that his neighbors know, gives utterance to the community's beliefs mythological and eschatological. When he is a man of intellectual power and moral prestige, will he not introduce grace notes into the common stock of those beliefs, variations and elaborations and deviations, within the confines that he senses are permissible and perhaps conforming to the inchoate notions already dimly felt by some in his gathering? Such deviations might take into account the heroic doings in war or hunting or when fishing on the high seas of the mighty men of his own generation, whom all have known, or natural catastrophes that have overtaken the village, or a migration to a new environment with strange and uncertain neighbors. These deviations will be accepted, and successive generations of shamans will bring innovations, which accounts for the fluidity of oral traditions among related peoples. For we speak of a world where there is no writing, where the corpus of cosmological and historical beliefs, the whole culture of the people and their vocabulary, lies in the minds and on the tongues of the living generation and nowhere else. Later, when the age of writing has arrived, an Herodotus comes along who puts down all the various recensions - 'some say this and some say that and yet others tell another story, but I think the truth is so-and-so'.[34] Surely the shaman preceded in time the itinerant bard, for the bard presupposes kings with their audience chambers and patronage and a degree of sophistication. The shaman knows only his neighbors among whom he has lived from the beginning. When possessed, he bears in his person the charisma of a village mediator with the spirits of the invisible world. How extraordinary that in this nuclear age so ancient a form of religious expression still survives, for a few more years, in the remote regions of the world!

Fly-agaric in the new world

In 1968 in my *Soma* I said that we should be thankful for the data we had assembled on the fly-agaric cult of Siberia but warned against exaggerating their importance. For a shamanic practice that had lasted we know not how many millennia our soundings reached back only three centuries, ripples on time's surface. Moreover those three centuries of cultural upheaval and chaos saw the end of the practice: it could be observed only when it was *in extremis*.

> Some of the observers [I wrote] were supercilious and none of them saw the implications of their observations. None of them seems to have been prepared in botany and none probed the questions that are compelling for us. The circumstances that brought them on the scene were at the same time bringing about the end of the beliefs and performances for which they were to be the sole witnesses. They were observing the fly-agaric cult only in its dying phase, when the

---

33. *Eg* San Lucas Zoquiapan, in the Sierra Mazateca.
34. This imprecision in all knowledge not tied to observations of nature (which by contrast are remarkably precise) is the dominant aspect of cultures in unlettered communities. Our earliest accounts - Homer, the Old Testament, the Rg Veda, the Kojiki, *etc* - bear witness to this. As for shamanism, in all the world's literatures there is surely no other shamanic performance that equals the mythic account in the Kojiki of Uzume's dance on an upturned rub before the cave where the sun-goddess has hidden herself. At the beginning of the eleventh century Lady Murasaki opens her *Tale of Gen ji* trailing the influences of the unlettered past of her people - 'some say this and some say that' - but she quickly hits her stride and thereafter she writes one of the most subtle and sophisticated of all novels of court life. Arthur Waley in the first and last of his footnotes, at the end of this opening chapter of the *Tale of Gen ji*, surprisingly fails to grasp the drama of this literary metamorphosis: he apologizes for his author and asks the reader to be indulgent! But she was only illustrating in her own gifted person how close is the unlettered mentality to the super-refined product of a cultivated society. In her person and her novel she was bridging the gap that separated the powerful pre-literate traditions of the Japanese and the sophisticated culture that they were drinking in from China.

> arean of its diffusion was being lopped away, when in some places the integrity of belief in it had bee undermined, and when the tribes themselves were mostly in a pitiful state of physical and psychological disarray. There is ample evidence that the ethnic movements, often gradual and more or less peaceful, in the inhospitable tundra and taiga of Siberia have been continuous, and we are far from unraveling them. In recent centuries the peoples practicing the fly-agaric cult have been living in areas to the north of where they were in their heyday, some of them on or close to the Arctic Ocean. They have been displaced from their former homes by Altaic tribes who do not, apparently, take the fly-agaric but who have absorbed into their shamanic practices the corpus of beliefs that go with the fly-agaric, beliefs that seem to accompany the ecology of the forest belt, especially the reverence for the birch. For the historian of human cultures it is a matter of regret that the impact of the modern world is inevitably brutal, bulldozer-like, in its disregard and contempt for the beliefs and ways of life of primitive peoples whom our industrial civilization wrenches from their traditions and tries, usually without success, to bring into step with our contemporary ideas. This holds true for the communist as well as the capitalist world.

When I wrote the foregoing paragraph about Siberian shamanism and the flyagaric, I did not anticipate the dénouement. True, almost twenty years ago Claude Lévi-Strauss had given me a lead in a Jesuit's letter to his brother written in the early seventeenth century, and in Lévi-Strauss's detailed review of *Soma* he expanded on other leads in the North American native cultures, but preoccupied as I was in a different direction and lacking the needed personal contact, those leads, though never forgotten, lay fallow. In 1975, through a combination of circumstances, I came to know, at first only by correspondence, a remarkable Ojibway herbalist and shaman, Keewaydinoquay,[35] living on a lovely island in Lake Michigan, the only resident on an island that had once belonged to her ancestors. There quickly unfolded before us an account of the fly-agaric cult that was breathtaking, not only for itself but for the fact that for centuries, millennia, the Ojibway, and in varying degrees the other peoples of the Algonkian nation, had looked to the fly-agaric for consultation about the most serious matters in their lives. The cultural trait that in Siberia we discerned dimly had been preserved for us, live and pure, as though in a time capsule, owing to the peculiar state of social relations between Whites and Algonkians during these last four hundred years.

And so, quite unexpectedly, we discover the cult of the fly-agaric in full panoply here in North America. No one knows when the Algonkians arrived here. The European settlers found them occupying a large part of North America, the Amerindian nation that is most widespread. Presumably they came across the Bering Strait, or else the land bridge that replaced the Strait during the successive Ice Ages. But if it should develop that they came from the north of Europe, in remote ages when the geography may have been different and stepping-stone islands permitted such transit, it would make no difference, for I think I have shown that the fly-agaric cult in former ages was circumpolar in extent, wherever the birch or appropriate conifers thrived.

As in Mexico, we owe the preservation of the cult into these modern times to the total lack of interest displayed by the White Man. It was an important and precious secret for the Ojibway, and they were not inclined to tell anyone about it who would sneer and scoff. How ironic it is that in Michigan and thereabouts, where the mycological faculties have considered themselves strong, the *miskwedo* (= *Amanita muscaria*) has played its age-old rôle among the Algonkians until now without so much as a nod from our mushroom men! (There need be no incompatibility between our mycologists and our ethnomycologists: witness Roger Heim.) Anthropologists and linguists have overlooked that rôle in spite of obvious clues in their standard sources and in spite of the widespread interest aroused by the anthology of Siberian source materials in my *SOMA: Divine Mushroom of Immortality*. Those in the Great Lakes area who take a professorial interest in the humane letters pass by on the other side when a poor Indian people not yet at home with the alphabet manifest their faith in a toadstool. Yet these same scholars will sit up straight at the mere mention of Eleusis or the Vedic Hymns, far removed though they are in time and space, or is it precisely because they are so removed?

Prof Bernard Lowy, mycologist of Louisiana State University, may well have uncovered exciting evidence in his ethnomycological investigations in Chiapas and the nearby Quiché-speaking area of Guatemala. There *Amanita muscaria* is common and well known but avoided. In Quiché, Dr Lowy tells us, it is called *kakuijá*, which carries the terrifying sense of *rayo* in Spanish, *foudre* in French, *parjanya* the thundergod in Sanskrit. Lightning in Spanish is commonly *relámpago* but this word is devoid of any aura of supernatural associations, free of mythological meaning. The Quiché speakers do not know why *A. muscaria* is the lightning-bolt and no longer think of the word's meaning when they use it. But *kakuijá* was the god of the lightning-bolt and this Quiché term is to be found in the *Popol Vuh*. How did this association of ideas, to which we are accustomed in Eurasia and among the Ojibway, arrive in the mountains of southern Mesoamerica? In Chichicastenango an alternative name for the *kakuljá* is *itzel ocox*, evil or diabolical mushroom. *A. muscaria* in Tuxtla Gutiérrez and San Cristóbal de las Casas is called *yuyo de rayo* when the native is speaking Spanish, again the mushroom of the lightning-bolt. For the Tzeltal-speakers in Zinacantan the fly-agaric is the *yuy chauk*, with the same meaning.

---

[35] Pronounced *Kee·way'dn·o'quay*

In folklore throughout Eurasia and Mesoamerica we are well acquainted with the tie that binds together the entheogenic mushroom and the lightning-bolt. Everywhere that tie is strong, but in Mesoamerica it generally belongs to the entheogenic Psilocybe and Stropharia genera: Dr Lowy has discovered one part of that area where the lightning-bolt impregnates the soft earth with the 'toad-mushroom'. Does this word *kakuljá* come from a time when the ancestors of the Quiché knew the secret of *A. muscaria* and used it? Did they abandon it because, long ago, they found the Psilocybe species preferable? Or because the friars in post-Conquest times drove it out?

New perspectives in ethnomycology are beckoning to us.

39. Garibay K., Angel María. [4] Ed *Poesía Náhuatl* in 3 Vols: Vol 1, 1964; Vol 2, 1965; Vol 3, 1968. UNAM, México D F Father Garibay denies that the sacred mushrooms figure in Nahuatl poetry, even when they are openly cited, saying that the reference is a poetic metaphor. See note in Vol 2, poem 28, p xcv. We mention in our text a lyric that Father Garibay conjectures was composed by a captive awaiting sacrifice: this is in Vol 2, p 122; note on p cxxviii to poem 30.
40. Garibay K., Angel María. [5] Ed *Historia de las Indias de la Nueva España* by Diego Durán. Vols 1, 2. Porrúa, México D F 1967
    Father Garibay in his Introductory Notes to Vol 1, p xv, says: 'Without straining the evidence in the least, I think that the implications lead us to view as probable, and even almost certain, a Jewish origin for Diego Durán. It is worthy of note that the most devoted investigators of the previous culture - Durán and Sahagún - are almost certainly of Jewish lineage.' [Translation mine: R.G.W.]

100. Safford, W. E. [2] 'An Aztec narcotic'. *Journal of Heredity*, Vol 6, July 1915, pp 291-311
    This economic botanist, renowned in his day, in a full-dress study here advanced the thesis that the hallucinogenic mushrooms had never existed, and that early Spanish padres had confused peyote with fungi. R.G.W.
101. Safford, W. E. [3] 'Peyotl, the narcotic mescal button of the Indians.' *Journal of American Medical Association*, Vol 77:16, Oct 15, 1921, pp 1278-1279
    This article, published shortly before Safford's death, shows that he still persisted in his mistaken belief. R.G.W.
102. Sahagún, Fray Bernardino de. *Historia General de las Casas de Nueva España*
    1. Spanish text of the Florentine Codex. Edited in 4 Vols by Angel María Garibay K. Porrúa, México D F, 1956. Hallucinogenic mushrooms are cited in Sahagún's Spanish text and in the Flor Codex in the following places:
       (a) Bk IX, Chap viii; Flor Codex, fol 31r-31v
       (b) Bk X, Chap xxiv Par 16-17; Chap xxix, Par 34; Flor Codex, fol 122v
       (c) Bk XI, Chap vii, par 70, 74; Flor Codex, fol 129v-131r; illus No 516
    2. Nahuatl text of Flor Codex as translated into English by Arthur J. O. Anderson and Charles Dibble, University of New Mexico and of Utah, in 13 parts. Hallucinogenic mushrooms are cited in the following places:
       (a) Bk 9 pp 38-9

(b) Bk 10 pp 12, 20, 37, 49, 55, 88, 173
(c) Bk 11 pp 120 (under Teonacaztli), 129, 130; illus No 516

(The description of the Teonacaztli tree likens inebriation from its fruit to mushroom inebriation. In the Spanish texts on this tree - Bk 11 6:49 and 7:294 - the mushroom analogy is omitted.)

Sahagún is the monumental figure in Aztec historiography, an inexhaustible quarry for research. If I have proved my case for the metaphorical meaning of *flowers* in the language of the Princes and other leaders of Aztec society, we should comb the Sahagún material, in Nahuatl and Spanish, for the words *octli* and *xochitl*, 'flores' and 'rosas', to see where they signify the superior entheogens. For instance, in Bk 6 14-45 of the Spanish text the newly elected Prince is delivering the expected allocution to his people in which he exhorts them to lead virtuous lives and to emulate the past heroes who have died gloriously in war, heroes who (he says) are now living at ease in a world of delights, where they *chupan la suavidad de las flores del cielo*, 'sip the softness of the heavenly flowers'. Here indeed are our mushrooms or other superior hallucinogens. When we look at the Nahuatl text (Dibble & Anderson, Bk 6 p 74) we see that it says only 'who sip forever', '*flowers*' being understood. Dibble & Anderson in their translation from the Nahuatl interpolate them: 'who sip (the flower nectar) forever'. They must have looked to Sahagún's translation to arrive at the sense of 'sipping' the *flores del cielo*. In this key passage does not Sahagún give himself away? When his Nahuatl informant said 'sipping forever', Sahagún knew (or learned at that moment) the idiom for 'sipping [heavenly flowers] forever'. But certainly Sahagún with his powerful intellect and his empathy with the Indians, must have learned from his informants from early on the metaphorical meaning of '*flowers*'. Conforming to the practice of the other clergy, throughout his great work he played down drastically the rôle of the hallucinogens. R.G.W.

Ethnomycological bibliography of R. G. and V. P. Wasson. July 1979

Books

1. Wasson, Valentina Pavlovna, and R. Gordon Wasson. *Mushrooms Russia and History*, 2 vol. With 85 plates, of which 26 are watercolors by Henri Fabre, reproduced by Daniel Jacomet, Paris, by the *pochoir* process. Pantheon Books, New York, 1957. Edition of 512 copies.
2. Wasson, R. Gordon. *SOMA: Divine Mushroom of Immortality*. New York: Harcourt, Brace & World, Inc. The Hague: Mouton, 1968 (1969). *De luxe* edition 680 copies; hardcover edition, paperback printings. Ethnomycological Studies No 1.
3. Wasson, R. Gordon, George and Florence Cowan, and Willard Rhodes. Photos by Allan Richardson. *María Sabina and Her Mazatec Mushroom Velada*. Harcourt Brace Jovanovich, New York and London, A Helen and Kurt Wolff Book, 1974. Complete text of *Velada* in Mazatec, translated into Spanish and English. Musical score by Willard Rhodes. Commentary by Wasson, the Cowans, and Rhodes. Ethnomycological Studies No 3.
4. Wasson, R. Gordon, Albert Hofmann, and Carl A. P. Ruck. *The Road to Eleusis: Unveiling the Secret of the Mysteries*, with a new translation of the *Homeric Hymn to Demeter* by Danny Staples. Harcourt Brace Jovanovich, New York and London. A Helen and Kurt Wolff Book. May 30, 1978. Ethnomycological Studies No 4.

(In collaboration with Roger Heim):

5. Heim, Roger, et R. Gordon Wasson. *Les Champignons hallucinogènes du Mexique*. With 37 full page plates of which 17 are in color, 83 illustrations in the text of which 14 are in color: and three maps. Edition du Musèum National d'Histoire Naturelle, Paris, Serie 7, Tome VI. 1958 (1959). Wasson is the author of the first three chapters, pp 15-122.
6. Heim, Roger, with the collaboration of Roger Cailleux, R. Gordon Wasson, and P. Thévenard. *Nouvelles Investigations sur les Champignons Hallucinogènes*. With 12 full page plates of which 5 are reproduced by *pochoir* process and one in four-color, 34 illustrations in the text of which 5 in color, and one map. Edition du Muséum National d'Histoire Naturelle, Paris, 1967.

Articles

1. Wasson, R. Gordon. 'Lightning-bolt and Mushrooms: An Essay in Early Cultural Exploration.' Festschrift: *For Roman Jakobson*, Mouton, The Hague, 1956, pp 605-612. Republished with illustrations in Dutch in *Antiquity and Survival* III: (1960) 1.
2. Wasson, R. Gordon. 'The Hallucinogenic Mushrooms of Mexico: An Adventure in Ethnomycological Exploration.' *Transactions* of The New York Academy of Sciences. Series II, Vol 21, No 4, pp 325-339. February 1957.
3. Wasson, R. Gordon. 'Seeking the Magic Mushroom.' With water colors by Roger Heim and photographs by Allan Richardson. *Life* magazine, N. Y., May 13, 1957. (International edition, June 10; 'En Busca de los Hongos Mágicos', *Life en Español*, June 3.)

For your special library on sacred drugs... two additional volumes of extraordinary interest!

PLANTS OF THE GODS Origins of Hallucinogenic Use

By Richard Evans Schultes and Albert Hofmann
With 380 illustrations (110 in full color)

Mushrooms . . . Hashish . . . Peyote . . . Ergot . . . LSD . . . Datura. Hallucinogens, yes. But what else do you know about them and some 80 others? A botanist and a chemist, both renowned authorities, bring you a fascinating study of psychoactive flora — where you find the plants, what's in them, how they're prepared and ingested, how they're used in religious rites, medical practice, meditation, and art and poetry. And what their effects are. A colorfully illustrated lexicon of 91 plants and their properties gives you facts you'd have to consult many medical journals to find, while the rest of this beautiful volume unfolds the story of the peoples who use sacred plants today as part of their cultural heritage. *192 pp., outsize format, hardcover.*

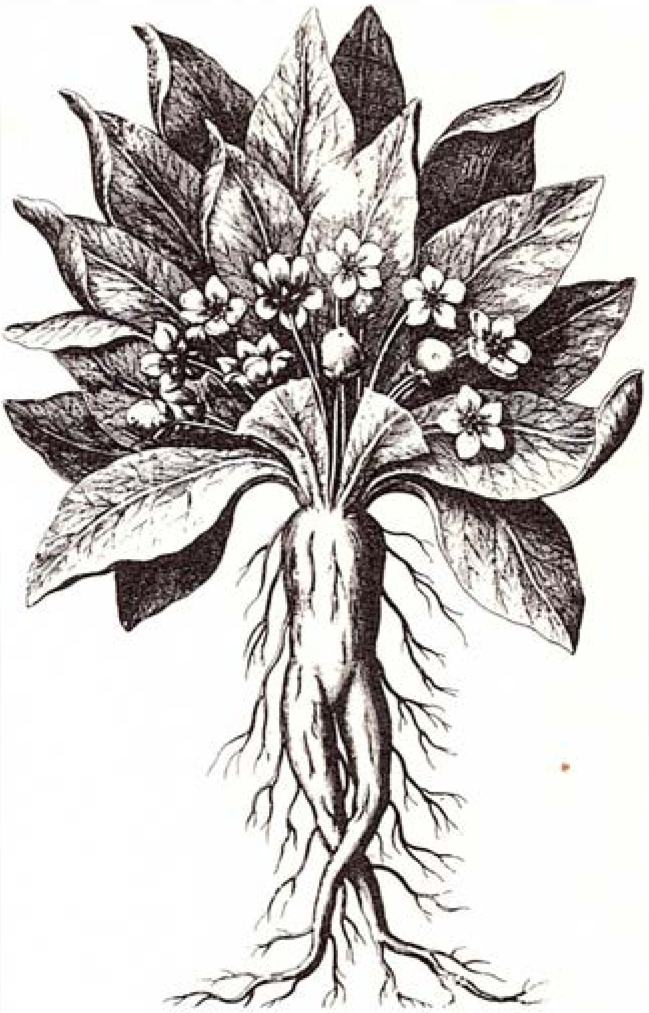
LSD: My Problem Child

By Albert Hofmann
192 pp., hardcover

The world-famous chemist and father of LSD recounts the intriguing inside story of how he came to synthesize LSD and how he now views the significance and implications of his important discovery. With complete candor he relates his encounters with such gurus as Huxley, Leary, and Wasson. He advances his own mystical philosophy in which he asserts that hallucinogens do indeed constitute cracks in the edifice of materialism. His book is, in a real sense, the story of the ''birth of the Psychedelic Age.''

McGraw-Hill Book Company

Mc
Graw
Hill



R. GORDON WASSON the preeminent authority on the use of psychoactive mushrooms in the history of such various culture areas as Siberia, India, Greece, and North and Central America, is Honorary Research Fellow with Harvard University's Botanical Museum and Honorary Research Associate with the New York Botanical Garden. The creator and pioneer of the science of ethnomycology, he has written numerous highly lauded books on hallucinogenic mushrooms, including *SOMA: Divine Mushroom of Immortality* and the recent *THE ROAD TO ELEUSIS*.

From the beginning, Wasson's interest in the entheogenic ("God-within-us") mushroom has lain solely in their role in Early Man's religious life. During decades of observation and study, Wasson—with his wife—surmised that mushroom worship prevailed among our remote ancestors in most of Eurasia and the Americas. Then they found proof that mycolatry ("The worship of a mushroom") had indeed also prevailed among peoples on the Arctic Ocean borders reaching all the way to the Bering Strait. And not only there but, as they discovered in the 1950s, among the peoples of Mesoamerica—an area that includes Nicaragua, Guatemala, Western Honduras, El Salvador, Belize, and Mexico east, west, and just north of Mexico City.

According to Dr. Wasson, the psychoactive mushrooms have been overlooked by scholars. He finds them in pre-Conquest mythology and poetry, in pre-Conquest sculpture and mural painting, even in some post-Conquest ecclesiastical art.

McGRAW-HILL BOOK COMPANY
Serving the Need for Knowledge
1221 Avenue of the Americas
New York, N.Y. 10020

". . . A CONSIDERABLE EVENT!"

For R. Gordon Wasson's many thousands of devoted readers and students both inside and outside today's community of specialists, this new book by "the acknowledged ranking ethnomycologist," is indeed, as Duke University's renowned Weston La Barre declares, *"a considerable event!"*

Your enthrallment begins with the book's opening description of the author's all-night vigil at a shamanic mushroom ceremony—the *velada*—in Huautla, Mexico. Against this awe-inspiring setting, you embark on a revolutionary investigation and analysis of the meaning and use of the divine hallucinogenic mushroom, *Psilocybe mexicana,* and its relevance to the cultures and peoples of Mesoamerica from pre-Columbian times to the present.

In its pages you will take part in the sacred ritual, become familiar with its rules and taboos, and witness, as if you were actually present, both the contemporary and historical impact of the sacred mushroom. You will actually *experience* its deep significance to users for healing, meditation, divination, and religious worship.

Astonishing photographs and drawings accompany Wasson's deep and sensitive penetration into the living and past cultures of Southern Mexico, and the role of the divine plant in the natives' religion, where the Indian happily weds it to Christianity.

A unique work, the book offers a vital key to our understanding not only of pre-Columbian art and literature before it was touched by European and Asian influences but also of the importance of the mushroom throughout the area today. It is the high culmination of Wasson's rich experiences, discoveries, and insights gleaned from a lifetime of voyages into the deepest territories of the hallucinogenic worlds, both past and present. In it he has distilled the sum total of all that he has learned and all he now believes to be the significance of the way people have used sacred drugs—as an element of life, of daily human activity, and as a source of constant and special spiritual strength.

THE WONDROUS MUSHROOM will stand as a supreme contribution to anthropological, pharmacological, and art research. Above all, it will remain a human experience not to be missed.

Mushroom Ritual versus Christianity

by

Eunice Pike and Florence Cowan

original source: http://www.mushroomjohn.org/pikeandcowan1.htm

Miss Eunice V. Pike and Mrs. Florence Cowan are members of the Wycliffe Bible Translators, working among the Mazateco Indian group of Oaxaca, Mexico. During their years of service in this field they have participated in the translation of the New Testament in Mazateco, which is currently in the process of publication.

How can one effectively present the message of divine revelation to a people who already have, according to their belief, a means whereby anyone who so desires may get messages directly from the supernatural world via a more spectacular and immediately satisfying way than Christianity has to offer? The Mazateco Indians equate the hallucinogenic mushroom with Jesus Christ himself, believing that when Jesus lived on earth he spat on the ground and his saliva sprang up as the mushroom. Through it as his mouthpiece, he speaks to them in the hallucinations which its chemical content induces. Christian hymns taught by the missionary are sometimes believed to be inspired by the mushroom and are probably sung to it by its devotes. Taboos applicable to mushroom eating are transferred to the Bible and result in fear of reading it. The partaking of the divine mushroom poses potential problems in relation to the Christian concept of the Lord's Supper. The use of the mushroom in southern Mexico in the quest of visions and supernatural revelations would appear to have many points in common with the use of peyote by the Indians of northern Mexico and the U.S.A., where there has been extensive syncretism of peyote ritual and Christian forms. PRACTICAL ANTHROPOLOGY would welcome further contributions on the problems of communicating the Christian message in this type of context. It is a subject that still needs much careful and prayerful study.

Some of the Indian groups of southern Mexico make ritual use of certain species of mushroom which have hallucinatory powers. The ceremonies are performed by a curandera or shaman but with the participation of other persons. Pagan and Catholic traits blend in the ritual, which is carried out in the presence of Catholic images. This use of the mushroom is centuries old, having been described by the early Spanish writers. The present article is based on the ritual as it is observed today among the Mazateco Indians of the State of Oaxaca. Our information for the most part comes from four sources: from the people who participate in the ceremonies, from shaman women who have become our friends, from overhearing the ceremony as it took place in a house next door to us, and from tape recordings of two all-night sessions which were made by R. G. Wasson and which he permitted us to hear[1].

[1] For specific details see V. P. and R. G. Wasson, *Mushrooms, Russia and History*. New York: Pantheon Books, 1957. A popular but valuable presentation of the mushroom ritual appears as a feature article by R. G. Wasson, "Seeking the Magic Mushroom," in *Life*, May 13, 1957, and *Life International*, June 10, 1957. See also Valentina P. Wasson, "I Ate the Sacred Mushroom," in *This Week Magazine*. May 19, 1957. For a later news report on the medicinal qualities of the hallucinogenic mushroom, see "Mushroom Madness," in Time. June 16, 1958.

Deceptive Mixtures

From all four of these sources we learn that the old tribal beliefs and Christian ideas and terminology have become mixed. One minute the shaman (a woman in both ceremonies which were recorded) would chant that she had the heart of Christ or the heart of the Virgin Mary; the next minute she was chanting that she was a snake woman, a moon woman, a bird woman. At both sessions she sang the Lord's prayer as it is sung in the Catholic church in the town of Huautla; but the next moment she was chanting about being a southern cross woman, or talking about a tiger eating someone's soul.

Many kinds of mushrooms grow in the Mazateco area, but only certain ones are used in the ceremony and only these will be discussed in this paper. Some informants say that the mushroom grows wherever a drop of Christ's saliva fell and that for that reason when the mushroom speaks it is Christ himself speaking. Other informants say that the mushroom grows wherever a drop of Christ's blood fell, and that for that reason the Huautla region has living land - land where the mushroom does not grow is dead.

The most common reason for eating the mushroom is in behalf of someone who is ill. One informant said, "Jesus Christ himself gave us the mushroom because we are poor people and have no doctors or medicine to help us." At other times the mushroom is used for divining such things as who stole a certain horse, who killed a certain man, whether or not a sick person will die, or the welfare of a person who is away from home. At the ceremony anyone present may eat the mushroom, but the shaman eats several times as many as the others. All see visions (beautiful colored moving pictures, they say), but the shaman chants and sings while the others lie quietly on straw mats. They may speak encouraging words to the shaman or make comments to one another. Somehow when the session is over, they have the impression that 'Jesus' has given them the answers. They know that the sick person will get better or die, that they must get the help of the doctor, call in the witch doctor, or look for certain herbs. They know that their relative int the faraway city is well or in trouble.

However, we have conflicting reports on how 'Jesus' goes about telling them these things. Our information differs sharply depending on its source. The patients, or people who hire the shaman, say, "Jesus said that my son would get better," or "Jesus told me to stop drinking liquor," or "The little mushroom said so." The patients never say, "The shaman said that Jesus said. ..." But one of our shaman friends insists that 'Jesus' doesn't 'tell' her anything. She insists that he never actually speaks to her. She 'sees' the sick boy well, or she 'sees' a tiger eating his soul. Her visions are like movies or television and she just talks about what she sees going on.

In the tape recording of the two ceremonies we were not able to pick any place where a supernatural being talked in first person giving a message. It was just the shaman singing about what a wonderful person she herself was. However, a mother told one of us that the mushroom had told her that her daughter would die and then added, "But don't be afraid, I'll take her soul to be with me." W have had hints that 'Jesus' talks directly to the sick person, or to the relatives by means of the mushrooms that they themselves have eaten. All our sources, however, agree that somehow those asking for guidance receive it, and that 'Jesus' is the one who gives it to them.

Attempts at Separation

We find that the deep-seated belief in the mushroom frequently causes the Mazatecos to misunderstand our witness for Christ. We must ever be alert to their way of thinking so that we may chose unambiguous words. Examples of some of the problems follow.

1. At least twice when describing heaven as a beautiful place, a place where there are no tears, etc., Eunice Pike has been asked, "Have you seen it?" She answered, "No," and at that time thought the question very queer - didn't the person know that only the dead have seen heave? Later she realized that a high percentage of Mazatecos claim to have seen heaven - the mushroom gives them moving pictures of it. Now she tells people, "The Book which tells us about God says that heaven. ..."

2. A shaman is respected and called a 'wise man' by the Mazatecos. One time a shaman stood listening to one of the authors witness about Christ. The expression on his face was one of sympathy and understanding. After a bit he spoke up, "I, too, am a wise man." The missionary didn't recover fast enough to tell him that she differed from him in that the things she taught were only those things which are in accord with God's written Word.

3. One time when one of the writers was objecting to the use of the mushroom she was told, "But what else could I do? I needed to know God's will and I don't know how to read."

4. One cloudy day the missionary was sitting at the local airstrip hoping that the plane would arrive. A number of Mazatecos were also waiting. To redeem the time she sang a hymn, planning to use it as a starting point for witnessing. The hymn she happened to choose was a new one that no Mazateco knew yet; in fact, she had translated it just the day before. As she sang she heard two of the women talking. "Isn't that beautiful! How

lovely! It's just like the mushroom." They had not been talking to her, but she couldn't keep out of that conversation. "No, it's not like the mushroom. This is different." The women would not listen. Emphatically they broke in to say, "We mean, wasn't it gracious of the mushroom to teach you that song!"

Many people have learned a number of the hymns in Mazateco, since at least five hundred phonograph records with hymns and a gospel message have been sold in the area. We now suspect that some of the hymns have been sung to the mushroom by the shaman. In fact, one Christian Mazateco warned one of the authors against teaching any hymns to her shaman friend. "She may sing them to the mushroom if you do!" All this poses many problems. Should we limit the sale of records to Christians only? But the wonderful thing about a record is that it can go where there are no Christians and no missionary. Should we teach hymns only to Christians? But singing a hymn is one of the easiest ways to start a conversation about Christ. We have gone on teaching the hymns, but now we are alert, ready to point out that a hymn is in accord with the Scriptures, whereas many of the shaman's chants are contrary to them.

5. There is one taboo that most people consider very necessary to observe when eating the mushroom. That is, they have to be ceremonially 'good' or 'clean'. Specifically, they must refrain from sexual intercourse for four or five days both before and after eating the mushroom. One of our shaman friends said that she had started eating the mushroom in behalf of others when she was twenty years old, but that she had stopped completely when she married. After her husband died she took up that work again. Then she married a second time, and again she stopped. Widowed the second time, she took up the work of shaman again.

This taboo which is imposed in connection with eating the mushroom has, it seems, been a direct source of difficulty in the distribution of the Scriptures. We tend to call the Scriptures "God's Word". The Mazatecos have considered the mushroom a means of getting a message from God, and hence the two things tend to get grouped in the same category. If such a taboo applies to the one, in the minds of at least some Mazatecos it applies to the other.

One young man of marrying age had been reading the Scriptures and enjoying them. Then one day he told us that he was thinking of getting married, and he wondered whether he could go on reading the Scriptures, or if he must stop once he was married. A leader in one village, a married man, seemed hungry for the gospel, listened eagerly when taught, asked pertinent questions, and seemed to accept the Lord and prayed for forgiveness of sin and for the Lord to bless his wife and children. But although well off financially he refused to buy the Scriptures and never read them for himself. When urged, he objected with, "People say that we will go crazy if we read God's Word." It was at least a year later that it dawned on us that the same reason is given for observing the taboos when eating the mushroom. One of our neighbors went crazy and we were told in a whisper that is was because he ate the mushroom when not 'clean'.

These and other incidents make us suspect that the taboo is so interpreted as to make people in general afraid to read the Scripture. Parents are afraid that their children will die. We are struggling with the problem and perhaps we are making progress. When selling Scripture in the market, we no longer use the term "God's Word"; rather we say, "This book teaches us about God."

Also we have made up a wedding song which gives advice to the Mazateco couple. (Old folks are supposed to give advice to a Mazateco couple.) The first verse tells of a couple getting married, and urges that they take the Jesus road. The husband is urged to love his wife. The wife is urged to respect her husband. Then in the second stanza they are urged to read the Scriptures. In the third stanza they are told to teach their children the Jesus way. That song is a good jumping off point to urge that the couple read and pray together.

6. It would appear that the eating of the mushroom has features in common with the Christian Eucharist, which are a potential source of confusion. During the mushroom ceremony the people all nibble on the mushroom at the same time. They make a kind of unit listening to the shaman sing and seeing visions together. In his description Wasson applied the word "agape" to the ceremony, and we have been asked (by outsiders) if the Mazatecos confuse it with the Lord's Supper. Does the eating of the divine mushroom have for the Mazateco a psychological value comparable to that which the Eucharist has for the Christian? What teaching must accompany the introduction of the Lord's Supper to the Mazatecos to prevent the Christians among them from seeking the same experience from the bread and wine that they have formerly gotten from the mushroom - and being disappointed? All this needs careful study and development in the local church context. We can see

possibilities of confusion. One Mazateco said that the mushroom must not be cooked because it is considered as a living person. However, since there is still no organized Mazateco church there has as yet been no celebration of the Lord's Supper, and therefore as of this date we know of no confusion. We have hopes that there will be none, for at least a handful of individuals have not stumbled when they received private instruction.

Supplying the Need now Filled by the Mushroom

Medicine has given at least some Christians the courage to reject the mushroom. When a non-Christian sister-in-law says, "You are killing your husband! Why don't you call the wise man?" (meaning that, if the wife does not call a shaman when her husband is sick, then she is the same as a murderer), the Christian can save face by answering, "I'm using medicine instead." That not only keeps the relatives from pressing so hard, but the medicine sometimes cures the patient.

The Mazatecos have occasions when they desire some special knowledge for which they usually turn to the mushroom. Sometimes this desire has been met by citing the admonition in James 1:5. We point out that God has promised to give us wisdom if we ask him. Once, when a Mazateco Christian asked, "How does a Jesus' follower go about finding a horse?, we prayed with him, asking for wisdom and guidance, and then suggested that he go out and hunt. He found the horse!

Perhaps part of the reason for using the mushroom is to have a party-like thing, or some special attention for the sick relative. If that be the case, then the need might be filled by public prayer for the sick one during the Christian service.

Surpassing the Mushroom

The shaman sings that the mushroom says she is clean, good, victorious. It calls her a humming bird, the moon, the morning star, the southern cross. She is an interpreter, a woman by whom others live, the law, medicine, justice. The mushroom says that she is the child god, a spirit, a saint, a creator, the heart of Christ, the heart of the Virgin Mary. She is light, speech, thought. But in spite of the pretty words the shaman is afraid. Even as she sings she fears her earthly enemies. She is afraid of the harm that may be done to her or her family by witchcraft (i.e. by a type of witchcraft that is completely apart from the mushroom). We had noticed in listening to the tapes that at times the shaman was weeping as she chanted. Upon being questioned, she explained to us that she was weeping because she was remembering that one of her sons had been murdered and she was concerned for the one that was left.

The mushroom often breeds fear. The visions may show the shaman that the patient is dying of 'fear sickness' with no suggestion of how to cure him. The relatives accept the diagnosis and prepare for the funeral while they wonder what it was that frightened him. In contrast, our Lord said (John 14:27), "Peace I leave with you, my peace I give unto you; not as the world giveth, give I unto you." In practice we have found this passage of Scripture to be true; many of the Mazateco Christians, with turmoil around them, have come to have hope and an inner peace - a peace that comes from knowing that they have a Savior, and Someone who loves them.

By contrast, in neither of the two mushroom tapes could we discover help for someone who knows that he is a sinner and needs salvation. The shaman sings of the greatness that she is said to have, but that greatness is of no real help to her; she is as bad off as any of the other 90,000 Mazatecos. Our Lord, however, can take a down-and-out repentant sinner and clean him up until he can bear the fruits of the Spirit.

The ethical values mentioned in the mushroom ceremony are in keeping with the values generally recognized in Indian cultures, but they fall far short of the ethics of Christianity. In the long list of virtues that the shaman claims for herself during the ceremony, there is no love, joy, peace, kindness, grace, or gentleness - none of the qualities that we recognize as fruits of the Spirit. These, however, are things that mark one who has become a Christian in the Mazateco society: love for family and for fellow Christians, joy in spite of hardships, peace in the midst of village wars. "By this shall all men know that ye are my disciples, if ye have love one to another" (John 13:35).

Conclusion

Some Mazateco believers, chiefly new Christians, have continued to use the mushroom for a while. Arguments against it have accomplished very little. The thing that has helped is study of the Scriptures - any and all parts of them - until the person concerned comes to understand God's idea of sin, his love and plan for the sinner, and something of God's greatness. That seldom happens after the study of a few brief passages; it seems to take a considerable amount before a person's eyes are opened.

The entheomycological origin of Egyptian crowns and the esoteric underpinnings of Egyptian religion

Abstract

In this paper, I theorize that the Egyptian White and Triple Crowns were originally primordia of the entheogenic *Psilocybe* (*Stropharia*) *cubensis*, which an Egyptian tale known as *Cheops and the Magicians* allegorically explained grew on barley, and that Osiris was the God of spiritual rebirth because he personified this and other entheogenic mushrooms. I go on to theorize that the plant known commonly as the Eye of Horus, which the Egyptians included in cakes and ales designed to spiritually rebirth the living and the dead, was an entheogenic mushroom cap entirely analogous, if not identical, to Soma. Finally, I explain why so many scholars failed to discern these identities and relationships for so long.

Keywords: Egypt; Ethnobotany; Agaricales; *Amanita muscaria*; Psilocybine; History

1. Introduction

Ethnopharmacology was derived from the Greek words *ethnos* for people and pharmacology for the characteristics, properties, and effects of a drug. Accordingly, *ethnopharmacology* is, by definition, as much a social science as it is an experimental science, in that it is concerned with the way people used and continue to use drugs derived from plants.

Ethnopharmacologists must therefore often rely as much on the methods and materials historians, archaeologists, and various other specialists use to study a culture as they do on the more rigid methods and materials clinical and experimental pharmacologists use to study a culture's drugs. In fact, when the drugs in question are those of an ancient culture, ethnopharmacologists must often rely to a far greater extent, and in some cases solely, on that culture's literature and art, than on scientifically derived data.

This is particularly true if the drugs in question were used in an ancient culture's religious rituals, for such rituals were typically performed covertly, as the following passage of the Egyptian *Book of The Dead* (Budge, 1969a,b) makes clear:

> And you shall perform these ceremonies secretly in the Tuat-chamber of the tomb, for they are mysteries of the Tuat, and they are symbolic of the things which are done in Khert-Neter... Let no stranger anywhere have knowledge of it. Do not speak about it to any man. Do not repeat it. Let no [other] eye see it. Let no [other] ear hear it. Let no one see it except [thyself] and him who taught [it to thee]. Let not the multitude [know of it] except thyself and the beloved friend of thy heart.

Moreover, this is particularly true when the drugs in question were used in the ancient Near East, for paleobotanical evidence from this region is remarkably rare (Merlin, 2003).

Nevertheless, the literature and art of many ancient Near Eastern cultures have shed a great deal of light on the way members of these cultures used drugs recreationally, medicinally, and religiously. For example, La droga en el Antiguo Egipto noted pictures of the following psychoactive plants on the tomb walls of Egyptian Pharaohs and their bureaucrats: (1) the lotuses *Nymphaea alba* and *Nymphaea caerulea*, which contain the psychoactive alkoloid apomorphine; (2) *Lactuca verosa*, a substitute for opium with mild hypnotic effects; (3) the poppy *Papaver somniferum*, from which opium is, of course, extracted.

It is therefore not surprising that ancient Egyptian priests were designated by the Egyptian word *sem* for plants, or that these priests contemporaneously served as physicians - for the Egyptians, like all ancient peoples, believed that health and disease could be attributed to the actions of Gods. However, unlike the modern, Western medical practice of prescribing drugs for an afflicted person to take, an ancient Egyptian physician-priest would often himself take a drug that would presumably allow him to commune with the Gods on behalf of the afflicted person, and he would often administer drugs to spiritually rebirth, or even physically resurrect, the dead. Hence, Egyptian medicine and religion were inseparable.

In fact, since Egyptian physician-priests apparently had a considerable amount of expertise in the medico-religious use of botanicals, especially in the pursuit of immortality, it is not surprising that Medieval alchemists, whose occult religious pursuit of immortality ended up fathering pharmacology, were extremely interested in Egyptian religion, to the extent that our word *chemical* can ultimately be traced back through *alchemy* to the Greek word *Khemia* for Egypt. Heinrich (2002) presented a great deal of iconographic and textual evidence supporting his theory that the *alchemical* pursuit of immortality originally revolved particularly around the covert ingestion and investigation of the *Amanita muscaria*, and possibly the *Psilocybe cubensis*, just as Wasson (1968) presented a great deal of evidence that the ancient Hindu pursuit of immortality originally revolved around the covert ingestion of the *Amanita muscaria*, and later perhaps the *Psilocybe cubensis*, ostensibly as the deity Soma. Similarly, Graves (1960) and Ruck *et al*. (2001) presented a great deal of evidence supporting their theories that ancient Greek religion once revolved around the ingestion of the *Amanita muscaria* and, perhaps ergot, just as Wilson (2001) presented a great deal of evidence supporting his theory that Celts ingested the *Amanita muscaria* in their religious practices.

Indeed, Puharich (1959), a U.S. Army psychiatrist working at a chemical and biological warfare center in Maryland, claimed, on seemingly spurious grounds, that the ancient Egyptians used the *Amanita muscaria* to relieve pain and induce out-of-body experiences, and the U.S. government considered these claims important enough to spend many years investigating them.

It was subsequently learned that the ibotenic acid in the *Amanita muscaria* is an analogue of glutamic acid, which acts on nerve endings to effect analgesia, and that drying converts the ibotenic acid into muscimol, an analogue of GABA, which can indeed relieve pain. This paper examines the hypothesis that the ancient Egyptian practice of communing with their Gods, particularly in the pursuit of immortality, may have once revolved around the covert ingestion of the *Amanita muscaria* and *Psilocybe cubensis* in the hope that the positive results reported will be deemed interesting enough to prompt other studies of the subject.

2. Materials and methods

A variety of the ancient Egyptian texts and artworks are examined in view of the hypothesis that many Egyptian symbols were originally designed to represent entheogenic mushrooms, and Wasson's theory that a significant portion of the Rg Veda esoterically refers to *Amanita muscaria* and, perhaps, *Psilocybe cubensis* ingestion. As Merlin (2003) noted in his study of the ancient use of psychoactive plants, all such evidence is subject to interpretation and reconstruction, and disagreement may arise concerning the represented species. However, a lack or scarcity of evidence, in this case paleobotanical, does not necessarily mean that the depicted plants were absent.

3. Results

Fig. 1 shows the striking resemblance one typical and two anomalous Egyptian White Crowns, or *hedjeti* (Fig. 1B-D), bear to the pin-stage primordium of the *Psilocybe* (*Stropharia*) *cubensis* (Fig. 1A). This mushroom is considered an entheogen (Gk. *entheos* 'filled with God' + *gen* - 'to make') (Ruck, 1979), because the psychotropic chemicals, psilocybine and psilocin, it contains are known for leading people to believe, among other things, that they are divine and immortal.

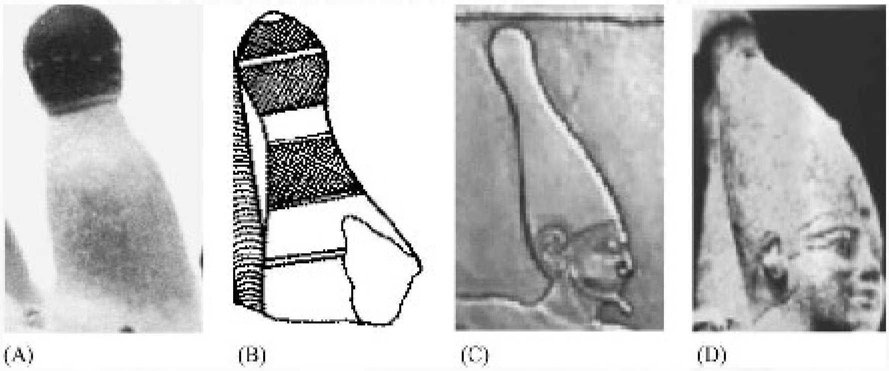

Fig. 1. (A) Pin-stage primordium of *Psilocybe cubensis* strikingly resembling (B) anomalous White Crown on an 11th Dynasty tomb wall at Deir-el-Bahari (Naville, 1910; Abubakr, 1937); (C) King Narmer's White Crown; (D) Pharaoh Sesostris I's anomalous White Crown (Evers, 1929).

Accordingly, there are grounds for believing that the Pharaohs - who also served as high *sem*, or herbal, priests - were essentially shamanic herbalists, whose well-documented belief in their own divinity and immortality was induced by *Psilocybe cubensis* ingestion, and that these monarchs then paid homage to the *Psilocybe cubensis*, first by wearing various stages of it on their heads and, later, by wearing representations of those stages as crowns.

This identification can also explain why, for instance, an Egyptian artist cross-hatched areas of the White Crown on an 11th Dynasty tomb wall at Deir-el-Bahari (Naville, 1910; Abubakr, 1937) (Fig. 1B) in a way that caused its top, or handle, to correspond precisely to the head and necklace of a *Psilocybe cubensis* primordium (Fig. 1A), while an Egyptian sculptor flattened the lower part of the bulb, or handle, of pharaoh Sesostris I's White Crown (Fig. 1D) in a way that caused it to strikingly resemble a *Psilocybe* cap emerging from its primordium. Hence, Abubakr (1937), in his extensive work on Egyptian crowns, was prompted to describe Sesostris I's crown as "pilzartige Form" (mushroom-shaped), though Abubakr did not realize just how appropriate his characterization of this crown was or the reason for the crown's heretofore enigmatic shape.

In addition, this identification can explain why the so-called Triple Crown (Fig. 2B), or *hemhem*, strongly suggests it was designed to represent a cluster of *Psilocybes* (Fig. 2A and B), while the hieroglyph for the Egyptian Double Crown,  known as the *shmty* or *pschent*, comprising the White and the Red Crowns, was determined by two plants, and , each obviously intended to represent one of these crowns.

It is generally believed that the Red Crown represented Lower Egypt, the White Crown Upper Egypt, and the Double Crown the unification of these regions under King Narmer. However, Wainwright (1923) presented evidence that the Red Crown may have actually originated in Upper Egypt.

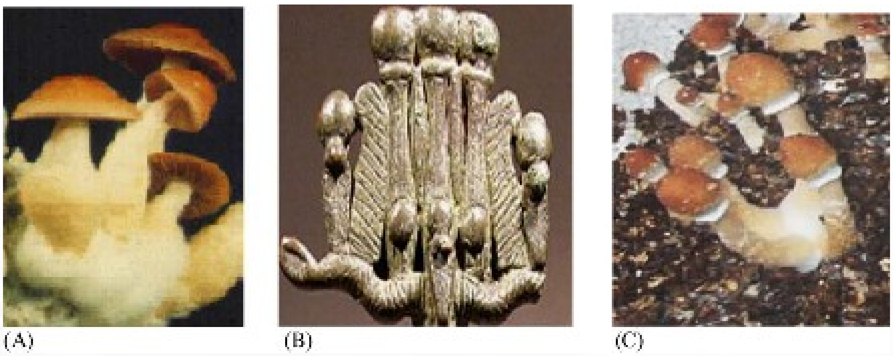

Fig. 2. Different stages of *Psilocybe cubensis* primordia (A and C) represented by the Triple Crown, or *hemhem* (B).

In any event, no theory has explained what either the Red or the White Crown was designed to represent, why both crowns were determined by plants, or why an enigmatic inscription in the tomb of the Fourth Dynasty Pharaoah Unas clearly states, "He has eaten the Red Crown, He has swallowed the Green One [and] delights to have their magic in his belly." (Faulkner, 1998, Utterance 274).

Lefebvre (1949) theorized that the Red and the Green Crowns, or *wadjet*, were the same crowns because the Egyptian word for green referred to things that were fresh, young, and prosperous, in agreement with the botanical nature of the Double Crown's determinant. However, considering the Egyptian practice of using green to signify plants (Wilkinson, 1994) in view of: (1) the evidence that the White Crown was originally designed to represent a *Psilocybe cubensis* and (2) the Egyptian practice of personifying the White Crown as Osiris who, as for reasons discussed below, was often painted green (Fig. 22), the Green Crown could have also, or alternatively, been another name for the White Crown.

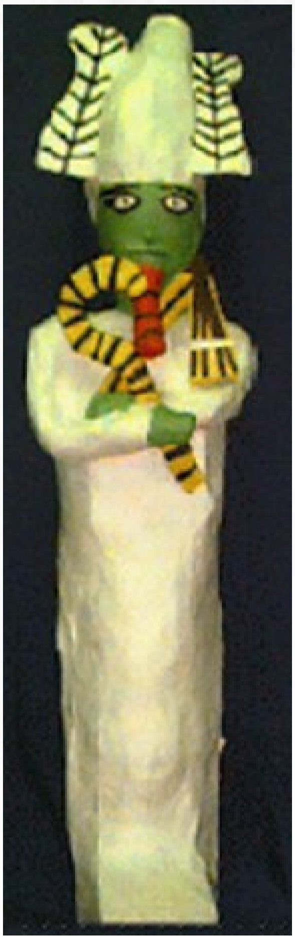

Fig. 22. Osiris as a green God.

In any case, Egyptologists have interpreted the above statement as a metaphorical reference to, for example, Upper Egypt swallowing Lower Egypt, whereas these statements can and should have been taken literally, particularly considering that the practice of wearing edible plants, especially psychotropic ones, as headdresses was widespread in antiquity. For example, Fig. 3 depicts: (1) the head of a Greek deity, often identified as Demeter, wearing a crown depicting the poppy capsules that yield opium; (2) two versions of the Egyptian Nile God Hapi, one wearing a papyrus crown and the other psychotropic lotus flowers (Emboden, 1978); (3) a Hawaiian helmet sporting mushrooms that Hoffman (2002) argued were entheogenic.

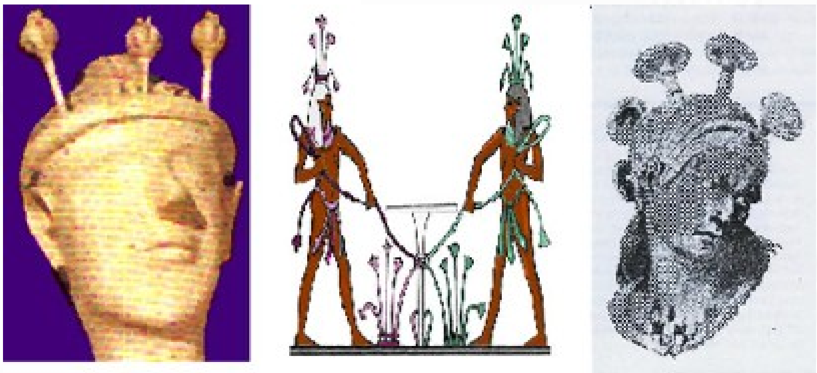

Fig. 3. (Left) Greek deity, often identified as Demeter, wearing a crown bearing the poppy capsules that yield opium. (Center) Two versions of the Egyptian Nile God Hapi, one wearing a papyrus crown and the other wearing entheogenic lotus flowers. (Right) Hawaiian helmet sporting mushrooms that Hoffman (2002) identified as entheogenic species.

Dikov (1971) found petroglyphs of humanoid figures wearing strikingly similar, mushroom-like headdresses high on a cliff in Chukchi Eskimo territory (Fig. 4, left), where the word for intoxication literally means "bemushroomed" (Wasson, 1968), and glyphs of similarly crowned figures carrying mushrooms were found in the Tassili-N-Ajjer region of the Sahara (Fig. 4, right) from which people may have migrated eastward to Egypt to escape the region's desertification. Although this region is currently arid, between 10,000 and 5500 BPE, during which this art was produced, the region had large lakes and forests, which included conifers and oaks. It can therefore be inferred that some of the mushrooms in this art were *Amanita muscariae*, which typically grow in mycorhizal relationship with these trees and birch.

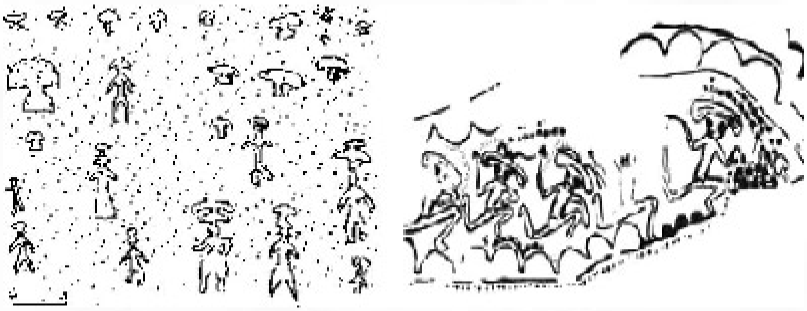

Fig. 4. (Left) Glyphs of mushroom-crowned humanoids on cliffs in Chukchi region of Russia. (Right) Pictures of similarly crowned beings carrying mushrooms on cave walls in the Tassili N-Ajjer region of the Sahara.

In fact, not too far from these Saharan glyph is one of a dancer whose head and neck seemingly comprise a primordial *Amanita muscaria* (Fig. 5B) (Samorini, 1992), and a glyph of a humanoid bee (Fig. 5A), who appears to be a shaman, covered with mushrooms (McKenna, 1992; Samorini, 1992), which Lhote (1973) interpreted as oars, and Mori (1975) as flowers. Of particular interest here is the pharaoh's use of the bee to symbolize that they were "bee-kings."

Still another Saharan glyph depicts a humanoid figure that appears to be defecating mushrooms that Samorini (1992) interpreted as *Psilocybes* based on this mushroom's coprophilia. However, this glyph may have been specifically designed to suggest that the depicted person was defecating the remains of previously ingested *Psilocybes* that would again grow into *Psilocybes*. In any case, Samorini (1992) concluded from these paintings that "there are at least two species [of mushrooms] one of which is small and topped with a 'papilla' (a characteristic it would share with most known hallucinogenic *Psilocybes*) and the other of which is larger (like

Boletus or *Amanita*)."

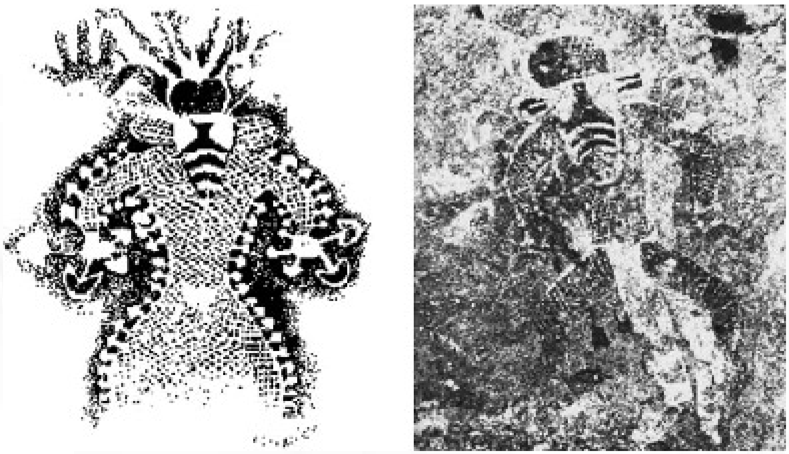

Fig. 5. (Left) Neolithic drawing of bee-headed humanoid from Tassili region of the Sahara. (Right) Mushroom-headed dancer from the same region.

Egypotologists have unanimously believed that the ancient Egyptians neither had nor ingested mushrooms, let alone entheogenic species. But the Egyptian climate, like the Sahara's, was far moister in prehistory than it is today, and Fig. 6 shows Egyptian glyphs depicting humanoid figures with mushrooms growing from their heads and ears that strikingly resemble pots from Mexico shaped like people with mushrooms growing from their ears (Schultes and Hoffman, 1992).

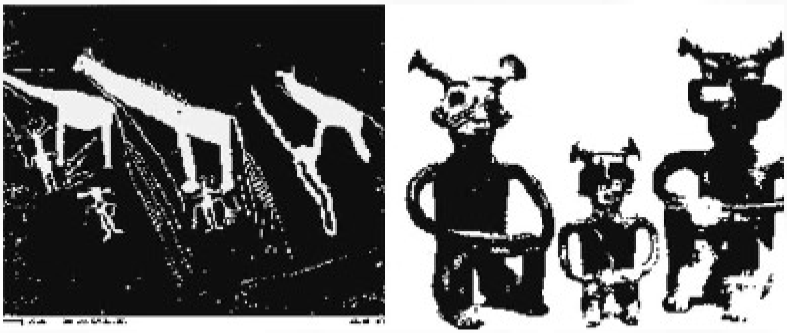

Fig. 6. (Left) Glyphs of beings with primordial mushrooms growing from the top of their heads and ears from El Hosh, Upper Egypt. (Right) Mexican pottery depicting people with mushrooms growing from their ears (Schultes and Hoffman, 1992).

These Egyptian glyphs, catalogued by Winkler (1938-1939), were found at El Hosh, in the Upper Egyptian region associated with the White Crown, not too far from which are other glyphs (Fig. 7) that can now be fairly reliably identified as phallic stage *Psilocybes* emerging from their primordia.

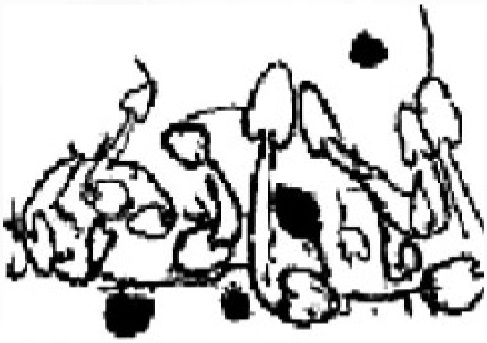

Fig. 7. Glyphs of phallic *Psilocybes* emerging from their primordia at El Hosh, Upper Egypt, the region the White Crown was associated with.

This identification can also more than adequately explain why the White and Triple Crowns were often worn on ram or cattle horns (Fig. 2B): *Psilocybes* tend to grow on the manure ruminants deposit in pastures, and the horns were evidently intended to suggest that these ruminants carried *Psilocybes* in their digestive systems. The Egyptians therefore sanctified the dung beetle, or scarab, for the apparent wisdom it showed rolling this manure into balls, from which *Psilocybes* would then often emerge.

The Egyptians then associated this beetle with the sun, apparently because *Psilocybe* ingestion typically causes people to see the world bathed in or emitting a bright, white or golden, mystico-religious light, while Egyptian artists often depicted the scarab pushing the sun across the sky, and *Psilocybe* caps as miniature suns.

A well-known principle of sympathetic magic held in antiquity, as it still does in some tribal societies, that the spirit of a food is ingested along with the food, and subsequently manifests itself in the eater: for example, members of many tribal societies believe that eating lion meat will make them strong like the lion, whereas eating rabbit meat will make them fast, or timid, like the rabbit. Accordingly, the ancient Egyptians who perceived this mystico-religious light after ingesting *Psilocybes* would have, and apparently did, attribute the phenomenon to the ingestion of the mushroom's indwelling light, hence solar, spirit, in full agreement with Spess's (2000) belief that entheogenic plants were anciently regarded as repositories of a divine light. By the same principle, these people would have also attributed that light to the manure from which the *Psilocybes* seemingly emerged, especially because the manure released light when burned.

Egyptian iconography is therefore loaded with many other structures that were clearly designed to depict mushrooms, though Egyptologists, for reasons explained below, have failed to identify these structures as mushrooms. Perhaps nowhere is this failure more evident than in the case of Egyptian ear studs, such as those depicted in Fig. 8. According to The Boston Museum of Fine Arts Catalogue (1982) depicting these studs, and Aldred's (1971) analysis of similar studs, they obviously resemble mushrooms. Yet, no explanation for this resemblance was given in these works, implying that it must be coincidental.

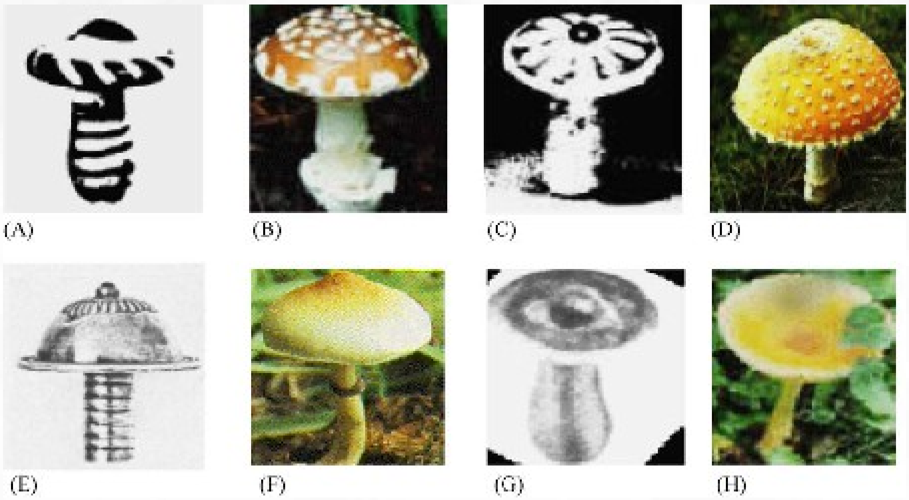

Fig. 8. 18th-19th Dynasty Egyptian ear studs (A, C, E, and G) were evidently designed to stylize the entheogenic *Amanita pantherina* (B), *Amanita muscaria* (D and H) and *Psilocybe* (*Stropharia*) *cubensis* (F) mushrooms.

On the contrary, the resemblance can be explained far more instructively by recognizing that studs A and E evoke the image of the entheogenic *Amanita pantherina* (Fig. 8B) and *Amanita muscaria* (Fig. 8D and H), typically found along the coast of North Africa (Festi and Bianchi, 1991), while stud E evokes the image of the coprophilic, gold-capped *Psilocybe* (*Stropharia*) *cubensis* (Fig. 8F). More specifically, the marginal whorl on the cap of stud A and the large rosette on the cap of stud C were evidently designed to suggest the patterns on the caps of *Amanita pantherinae* and *Amanita muscariae*, while the smaller rosette on the cap of stud E was evidently designed to suggest the dark circle on the caps of many *Psilocybes* (Fig. 8F) and some *Amanita muscariae* (Fig. 8H). The spirals on the stems of these studs were evidently designed to suggest the rings on the stems of the above-mentioned mushrooms; the central protrusions on the studs' caps were evidently designed to suggest the central protrusions on the caps of the so-called umbonate varieties of these mushrooms and, the caps of similar studs (Fig. 8G) have central depressions, which were evidently designed to suggest the depressions on the caps of so-called umbilicate varieties of these mushrooms (Fig. 8H). In particular, the incredible likeness between stud G and the umbilicate, gold, *Amanita muscaria* (Fig. 8H) cannot be easily ignored. Many studs were therefore made mainly or entirely from blue faience or lapis lazuli to evoke the blue color that distinguishes *Psilocybes* from similar looking mushrooms.

Other studs were made by combining blue with the reds, whites, and yellows of the *Amanitae* (Reisner, 1923; Aldred, 1971; Boston Museum of Fine Arts, 1982). And still other studs were made of gold to evoke the color of the gold-capped varieties of these mushrooms.

These mushrooms have traditionally been known for their ability to induce mystico-religious phenomena commonly known as ego death and spiritual rebirth which, as shown below, were apparently a central, though well-hidden, element in many Egyptian religious rituals long before relatively realistic representations of these mushrooms appeared as ear studs in the Middle Kingdom. The reasons this jewelry appeared relatively late in Egyptian history are unknown, but its appearance may have been caused by a relaxation in a long standing policy of secrecy stated in the previously cited passage of the Egyptian *Book of The Dead*, just as secrecy has traditionally surrounded the ingestion of entheogenic mushrooms elsewhere in the world (Allegro, 1969; Wasson, 1980).

Regardless of why these representations of mushrooms appeared full blown so late in Egyptian history, it can be inferred that these ear studs, many examples of which were found in tombs at Abydos, Kerma, and Amarna, were more than just meaningless pieces of jewelry that only coincidentally resemble mushrooms. These studs were almost certainly intended to represent entheogenic mushrooms, like those growing from the ears of the bemushroomed Egyptians depicted at El Hosh. Based on the anciently widespread belief that symbols, especially amulets, were imbued with the power of the things they represented, these ear studs were probably used funereally in attempts to spiritually rebirth, and perhaps even physically resurrect, dead Egyptians, based on the also anciently ubiquitous belief that such mushrooms were plants of immortality-hence, The Food of Gods (McKenna, 1992).

4. The mycological origin of Egyptian crowns as told in *Cheops and the Magicians*

The theory that the White and Triple Crowns were designed to represent *Psilocybe cubensis* primordia can be supported by noting that this mushroom is commonly cultivated today in essentially the same way an ancient Egyptian story, known as *Cheops and the Magicians*, allegorically describes how crowns were bestowed on the newborn rulers of Egypt's Fifth Dynasty in a document known as *The Westcar Papyrus*. That is, *Psilocybes* are commonly cultivated today by placing grain in containers, inoculating the grain with spores, and keeping the grain moist for approximately 14 days while the spores incubate. Similarly, in *Cheops and the Magicians*, crowns are bestowed on Egypt's rulers by deities who had hidden them in barley that they exposed to a storm and later incubated in a storeroom for 14 days (Lichtheim, 1975).

The manuscript fails without explaining what happened to the hidden crowns, which Lichtheim (1975) suggested were "magical tokens of kingship," rather than crowns, in an obviously strained effort to explain the peculiarity of crowns being hidden in barley. But considering: (1) the striking resemblance the typical, and particularly the atypical, White Crowns in Fig. 1 bear to *Psilocybe cubensis* primordia; (2) the anciently widespread practice of wearing psychotropic mushrooms and other plants as crowns; (3) the rupestrian and iconographic evidence that the ancient Egyptians had *Psilocybes*; and (4) the well-known practice of cultivating *Psilocybes* on grain, it can be inferred with a fair degree of assurance that *Cheops and the Magicians* was designed to allegorically explain that Egypt's crowns were originally *Psilocybes* that grew from barley.

It is apparently for this reason that the hieroglyph for the White Crown (Fig. 9) comprises what can now be identified as a *Psilocybe* primordium, ostensibly as the White Crown, over the Egyptian hieroglyph for a basket, evidently designed to represent the barley from which the crowns emerged in *Cheops and the Magicians*. Hence, in Fig. 10, the Egyptian solar deity Horus holds the White Crown up to his face in a bowl or basket to signify that the crown is edible (Fig. 10).

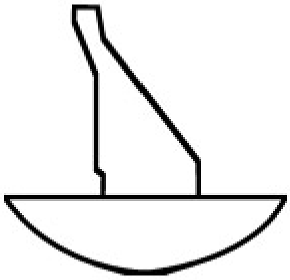

Fig. 9. White Crown hieroglyph.

The theory that the crowns in this story were *Psilocybes* can also explain why the story's author decided to create a storm out of the blue. Lichtheim (1975) attempted to explain this seemingly unnecessary peculiarity as a reason for the deities to return to the house. But the deities did not need an excuse, for they had already decided to return to the house to bestow crowns on the royal children before the storm even arose. In fact, it was apparently the deities themselves who created the storm, for the pertinent passage Lichtheim (1975) translated as, "Then they let a sky of storm and rain come up," can be translated even better as "Then they caused the storm and rain to come up."

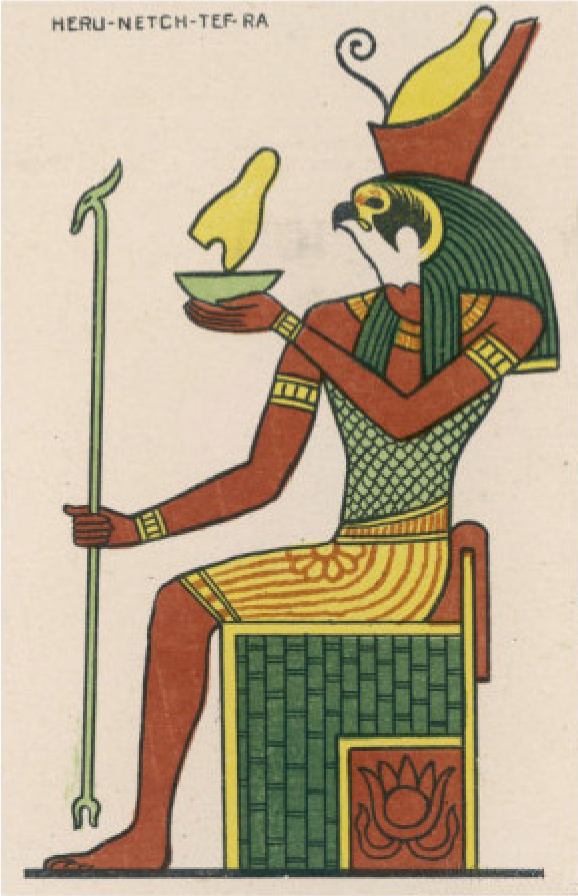

Fig. 10. Horus, wearing the Double Crown, holds the White Crown up to his face in a bowl or basket to signify that it is edible and, perhaps, that he is preparing to eat it.

The story's author evidently decided to have the deities create the storm because the emergence of mushrooms typically follows rain, thunder, and lighting in the world's fungal folklore, as (Wasson *et al.*, 1986) pointed out in the definitive work on that relationship. The author of *Cheops* therefore cleverly had the deities create the storm to moisten the barley, thereby presaging the appearance of the mushrooms it held.

The theory that the hidden crowns were *Psilocybes* finds still more support in its ability to explain why the maid hears music and dancing coming from the barley exactly 14 days after the barley had been exposed to the storm: the fruiting cycle of many *Psilocybes* is approximately 14 days (Stamets, 1996), and mushrooms, especially entheogenic species, were typically personified in antiquity, apparently based on the same tendency to personify plants that led modern commercial artists to personify, for instance, a banana as Chiquita Banana and a peanut as Mr. Peanut.

For example, Fig. 11A depicts: (1) the well-known Venus of Willendorf figurine, dated to approximately 25,000 BPE, and (2) a primordial *Amanita* (Fig. 11B). Comparing these structures, it becomes apparent that the figurine's strange coif was designed to personify the characteristically knotted cap of a primordial *Amanita*; the figurine's steatopygia was designed to personify the primordium's bulbous base; the figurine's strangely slender, segmented, and handless arms were designed to personify the dentate ring the *Amanita* ruptured veil leaves on the mushroom's stem; the red ochre the figurine was covered with was intended to color it the color *Amanita* caps often display (Berlant, 1999).

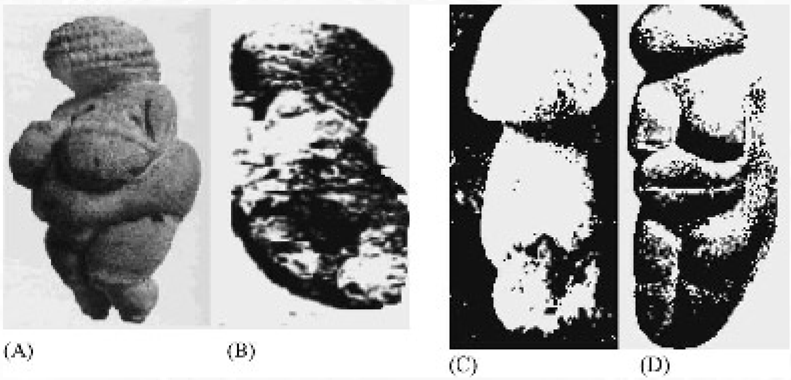

Fig. 11. (A) Venus of Willendorf; (B) primordial *Amanita muscaria*; (C) horse mushroom primordium; (D) anthropoid female figurine from Chiozza di Scandino, Italy (Berlant, 1999).

For the same reasons, the developing Horse Chestnut primordium (Fig. 11C) strikingly resembles the anthropoid figurine from Chiozza di Scandino, Italy (Fig. 11D) (Berlant, 1999).

That ancient Egyptian artists personified mushrooms, just as their European counterparts did, is readily apparent by observing that a Lawn Gallerina (Fig. 12A) was evidently personified in the Egyptian figurine with a conspicuous medial cleft (Fig. 12B); that a predynastic, Egyptian figurine (Fig. 12C) strikingly resembles the maturing *Amanita brunnescens*, or cleft foot, mushroom (Fig. 12D); that the three anthropoid, predynastic, Egyptian figurines beginning on the right in Fig. 13 strikingly resemble both the *Psilocybe cubensis* primordium on the far left and the White Crown on its immediate right (Berlant, 1999).

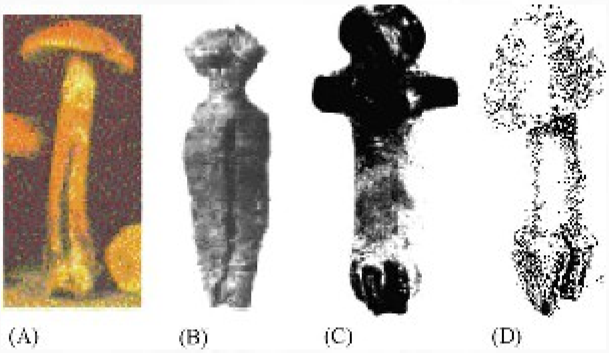

Fig. 12. Lawn Gallerina (A) personified in Egyptian figurine with conspicuous medial cleft (B), and maturing *Amanita brunnescens* (C) personified in anthropoid, predynastic, Egyptian figurine with conspicuous basal cleft (D).

For the same reasons, the anthropoid Canaanite figurines in Fig. 14B and C reveal that they were designed to represent a cluster of *Psilocybes*, just as the Triple Crown (Fig. 14D) apparently was. Since the Egyptians traded extensively with the Canaanites and other Levantine peoples, it is very possible that this trade included *Psilocybes* and *Amanita muscaria* that grew in mycorhizal relationship with the famous cedars of Lebanon, as they do with the less famous Moroccan cedars. Mabry (2000) quotes Dr. C. Bas of the Rikjksherbarium/Hortus Botanicus in Leiden, Netherlands, who studied the *Amanitae* for over 25 years, as having said:

> "It seems to me that it is; very probable that the *Amanita muscaria* grew (or still grows), in the Lebanon with *Cedrus* ... *Cedrus* is mentioned as a partner of *Amanita muscaria*. In Morocco grows *Cedrus atlanticus*, in Lebanon, *Cedrus libanotica*. But the differences between the two species is; very small. Moreover, the two Pinus species ... are widely cultivated around the Mediterranean." (Cited in Mabry, 2000)

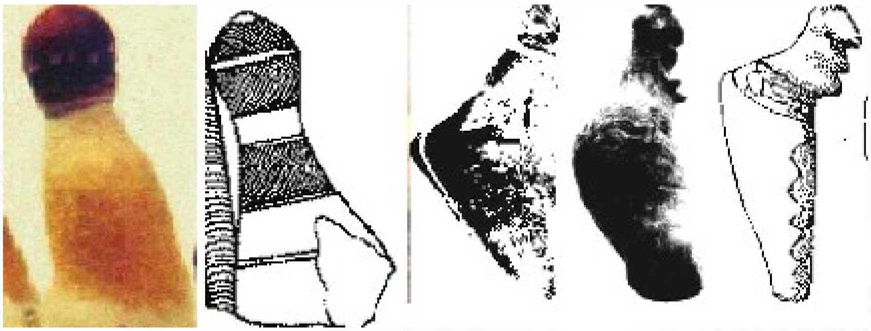

Fig. 13. *Psilocybe* primordium (left) symbolized by the White Crown (center) and personified by three, anthropoid, predynastic Egyptian figurines (right).

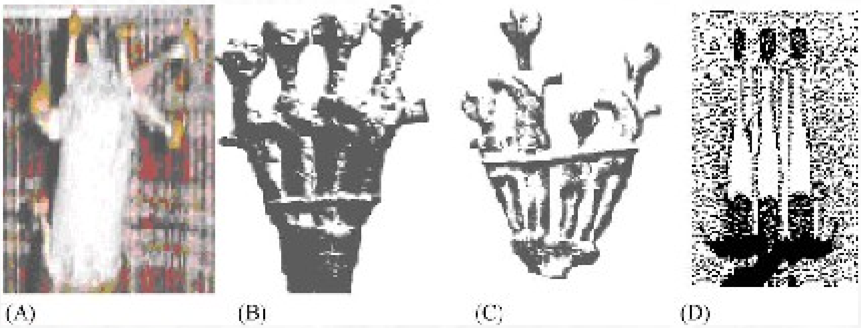

(A) (B) (C) (D)

Fig. 14. *Psilocybe* cluster, here on growth media (A) personified in Canaanite figurines (B and C) and symbolized by Egyptian Triple Crown (D).

Ancient artists who personified entheogenic mushrooms may have also done so for another reason, however: i.e., people who ingest such mushrooms often see mushroom-like beings singing, dancing, and gesturing in ways that are culturally dependent. In Siberia, for instance, these beings are regarded as helpers that usually lead "bemushroomed" individuals on journeys through realms that are regarded as spiritual, rather than illusory (Wasson, 1968), while in Central America these spirits are often referred to as "little children" or "clowns" (Munn, 1973; Wasson, 1980).

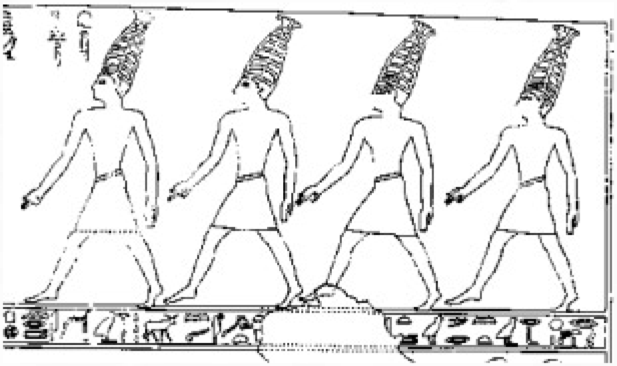

Fig. 15. Muu dancers wearing woven, basket-like, variations of the White Crown.

In view of this analysis, it is not coincidental that the Egyptian word *muu*, for the so-called *muu* dancers, (Fig. 15) who were responsible for bringing the souls of the dead to the afterworld, referred to jesters, buffoons, and dwarfs (Budge, 1978; Faulkner, 1986), for these dancers were evidently originally the Egyptian analogues of the dancing mushroom spirits people have typically seen after ingesting entheogenic mushrooms. This analysis is in full accord with: (1) the belief that the *muu* were originally dwarfs, just as the word for them implies (Moret, 1927); (2) the belief that the *muu* crown was a variation of the White Crown (Abubakr, 1937);

(3) the belief that the *muu* were personified crowns (Altenmuller, 1975), for the *muu* were indeed originally personifications of the *Psilocybes* their crowns were designed to represent.

The Egyptian shamans who personified the spirits that seemingly dwelled in the entheogenic mushrooms they ingested also deified these spirits as, for example: (1) the minor deity Nekhbet, the so-called Lady of El Kab, and (2) the major deity Osiris, the so-called "Lord of the White Crown [and he] ... whose White Crown is lofty." (Collier, 1996). Hence, the Papyrus of Ani explicitly calls Osiris "O thou [you] White Crown of the divine form!" (Budge, 1967).

Indeed, it is precisely because the Egyptians personified entheogenic mushrooms, on the one hand, as crowns, but on the other hand, as deities that the aforementioned inscription in the tomb of Pharaoh Unas also states "The Pharaoh is the bull of the sky ... who lives on the being of every god ... their big ones are for his morning meal, their middle sized ones are for his evening meal, their little ones are for his night meal" (Faulkner, 1998, Utterance 273-274), apparently in reference to the differently sized mushrooms, personified as Gods, that Pharaoh ingested.

Because Osiris was evidently originally the personification of a *Psilocybe*, the Papyrus of Ani says of him "Thy head is blue [like] lapis lazuli" (Budge, 1969a), obviously in reference to the tendency *Psilocybe* caps have of turning blue when touched, while the Egyptian Blue Crown, cap-crown, or *khepresh*, was designed to represent such a cap.

Because Osiris was originally a personified mushroom, the symbol Budge identified with him at the god's cult center at Abydos, where many entombed ear studs were found, was a plumed mushroom transected by a serpent (Fig. 16). Feathers were, for obvious reasons, used ubiquitously in antiquity as symbols of flight, especially that of the soul, and serpents were anciently known ubiquitously for their poisons and their ability to shed their skins, in an act that clearly would have evoked, and apparently did, the ego death and spiritual rebirth that entheogenic mushrooms often induce.

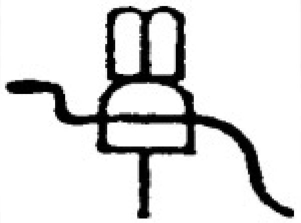

Fig. 16. Plumed mushroom and serpent symbol that Budge associated with Osiris at the god's cult center at Abydos.

Serpents were therefore intimately associated in antiquity with mushrooms, especially toxic and entheogenic species (Pliny the Elder, Naturalis Historiae XXII, line 95; Allegro, 1969; Nicander, 1953), and the Egyptians often surrounded the *Psilocybe cubensis* primordia on their crowns with both feathers and serpents to indicate that the mushrooms these crowns represented contained toxins that could confer immortality and divinity on people who ingested them. Hence, the aforementioned inscription in Unas's tomb also states, "It is the serpent-raised head who guards them for him," evidently referring to these serpents as guardians of the sacred mushrooms.

Because Osiris was originally a personification of a *Psilocybe*, which the White Crown symbolized, the picture of him rising up from a basket, enveloped in the wings of his consort Isis (Fig. 17), is entirely equivalent to the hieroglyph of the White Crown in a basket (Figs. 9 and 10).

Besides having been considered a personification of the White Crown, the Egyptians regarded Osiris as the personified spirit of barley; for example, the Coffin Texts quote Osiris as saying, "I am Osiris ... I am barley ..." (de Buck, 1947). Osiris therefore appears in Fig. 18 covered by and shedding the barley he personified with the Atef or Osiris crown, comprising the White Crown flanked by feathers, literally growing from his head, just as *Cheops and the Magicians* explains allegorically how the White Crown grew from the stored barley.

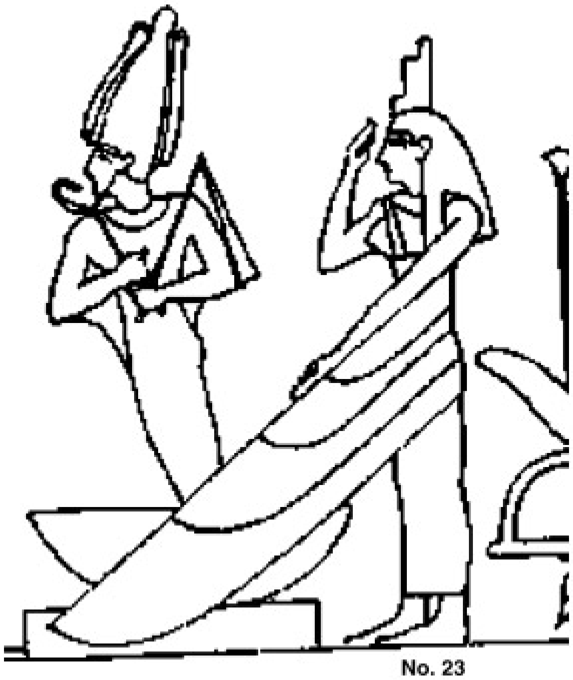

Fig. 17. Osiris rising up from a basket, enfolded in the wings of Isis is symbolically equivalent to the White Crown hieroglyph (Fig. 9).

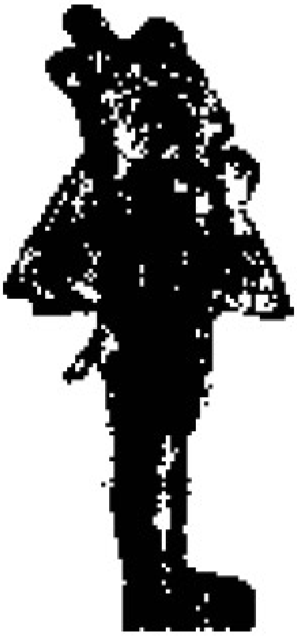

Fig. 18. Osiris shedding the barley he is personifying with a *Psilocybe* crown growing from his head, ostensibly as a crown.

Osiris was therefore typically depicted monopodially with arms akimbo (Fig. 19, left), obviously so he would look remarkably like a mushroom (Fig. 19, right), especially to anyone who was privileged to the esoteric information that Osiris's original nature was mycological. In fact, because the practice of personifying mushrooms as monopodial beings was widespread in antiquity, mummies were apparently fashioned with a single or fused legs and arms akimbo to look like mushrooms, as explained more below vis a vis the *tekenu*.

> This is a coffin-like vessel of granite which stands on supports in a greater basin. In it lies the golden image of the god. The vessel is filled with earth, which is intermixed with sacred material-incense, precious stones and so on. Seeds of differing kinds are embedded into this mixture, and their germination and growth signify the revival of the dead. (Otto, 1968, p. 58)

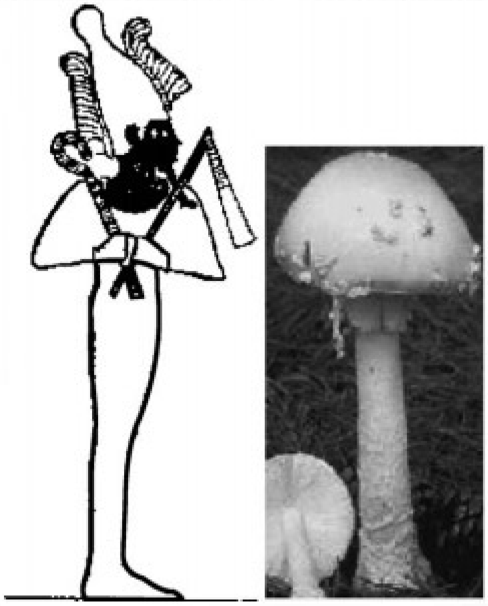

Fig. 19. (Left) Osiris in his typical mushroom-like pose. (Right) *Amanita muscaria*. Particularly noteworthy is the striking resemblance Osiris's hands bear to the annulus, just under the mushroom's cap.

Because Osiris was a personifed *Psilocybe*, the Egyptians also constructed beds of straw shaped like Osiris, to plant *Psilocybes*:

Plants subsequently grew from the straw and earthen image of Osiris, though the nature of these plants and the reason they were associated with Osiris's resurrection have never been adequately explained. It is generally believed that the plants were probably barley, but if so, there would have been no reason to construct a bed of precious stones and straw.

This practice can now be adequately explained as a ritualized personification either of the practice of growing *Psilocybes* from grain, as *Cheops and the Magicians* allegorically describes, or the practice of growing *Psilocybes* from straw and mycelia, known as spawn. In a modern version of the latter technique, used by people who typically grow *Psilocybes* for recreational use, a plastic cooler or tub is filled with vermiculite, just as the Egyptians filled Osiris's casket with earth and stones. A bed of sterilized straw is placed over the vermiculite, just as the Egyptians placed papyrus or straw over their stones, and *Psilocybe* mycelia, or spawn, is placed over the straw. Shortly thereafter, *Psilocybe* primordia begin sprouting, and about two weeks later the *Psilocybes* are mature and ready to eat.

It was apparently from ingesting these *Psilocybes* and experiencing the spiritual rebirth they could induce that Egyptian kings derived their knowledge of what they subsequently called the "Second Birth." This birth was then attributed to the spirit of the sun passing first into the straw, then into the *Psilocybes*, and finally back into the deceased Pharaoh, who was presumably then resurrected as the solar deity Osiris.

Mabry (2000) recognized that Osiris was a personified mushroom, though Mabry argued that Osiris personified the *Amanita muscaria*. Mabry's suspicion finds a great deal of support in its ability to explain why, for example, the Egyptians gave valiant warriors golden flies, like those in Fig. 20, upon their induction into the so-called Order of the Golden Fly. No comprehensive study has ever been done on the significance of this order or its symbol, though Egyptologists have speculated that the Egyptians must have regarded the fly as brave.

Indeed, the *Amanita muscaria* has traditionally been known in societies where it is still ingested for its ability to greatly increase a person's strength and bravery, and it has therefore been implicated as the drug Viking warriors, known as berserkers, took before going into battle (Wasson, 1968). Moreover, the *Amanita muscaria* is commonly called the Fly-Agaric, because it attracts and reputedly stuns or kills flies. Hence, the fly has often been used to symbolize this mushroom and would have indeed been an appropriate ancient Egyptian symbol of strength and bravery.

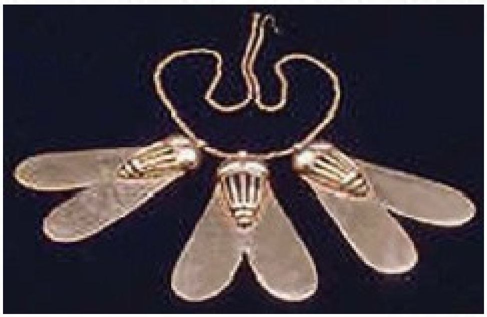

Fig. 20. A necklace of golden flies from the tomb of Queen Ahhotep, mother of Ahmose I.

Mabry's theory that Osiris personified the *Amanita muscaria* finds still more support in its ability to explain the enigmatic ritual of the *tekenu*, during which an Egyptian shamanic priest was pulled on a sled while lying in the fetal position wrapped completely in a bull's hide, emerging later in the same distinctly mushroom-like form that Osiris typically manifests (Fig. 21).

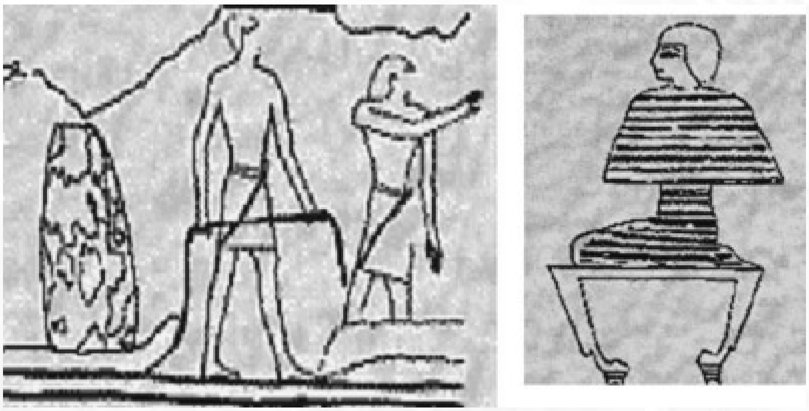

Fig. 21. Tekenu wrapped in a bull's hide representing an *Amanita muscaria* primordium. The priest eventually emerges in the same distinctly mushroom-like pose that Osiris typically manifests, in a position to administer the sacred mushroom cap he then personified.

The *Amanita muscaria*'s mottled red and white cap, combined with its ability to greatly increase strength, led ancient mytho-poets and artists to personify it as a bull (Wasson, 1968; Hoffman *et al.*, 2002; Ruck *et al.*, 2004). It can therefore be inferred that the *tekenu* ceremony was designed to recapitulate the birth of Osiris, whose spirit the Egyptians believed dwelled in barley and, consequently, in the parasitic, entheogenic mushrooms that absorbed the spirit of barley. Having been reborn as the mushroom deity, the priest was then in a position to administer the sacred mushroom cap he himself personified in the rebirthing ceremony appropriately known as "Opening of the Mouth."

The evidence presented above suggests further that the Egyptians were also ritualistically ingesting entheogenic *Amanita pantherina*, which can explain why Osirian priests typically wore panther skins.

In Fig. 23, Wepawet (*Upuaut*), the dog or jackal God, known as The Opener of The Ways, stares at Osiris's mushroom embodiment, perhaps because the predynastic Egyptians used dogs to search for the mushrooms Osiris personified, just as modern mushroom hunters often do. That this mushroom was probably a *Psilocybe* can be inferred by noting that standing on the right and left of it are non-steatopygous, ithyphallic, monopodial beings, evidently representing personified *Psilocybes*, rather than steatopygous *Amanita muscaria*, primordia. Their erect phalluses were apparently designed to resemble arms bearing the mushrooms these primordia yield, in accordance with the anciently ubiquitous practice of representing mushrooms as phalluses (Allegro, 1969).

These puppet-like creatures are evidently depictions of those used in processions honoring Osiris who, according to Herodotus (2.42), was the Egyptian analogue of Dionysus, the Greek God of intoxication. According to Egyptian legend, Osiris was dismembered by his brother Set and re-assembled by his consort Isis, except for his phallus, just as the Titans murdered Dionysus who was then represented by a disembodied phallus (Ruck, 2005). During this procession, led by a flautist and singers praising Osiris, the hinged, erect penises of these puppets, about 18 in. tall, were made to bob up and down by women who carried them through villages.

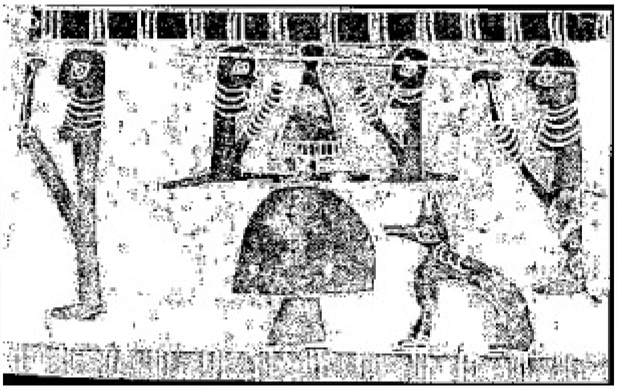

Fig. 23. The dog-God Wepwet (*Upuat*) pointing to Osiris's mushroom embodiment, surrounded by personified, ithyphallic, monopodial, *Psilocybe* primordia (from Mabry, 2000).

Herodotus claimed that the seer Melampus, who presumably introduced the worship of Dionysus to the Greeks, was well aware of this Egyptian procession, but did not quite understand it. Nevertheless, it was Melampus who reputedly transformed this procession into the Dionysian parade of the phallus (Ruck, 2005).

Because Osiris was originally an entheogenic mushroom, he also figures prominently in an Egyptian legend wherein he was resurrected after ingesting a structure the Egyptian called the *utchat*, now known commonly as the Eye of Horus.

The Eye of Horus (Fig. 24) has generally been regarded as a solar, lunar, and ornithological symbol because Horus was a solar and lunar deity with the head and, often, body of a hawk. But the Eye of Horus was heretofore unexplainably also a plant from which the Egyptians made an elixir and cakes they believed could confer immortality on people, about which E.W. Budge wrote:

> The gods nourished themselves with celestial food which was supplied to them by the Eye of Horus, that is to say, they supported their existence on the rays of light which fell from the sun which lit up heaven, and they became beings whose bodies were wholly of light. According to one myth the gods themselves lived upon a 'wood or plant of life,' which seems to have grown near the great lake in Sekhet-hetep, round which they were wont to sit .... In other places we read of 'bread of eternity' and 'beer of eternity.' (Budge, 1969a,b, vol. I, p. 164)

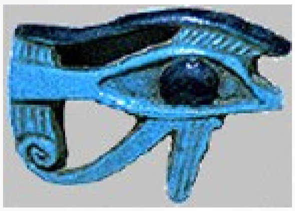

Fig. 24. An Egyptian *utchat*, representing the Eye of Horus, Re and Thoth, as well as a plant that could reputedly yield an elixir of immortality.

The Egyptians therefore included this plant of immortality in the ale and cakes they entombed with dead Egyptian kings, in accordance with the legend in which Osiris, whom every king aspired to become, was resurrected after he somehow ate the Eye of Horus (Griffiths, 1980). The entheomycological significance of this plant, and the reason Egyptian priests believed it could confer immortality on those who consumed foods made from it, can now be fully understood by noting that eyes are intuitively appropriate symbols of entheogenic mushroom caps, because such caps are ovoid like eyes and typically have a central protrusion or depression suggesting an eye's iris (Ott, 1969).

In addition, eyes, like suns, are very appropriate symbols of entheogenic mushroom caps, because ingesting such caps induces the luminous phenomena that solar and lunar symbols so aptly describe metaphorically.

Hence, such caps were reputed to give people the ability to see into other realms of reality. Thus, Odin, while hanging, like a personified rhizophyllic mushroom, from the sacred Yggdrasil tree, gained the gift of omniscience and prescience only after he drank from a well into which he had dropped his eye.

The theory that the Eye of Horus was an entheogenic mushroom cap can also be supported by noting that the Egyptians personified this eye in the very same way ancient Hindu priests personified Soma. More precisely,

1. The Egyptians personified Horus and Osiris as eyes, just as the Rg Veda describes the Soma plant and its elixir as an eye (Rg Veda I 875ab; IX 94; IX 10 ab).
2. The Egyptians personified Horus and Osiris as the sun, just as The Rg Veda personifies the spirit of the Soma plant, which also yielded a divine elixir, as a luminous, solar deity (Rg Veda I, 4610ab; IX, 26c; IX, 275ab).
3. The Egyptians described Horus and Osiris as luminous lunar deities, just as the Rg Veda describes the Soma plant and its elixir as a luminous lunar deity (Rg Veda 8.082.08; 10.052.02: 6.039.03).
4. The Egyptians claimed that the Eye of Horus could confer immortality on those who consumed it, or an elixir made from it, just as the Rg Veda describes the Soma plant and its elixir as having the ability to confer immortality on those who consumed it (Rg Veda, 8.048.03; 1.091.06; 1.091.18; 8.048.12; 8.048.11).
5. The Egyptians associated or personified Horus and Osiris as hawks, just as the Rg Veda as well as the Taittiriya Samhita and Aitareya Brahmana, associate Soma with a hawk, claiming more specifically that this hawk brought Soma to India (Rg Veda 1.080. 02; 1.093.06; 8.082.09) (Taittiriya Samhita 6.1) Aitareya Brahmana (3.25-27).
6. The Egyptians believed the Eye of Horus was submersed in and then taken from the primeval waters, just as the Rg Veda claims that Soma plant emerged from the primeval waters, and was an earthly, consumable part of those waters (Rg Veda, IV58.1) (Lidova, 1995).

From the above and many other Hindu textual passages too numerous to mention, it can be inferred that the Eye of Horus was almost certainly the Egyptian analogue of Soma. R.G. Wasson argued convincingly that Soma was originally the *Amanita muscaria* (Wasson, 1968), and perhaps later, a Pilocybe. The theory presented in this paper fully supports Wasson's theory.

5. Discussion and conclusions

This paper contains textual and graphic evidence strongly suggesting that the Egyptian White and Triple Crowns were originally primordia of the entheogenic *Psilocybe* (*Stropharia*) *cubensis*, which an Egyptian tale known as *Cheops and the Magicians* allegorically attributed to barley. In addition, the paper contains textual and graphic evidence strongly suggesting that Osiris was the God of spiritual rebirth, because he originally personified *Psilocybes*, the *Amanita muscaria* and, probably, the *Amanita pantherina*. Finally, the paper theorizes that the plant known as the Eye of Horus, which Egyptians included in cakes and ales they concocted to spiritually rebirth the living and the dead, was intimately associated with Osiris, because this eye symbolized an entheogenic mushroom cap that was the Egyptian analogue of Soma.

One might ask why Egyptologists who have studied the above material for so many years could have missed the identities and relationships I have just elucidated. The reason for this is, I believe, several-fold. First, as the eminent philosopher of science, Kuhn (1962) pointed out, professional education often leads students to view things in the same way their professors viewed them, often to the extent that getting either group to view those things differently is very difficult, if not impossible. It was for this reason, coupled with the failure to realize that authority is not tantamount to truth, that the Aristotelian notion of heavier objects falling faster than lighter ones managed to survive for over 1600 years, and current theories about the origins and underpinnings of Egyptian religion have existed virtually unchanged for decades. The theory presented in this paper is a radical departure from those theories, but rests on the same body of textual and graphic evidence.

Second, Egyptologists, as a general rule, know little or nothing, and implicitly care even less, about how drastically entheogenic plants can affect one's world view, or the extent to which such plants have traditionally been used ritualistically in other cultures, for example, to commune with ancestors who, in many cases, were deities. Osiris was the pharaonic patriarch, and communing with him apparently involved ingesting his botanical embodiments, entheogenic mushrooms. This, just as the Greeks ingested Dionysus's botanical embodiment, the grape - or as Graves (1960) suggested, entheogenic mushrooms in wine - after which his spirit seemingly rose up and possessed them. Herodutus's belief that Osiris was the Egyptian analogue, if not predecessor, of Dionysus was thus well founded.

Third, entheogenic mushrooms are regarded as illegal drugs used in this culture mainly by young adults for recreation, and the effects these mushrooms induce are regarded as hallucinations or illusions. In contrast, the ancients held psychotropic plants and the effects they induced in high regard, to the extent that the ingestion of these plants was typically reserved for priests and seers. The implicit tendency of Egyptologists to regard entheogenic mushrooms disdainfully is therefore a cultural bias that has evidently had a prejudicial effect on the wealth of evidence that the ingestion of such mushrooms underpinned ancient Egyptian religion.

Finally, Egyptologists and laymen alike have romanticized the Egyptians and their deities from the very advent of Egyptology. The theory that Egyptian religion and culture was built around the practice of ingesting entheogenic mushrooms, which we now condemn, can create a cognitive dissonance that some people may never be able to resolve.

Introduction

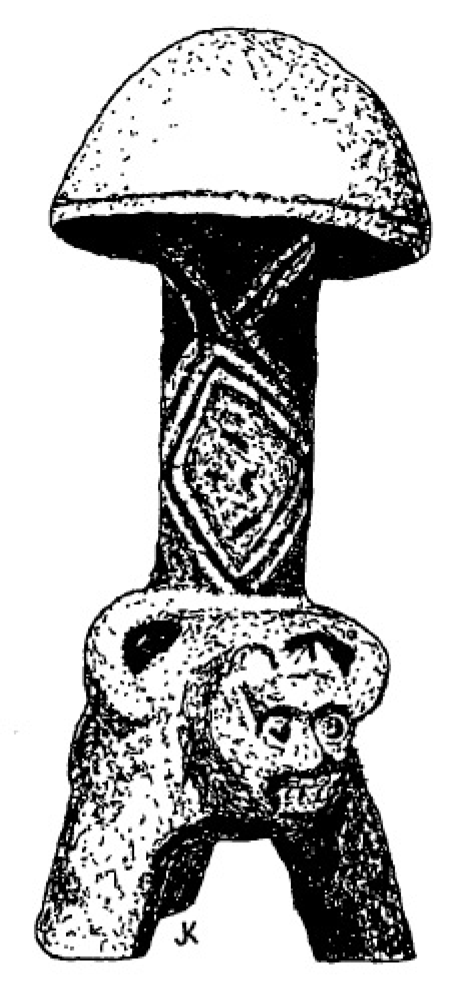
Traders and trade in ancient Mayan society are subjects of intense discussion and debate in anthropological journals. Archaeologists such as Muriel Weaver (1952: 57) and William Rathje (1972) believe that without an integrated system of exchange, administrated by an astute managerial class, the Maya might never have achieved the lofty cultural peaks of the Classic Period. Trade and a trader class were essential if life was to carry on smoothly. The Maya traded most everything: salt, feathers, rubber, obsidian, flint, igneous stone, honey, cochineal, jade, wax, polychrome vessels and a panoply of other necessary and superfluous commodities of daily and ritual life. Ancient Mayas desired (and needed) these goods with a passion.

An item of trade and a group of traders are presented in this article in the framework of a hypothesis: a model which involves the ancient Maya of Mesoamerica and their propensity to utilize and trade a unique commodity, psychotropic mushrooms. The aim of this article is not to rehash specious information concerning the significance that ritual hallucinogenic mushrooms may have had for Mayan peoples centuries upon centuries ago, but rather, to reinterperet the role and status of these sacred plants in ancient Mayan society.

The "Transcendental Interaction Model" examines the phenomena of the proliferation of exploitable hallucinogenic mushrooms in Mesoamerica and the possible ways and means that prehistoric peoples utilized them; as well as discussing prehistoric mushroom effigy stones and other symbolic iconography. The model's fundamental components have been developed in response to Dobkin de Rios' inference (1974: 148) that "it is possible that psychotropic mushrooms were important trade items in the southern highlands, where active commerce with other parts of Mesoamerica existed." And also in response to Köhler's (1976: 145) skeptical comment that "none of the rather speculative hypotheses so far proposed offers a convincing explanation." Additionally, while Dobkin de Rios first mentioned the *existence* of a mushroom connection, she did not pursue the question of the *necessity* of that connection, given the sociocultural and political conditions of the time.

The mushroom mystique of the ancient Maya is made more comprehensible in the context of ordinary, business-as-usual mushroom trade. To be sure, the Transcendental Interaction Model is a speculative hypothesis of ritual mushroom use derived from "limited inferences" (Plog 1977: 138) that archaeologists are able to make about ancient Mayan religion, society and trade patterns. It is also without question a somewhat radical hypothesis. Emboden (1979: 91), in discussing advances of historical knowledge, observes: "The structure of Mayan civilization may require new interpretations.... The burgeoning reports [of hallucinogenic practices] in recent times suggest that much of the history of the peoples of ancient Middle America will have to be rewritten in light of [material] previously unknown in the psychohistory of these civilizations."



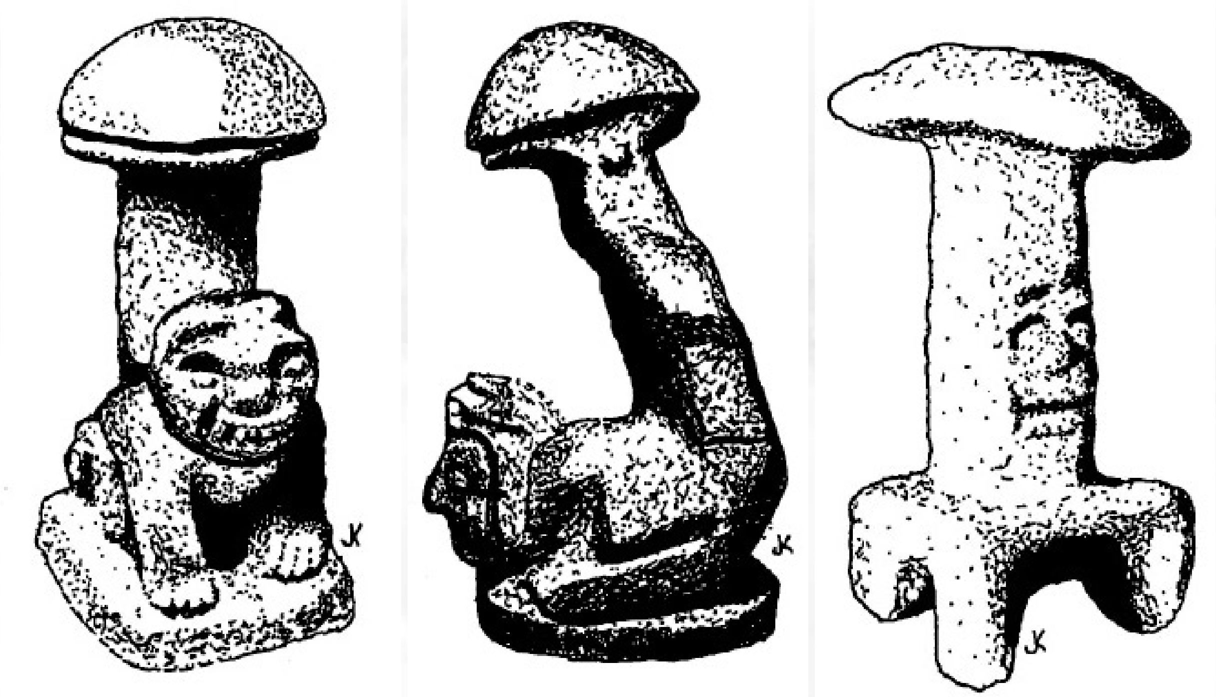
Several problematic variables are dealt with in this article which attest to the model's holistic and heuristic framework of understanding mushroom trade as cultural exchange. One variable is why a demand for different species of the genera *Psilocybe*, *Stropharia*, *Conocybe* and *Panaeolus* (and possibly, *Amanita muscaria*) would have been created by Mayan theologians. A second variable is how ritual and ceremony would have functioned at base organizational levels to manipulate and control sociopolitical and magi co-religious power. Another variable is how mushrooms, like any desired commodity in ancient Mayan society, would have formed the basis for part of (or would have been incorporated into) an already existing trade network connecting the great and small ceremonial centers of the day. A final variable is how well or satisfactorily the physical and ethnographic evidence for mushroom trade meets recent criteria for detecting or inferring its existence in prehistory. The physical criteria relate to Plog's (1977) crucial variables for documenting the existence of trade in the archaeologic record.[1] The ethnographic criteria are discussed in the following section.

The argument ascribes paramount importance to mushrooms in liturgical and curing/divining ceremonies. The viability of trading these sacred ritual artifacts is in documenting their *importance* as supreme power/prestige denominators. The approach of documenting the important place in culture of *magic* mushrooms is necessary.

Unlike concordant attitudes on jade, obsidian, salt and polychrome vessels (ceremonial and utilitarian items accepted by knowledgeable people as performing useful social and economic functions in Mayan culture), some archaeologists, particularly Köhler (1976), maintain that prehistoric Mayas and other peoples did not religiously and supernaturally worship the notorious fungi in ceremonials. Thus, to dispute and eschew Köhler's reasoning is in the model's best interest.

Mushrooms as magical and sacred plants

Millennia ago, a significant climatic change occurred and a postglacial wave of balmy temperatures regenerated new forms of animals and plants over the planet. The bountiful Americas offered human populations drifting down from Berengia (Late Pleistocene/Early Holocene land bridge linking Asia and North America) hundreds of plants to eat. The knowledge of which herbs were esculent and which were foul-tasting and poisonous probably was acquired during a trial-and-error period of indiscreet plant consumption. Questing for new and renewable food sources, nomadic gatherers foraged for plants that sometimes caused illness, sometimes nourished and sometimes killed (Emboden 1979: XIV). A few of the plants induced in users perceptual distortions so bizarre and bewildering (and probably pleasant) that they were at once exalted as "power" plants and as vehicles of transubstantiation. These strange plants - from barks and flower tops to fungi and cacti - assumed a socioreligious status (Furst 1976: 15) that escalated in importance as religious concepts and power hierarchies became increasingly complex.



After Schultes & Hofmann 1979: 148-149.

The archaeologic evidence for ritual mushroom use in Middle America is geographically distributed from El Salvador and Guatemala, westward to Mexico and up to the Gulf Coast. Temporally, they range from Preclassic (Formative) through Late Classic times (Mayer 1977: 19-30; Parsons 1974: 170). Furst (1976: 77) writes that "as long as 3,000 years ago at least the inhabitants of the highlands and the Pacific slope of Guatemala, as well as some of their neighbors, held certain mushrooms to be so sacred and powerful - perhaps even divine - that they represented them in great numbers in sculptured stone." When some of these odd sculptures were first discovered by Kidder, Jennings and Shook in a tomb at Kaminaljuyú, outside of modern Guatemala City, hardly anyone thought to associate the delicate Preclassic lapidary objects with the awareness-altering mushrooms which abound in Guatemala and Mexico.[2] "Due to ignorance of their actual employment and significance," the stones have been variously interpreted as "idols, fertility symbols, phalli, moon gods, cosmos symbols, maize pestles, clay models, field markers for ball games and farming, stone tools and representations of temples" (Mayer 1977: 5). Only the interpretation of their significance as field markers holds water. Their phallic symbolism is clearly flaccid because: (1) genitalia portrayal in other Mayan art forms is abnormal (Why the concentration of erotica at Kaminaljuyú and not elsewhere?); (2) they are one-sidedly male centered (Furst

1976: 80), which is contradictory to the general Mesoamerican trend of dualistic expression; and (3) they were found in association with *manos* and *metates*, for pulverization purposes, and not in association with sculptured vaginas or some other archetypical symbol of fecundity. No explanation sufficed for Kidder and his cohorts (1946) when the stones were brought to light as "peculiar and as yet unexplained objects." Eventually, the works of Wasson (1978, 1971, 1967) and de Borhegyi (1963, 1961) revised anthropological thought on this matter by unequivocally relating the stones in ceremonial symbolism to psychotropic mushrooms. Quite possibly, the carved objects were associated with the Mayan pantheon of night and underworld gods (de Borhegyi 1961).

Two scholars have critically questioned the cogency and reliability of Wasson's and de Borhegyi's work. Köhler (1976) rejoined: "On what do the foundations of their interpretations rest?" He propounds a theory of practicality rather than ceremonialism; linking the sculptured stones to potters' molds. Apparently heedless of their uncanny surface resemblance to psychodysleptic mushrooms, Köhler bases his conclusions primarily on the disparity of artistic styles in the stones (see figures). Why are some fancy and decorated, while the majority are plain and mundane? Because of a preponderance of *practical* stones rather than *ritual* ones, which are effigiated and decorated, Köhler (1976: 146) argues that "there are no indications whatsoever that the mushroom has become a god in its own right." In Köhler's view, mushrooms were probably frivolous and unimportant in Mayan society, and only a few maverick priests may have dared to try them. Richard M. Rose (cited in Mayer 1977: 1) shares Köhler's pragmatic views. In a preliminary report in 1977, Rose stated that the mushroom stones functioned as "effigies of ball players and/or deities of the ball game... as forms used in the manufacture of the rubber balls used in the game." Although these interpretations may aspire to validity, refusal to recognize the stones as mushroom idols "is likely to be a function of R.G. Wasson's ingenious division of people with those who loathe mushrooms and those who like them" (Furst 1976: 80). Schultes and Hofmann (1979: 151) affirm that "whatever the use of these 'mushroom stones,' they indicate the great antiquity of a sophisticated sacred use of hallucinogenic mushrooms."

Besides archaeologic evidence of carved mushroom stones, proto-Classic mushroom pottery and numerous stylizations of narcotic plants on bas-reliefs and monuments in association with deity figures (Emboden 1979: xiv), extant ethnographic parallels also refute the "negative evidence." Ethnographic parallels are useful tools of insight in understanding spiritual constructs of prehistoric peoples. Many groups remain documented case studies of unchanged cultural belief systems involving socially approved drug use to transcend daily life and to contact spiritual and supernatural worlds.[3] La Barre (1970: 120) attributes atavistic rites flourishing in remote parts of Mexico as being "probably the closest extant to the pre-Columbian Mexican rite." Furst (1976: 75-81), Emboden (1979: 90) and Schultes and Hofmann (1979: 153) allude to mushroom rituals among Choi and Lacandon Maya peoples - supposedly in seclusion in temples at Yaxchilan and probably other inaccessible ruins. They concede that formal ethnographic verifications would imply origins of preconquest ritual, not modern introductions or diffusions from elsewhere in historic times. Furst (1972: x) goes on to say that "the present day custom may well have its origins in Classic or Post-Classic Maya ritual," although in a later publication (1974: 59-60) he amended the restriction that one cannot maintain such a view with certainty.

The evidence for the ritual use of mushrooms in ancient times exists in archaeologic and ethnographic contexts. Although it may be subject to various interpretations, a deeper contention of the model acknowledges the cross-cultural and transtemporal importance of sacred alkaloid-rich plants. The Maya were not unique in their devotion and utilization of drugs as media of interpersonal and supernatural experience. In the following sections, sociopolitical and magico-religious parameters of pre-Columbian ritual mushroom use are defined and discussed in the context of trade.

Mushrooms as exploitable plants

Sanctioned drug use as a means of achieving extraordinary mind spaces and prestigious status in the culture might well explain some of the architectural, scientific, spiritual, epistemologic, artistic and political "aberrations" of the ancient Maya. Groping for answers, Furst (1972: x) wrote: "Perhaps, as Coe suggests, the artist-priests of Palenque itself found inspiration for their magnificent creations in mushroom-induced supernatural visions."

The *cult* of the mushrooms might have led to the development of interaction that better exploited the many rapidly perishable mushrooms in the mountains, forests and deer pastures of Mesoamerica.[4] Trafficking in psychotropic mushrooms, though, was an activity of little economic benefit to the Mayan people. As with trafficking quetzal bird (*Pharomachrus mocinno*) feathers and jade, for instance, only certain people *needed* the product. The importation-exportation syndrome of exotic and local products is the crux of the "Core Area - Buffer Zone Model" which Rathje developed in the 1970's to account for the emergence of tropical lowland Maya civilization. Rathje (1972: 386) proposes that Maya civilization evolved "in response to the need for consistent procurement and distribution of nonlocal basic resources useful to every household." Networks sprang up and interaction took place. The networks required regulation and maintenance. A breed of crafty managers and keen organizers arose to direct the trafficking and dispensing of vital salt, obsidian and igneous stone (mushroom effigies are made chiefly out of igneous stone). Rathje believes the procurement and distribution of essential requirements of life ignited Mayan cultural evolution in the jungles of southern Mexico, Guatemala, Belize and Honduras.

When applying Rathje's model to the procurement and distribution of psychotropic mushrooms, disparities emerge on two levels: (1) mushrooms were not the raison d'etre of Mayan culture (then again, neither were jade or brilliant trogon plumage); and (2) an underlying premise of the Transcendental Interaction Model (suggested by Dobkin de Rios [1976, 1974] and by Dobkin de Rios & Smith [1976]) is that "every household" did not have access to ceremonial plants. An ordinary Mayan family probably had about as much access to sacred mushrooms as an ordinary family today has to a Catholic priest's holy waters. In elemental form, Rathje states that economic interaction (trade) was vital to meet the ancient Maya's subsistence demands, and that this presumed interaction caused Classic civilization to flower.

The point is, mushrooms were not consumed for nourishment nor for anything so basic as physiologic survival and well-being. Wright (1974) makes it clear that other items exist and are traded as symbols of wealth or status and prestige. The procurement and distribution of mushrooms, then, was not motivated by "basic necessity" factors of the kind Rathje proposed, because mushrooms were never in the same category as igneous stone, salt and obsidian. Mushrooms, like other elitist ritual items, and unlike "basic resources useful to every household," were never prerequisites of cultural parturition. Other noneconomic motivations to trade must be discussed.

A subliminal noneconomic motivation to trade mushrooms and/or other psychoactive substances comes from a thought in Andrew Weil's book *The Natural Mind* that applies to Rathje's scheme. Weil's intriguing hypothesis is that psychoactive plants are ingested out of human subconscious urges to alter normal waking perceptions.[5] Weil (1972: 17) argues against economic and sociocultural motivations and conditioning to procure drugs: "The desire to alter consciousness periodically is an innate, normal drive analogous to hunger or the sexual drive." Furst (1976: 7) endorses this as a sound cross-cultural hypothesis, yet cautions that "for the present it must rest on circumstantial evidence."

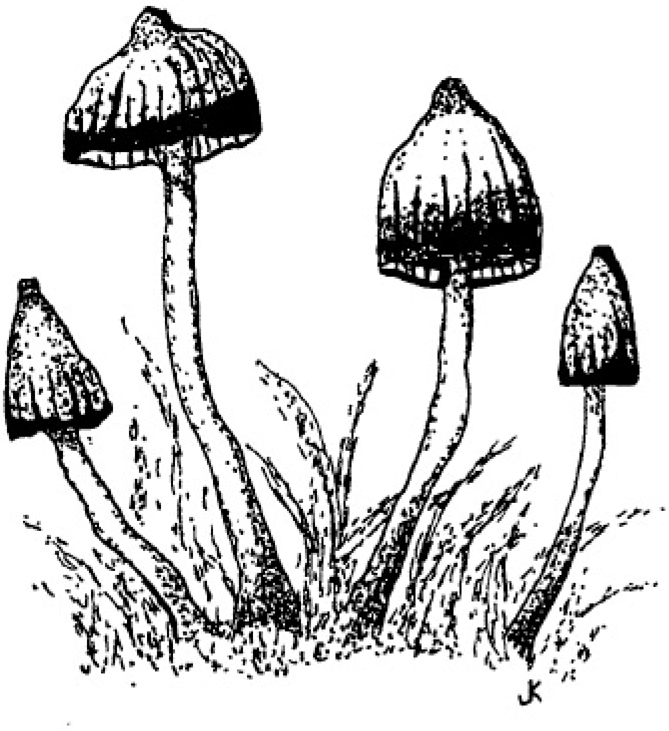
Examining Weil's hypothesis using Rathje's model, the pursuit of mushrooms with specific mind-altering tryptamines can be argued to be an inborn biological drive of the Mayan psyche to satiate certain *basic* psychological (primal) needs; just as the procurement of igneous stone, salt and obsidian was indispensable to the *basic* physical (elemental) needs of a civilization to develop. Although such an argument is highly abstract, Weil's ideas conveniently and logically relate the procurement and utilization of certain local and nonlocal mushrooms (Transcendental Interaction Model) to the procurement and utilization of certain basic resources (Core Area - Buffer Zone Model), in that the procurement and utilization of all four items (salt, stone, obsidian and mushrooms) conceivably can be viewed as an innate response/action to meet requirements of physical and neurophysiologies well-being.

Another noneconomic motivation for trading mushrooms was sheer necessity, born from religious fanaticism and from ritual infatuation which governed vast aspects of quotidian Mayan life. Mushrooms were integral to ceremonies that functioned to contact spirits and seek extramundane knowledge. The plentiful species, valued for different perceptual effects, "acquired a deep and controlling significance in almost every aspect of life" (Schultes 1976: 56). The priests' divinatory enactments, curing ceremonies and other rites geared toward impressing the populace by performing suprahuman feats were ineffectual without transgressing prosaic normal awareness. Potent mushrooms were as indispensable and irreplaceable in certain ceremonies as were choice quetzal bird feathers and priceless jade in others. No ersatz commodities were substituted. If priests could not gain access to suitable ritual mushrooms, other recourses existed for transcendence.

Schultes (1976: 65) comments how different species of mushrooms are utilized owing to "personal preferences" or to a specific "purpose of the use." Schultes and Hofmann (1979: 147-148) also assert that seasonal and regional availability influence choice of mushroom. True, these writers are not discussing trade and economics, but their ethnobotanical statements, per se, do support the possibilities of organized exchange to meet the supplies and demands of personal preferences, specific purposes, and seasonal and regional availability. What does personal preference relate to if not to the tremendous selection in Mesoamerica of psilocin- and psilocybin-containing mushrooms which produce quite different physical, emotional and psychopharmacologic responses.[6] In other words, in the field, one may not expect to find the same assortment of species employed at one time because different mushrooms grow in different places, and also because priests and shamans desired *variation*. Alternative states of perception appealed to priests and shamans who performed different symbolic roles in society; such as healing, predicting eclipses and divining weather for crops, looking into the past and future, and communicating with the gods and spirits.

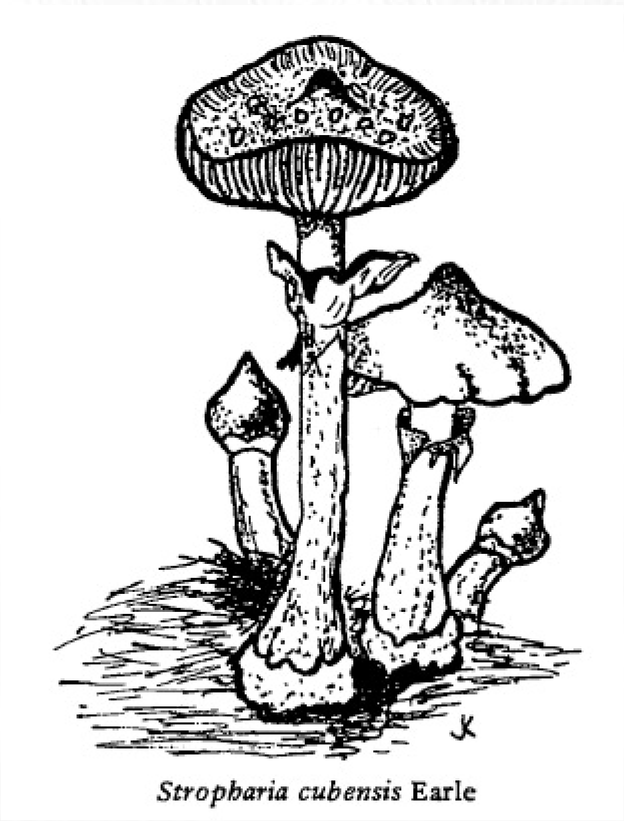
Another question is, how would the priests' choice of mushroom be decided; and why would one species be valued over another; and is it even true to assume that priests would have used diverse species? According to Schultes and Hofmann (1979: 52), modern-day shamans certainly enjoy variation: "Its use [*Panaeolus sphinctrinus*] by Oaxacan Indians along with so many other mushroom species demonstrates the tendency among shamans to use a surprisingly wide range of different mushrooms." An ethnobotanical look at the fungi is worthwhile.

Psilocybe mexicana and *Stropharia cubensis* are two of the most coveted mushrooms in Mexico. Presumably, their spores of popularity germinated in prehistoric eras. The effects of *S. cubensis* are stronger. Between four to eight mg of its juice incite phrenetic gesticulations and afford brilliant, phantasmagoric images quite in contrast to the gentle, subtle and lucid visual undulations of *Psilocybe mexicana* (e.g., Furst 1976: 87). *S. cubensis* possibly, was a likely candidate for the priest interested in utterly transcending mundane surroundings to achieve instantaneous, perhaps mindless godhead. *Psilocybe mexicana*, on the other hand, was possibly reserved for less demanding ceremonies and enactments, where intense overpowering hallucinations, poor motor control and jumbled thinking would have impeded a rational and discerning equilibrium.



Psilocybe mexicana

Psilocybe mexicana
After Schultes & Hofmann 1979: 144-145.

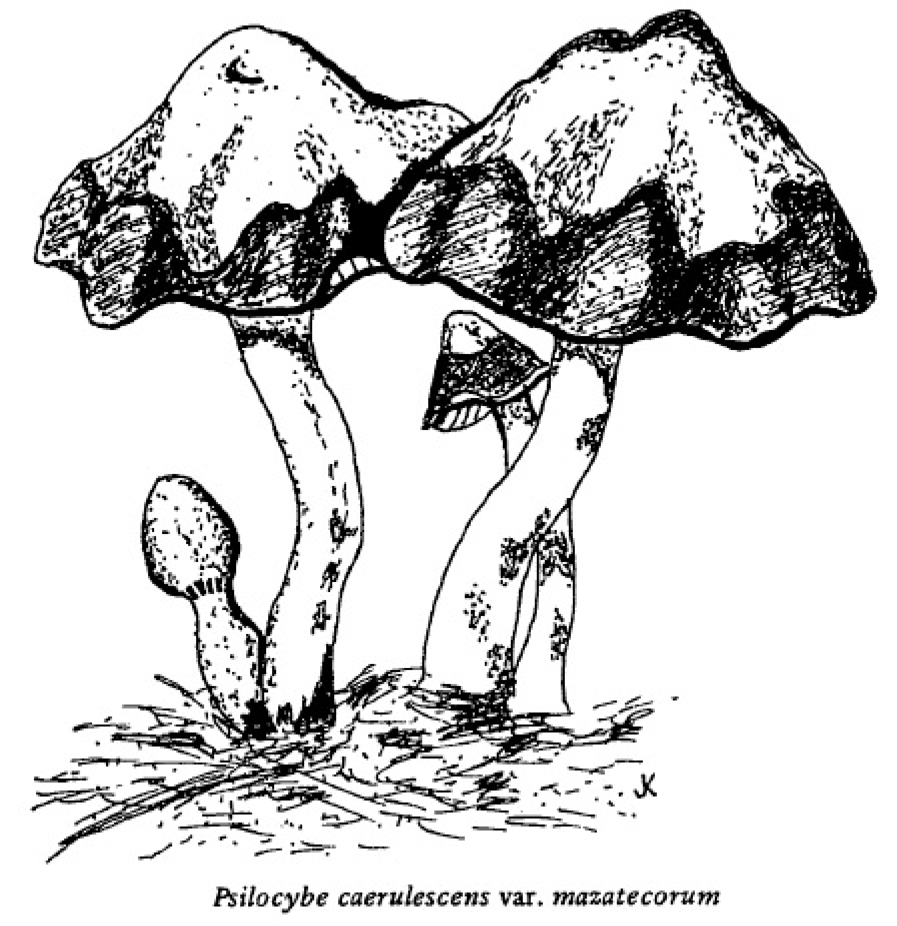


Stropharia cubensis Earle
After Schultes & Hofmann 1979: 144-145.

Stropharia cubensis and *Psilocybe mexicana* are but two of at least 24 botanically categorized and chemically studied hallucinogenic mushrooms exploited in Mexico alone (Schultes & Hofmann 1979: 27).[7] Native names are often indicative of apperceived inherent powers and qualities (Schultes 1976: 65). Etymologies may be traced to pre-Cortes times. *Psilocybe caerulenscens* var. *nigripes* has as a mythological epithet, "mushroom of superior reason." Could it be that this name came about as a result of this particular mushroom's reputation for imparting insightful, intellectual visions? Priests who predicted the future or studied metaphysical relationships between celestial bodies and human existence - arcane tasks demanding accuracy and convincing results - might logically have turned to *nigripes* for superior reason. Other examples of names suggesting idiosyncratic preferences include: *Psilocybe aztecorum*, "children of the waters"; *Psilocybe zapotecorum*, "crown of thorns" mushroom; and *Psilocybe semperviva* the "always alive" mushroom for the ever-active priest. Dated sixteenth and seventeenth century Quiche and Cakchiquel dictionaries also are a source of etymologic clues relating psychedelic fungi to prehistoric culture. The Quiche word *xibalbaj okox* means "mushroom of the underworld" - the nether kingdom where dwelt the Nine Lords as described in the sacred Popol Vuh of the Quiche Maya (Furst 1976: 79).

Was the ritual of mushroom ingestion widespread at a folk level? If so, the idea of everyone having access to unlimited quantities of mushrooms conflicts with and contradicts the idea of mushrooms as controlled commodities in limited access contexts. Perhaps incipiently, folk peoples utilized sacred fungi to facilitate and enhance supernatural contacts, but through time, as seen in Aztec imperial society, divine plants were usurped "for priests, nobility, and special guests of the empire" (Dobkin de Rios 1976: 41). With mushrooms abounding everywhere, a priestly litany of respect and fear kept the average person from picking them; so ultimately they could be used by specialists for "distinctive social goals" (Dobkin de Rios 1976: 41).

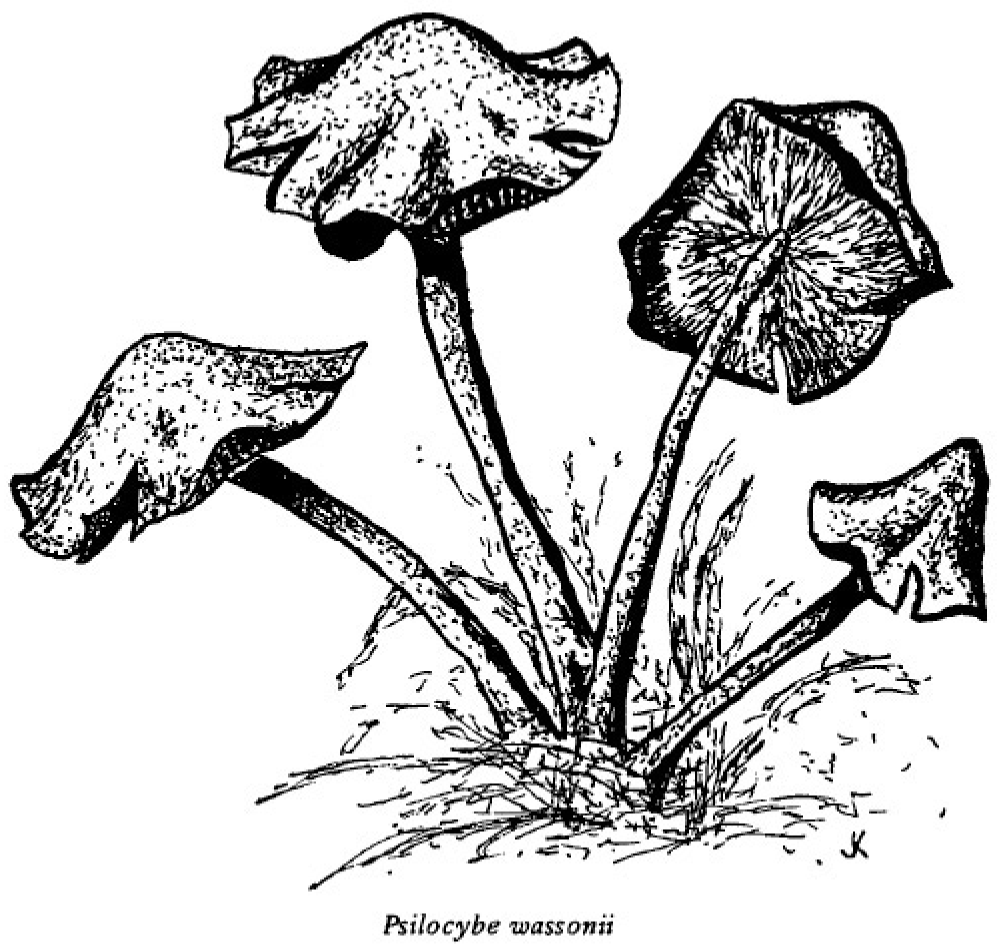
A final question is, what would be the purpose of organizing mushroom procurement and distribution into a regulated network with many sociopolitical and religious ramifications? An overriding motivation to trade mushrooms in a noneconomic context undoubtedly lies in limited access to various species of mushrooms. This implies an abundant product of nature, constantly in demand but not always available fresh, and controlled by elites for the purpose of maintaining them in power. Although Dobkin de Rios (1974: 162) admits she quite possibly overstated her case, in a tightly regulated and controlled trade network her insights into mushrooms being "usurped by hieratic functionaries" (1974: 151) to maintain "legitimate power" are intriguing and make logical, legitimate sense.



Psilocybe caerulescens var. *mazatecorum*
After Schultes & Hofmann 1979: 144-145.

The priest with sacred plant power at his disposal could leave the mundane world, communicate with gods and spirits, fight demons and malefactors, and report back to his people unharmed and tenfold wiser. Such a personage would command utmost awe and respect. He would be a demigod, an interloper between mortals and deities. The prestige and power awarded to mushroomeating hierophants in Mayan society were status indicators of their commitments to perpetuate cultural traditions, maintain social values and ideals, and to seek *beyond* to unravel existential secrets. Only someone in a position of representing the people, however (someone like a high priest who was near totalitarian in power and influence), could experience the visions and contact the deific forces residing in the plants. Dobkin de Rios and Smith (1976: 264-265) remark: "Psychotropic plants ... are denied to commoners ... access to the plants became part of a reward system ... the Maya restricted psychoactive flora ... restrictions of drug use helped maintain the elite in power." Furst (1974: 154), on the other hand, rebukes this notion: "There is no evidence for a 'usurpation' of any of the hallucinogens employed in Mesoamerica by a priestly elite." Furst is right: there is no evidence for it, but there is also no evidence against it, save for Furst's words. Certainly, there were pleasure-god seekers who ingested mushrooms clandestinely, against the Sacred Order of Mushroom Awareness, but the vast majority of peasants was not iconoclastic. They must have respected or feared the priests' dicta that mushrooms were sacred repositories of divine power to be left alone at the risk of insanity, poisonous illness, weird and uncontrollable flights of the soul, and even death.[8] It should be remembered how Catholics the world over once faithfully abided by the Pope's decree not to eat meat on Fridays. Like mushrooms in the hills after a rain, meat abounded in supermarkets on Fridays, but no self-respecting Catholic bought it or ate it. Most likely, sacred mushrooms "would be reserved for magico-religious rites and would not become the object of hedonistic bouts of abandon" (Emboden 1979: XIV) by either priests or peasants.

Technically, it might be impossible to *deny* access to what grows wild, but apparently, for a while the peasants did anything their theocratic masters told them to do: witness the corvée erection of temples and courtyards into staggering ceremonial centers; the clearing of the land; the irrigation projects; and the toiling in the fields. It is not far-fetched to imagine priests telling peasants to stay away from sacred mushrooms, and the latter obeying. Furst, though, claims that "not even the police power of the modern state has been able to stop widespread recourse to forbidden substances" (1974: 154). Is one to believe, therefore, that no matter what fiats the theocrats issued, the peasants ate mushrooms? Furst fails to see two main distinctions between police power of the modern state and the politicoreligious power of the Mayan "loose federation of autonomous city states" (Thompson 1966: 97). One distinction is that police power in the modern state is not remotely derived from the powers believed by aboriginal peoples to reside in certain sacred biodynamic plants, and is in no way contingent upon their usurpation or monopoly in order to retain or maintain power.[9] Secondly, Schultes and Hofmann (1979: 61) note a big difference between using "forbidden substances" today and in preindustrial societies where "plants are gifts of the gods, if not the gods themselves. It is obvious that our culture does not view hallucinogenic plants in this light." If our culture did, then perhaps tighter restrictions and controls would be placed on the use of such potentially power-laden artifacts.



Psilocybe wassonii
After Schultes & Hofmann 1979: 144-145.

The priest who ingested sacred plants became one with the spirit in them. Transforming into an entity dedicated to reifying culture, not escaping from it (Furst 1976: 16), priests had little problem bringing peasants under their tow of politico-spiritual persuasion. Priests were seen as honorable, benevolent people worthy of extreme obeisance. Peasants accepted the absolute prestige and ultimate power of their priest-gods.[10] Additionally, the mushroom eater in Mayan society could accrue prestige and wield inordinate power because of the magical endowments of mushrooms. Under the influence of *Psilocybe mexicana*, *Psilocybe hoogshagenii*, *Stropharia cubensis* or any number of potentially psychoactive fungi, priests could generate enormous power and respect in their roles. They could stage spectacular events for the peasantry, who could consequently only regard their theocratic leaders as suprahuman individuals on whom they bestowed rare apotheosis.

Psychoactive mushrooms were potent instruments of transubstantiation in Mayan religion and ritual. They were social mechanisms for gaining power and accruing prestige, and they also served as "holy mediators between man and his gods" (Schultes 1976: 7).

Mushrooms as local and nonlocal items of trade

Thus far, the desired magical and sacred qualities of species of four genera of psychoactive mushrooms have been discussed in social and politico-religious contexts. Also, some noneconomic, infrastructural functional motivations for trading these various species have been discussed. Furthermore, the psychopharmacologic significance of hallucinogenic mushrooms vis-à-vis certain social imports has been underscored to show how such imports (power, status, honorability and prestige) resulted from exclusive indulgence in the plants, as well as to show how a trade network perforce would have evolved to meet supplies and demands for *variable* altered states of consciousness desired by Mayan priests. The accruement of social imports in trade situations falls under the rubric of "emulation" and complements this author's idea of trade, in that it "brings exotic prestige artifacts which confer status on those individuals controlling the supply" (Renfrew 1975: 33).

The ritual use and importance of hallucinogenic mushrooms, a fundamental premise of the Transcendental Interaction Model, was more extensive and intensive in prehistory than in modern times. It should be remembered what the conquistadors did on learning of the "despised and feared form of plant life." In zealous campaigns of conversion and witch hunting, they forced shamans devoted to divine inebriants to conduct their pagan rites in the hinterlands. A few "refugee" peoples have managed to employ the sacramental plant up to the present day, but the ubiquity and fanaticism of the "mycophobic" Spaniards proved too overwhelming for most of the drug using, persecuted Indians. As Schultes and Hofmann, Mayer, and Furst have noted, at least from 24 to perhaps 57 different species are sought after in postconquest Mexico for important rituals. Was even more variation available before the cultural eradications of 1521 through the present?

Presuming the most ideal conditions of a world view structured on the visions of hallucinogenic mushrooms, one envisions, in ancient times, a desired commodity with variably acting psychoactive alkaloids existing in dispersed abundance. These countless species of mushrooms were in as much demand among priests as was new and shiny obsidian among toolmakers, and rare, bedazzling plumage among elitist artisans. There was no shortage of variation either: the mushrooms' individualized psychopharmacologic natures made them nonhomogenous products; ergo, *exotic* to priests in different regions. Different species do occur at different places; from dead tree trunks and wet pasturelands to marshlands and decaying plant material (Emboden 1979: 89). These various, sporadically appearing mushrooms with their variable powers of perceptual enhancement created demands by priests to partake of more than just their few locally occurring varieties, which were limited as ritual, transcendent paraphernalia. Perhaps dozens of psilocin- and psilocybin-containing mushrooms existed and were used by the Maya and other peoples. Perhaps they still exist and have yet to be discovered.[11] Schultes and Hofmann (1979: 148) are optimistic about this: "The probability that more species will be found in use is far from remote." The number of species in use before 1521 might have been phenomenal.

Is it foolhardy to think of priestly elites trading back and forth this revered "plant of the gods"? Local and long distance trade of revered artifacts is evident in early cultures of Mesoamerica. Thin orange pottery from Monte Albán and Teotihuacán is found at Kaminaljuyú; glazed plumbate wares with Mexican deities occur commonly at Maya components; salt was brought in from afar; and renowned eccentric flints, which perhaps originated in Guerrero or western Mexico. Dobkin de Rios (1974: 148) conjectures that "trade in psychotropic substances may have occurred" in contiguous areas.

Further convincing evidence for the trading of revered hallucinogenic artifacts is found in the appearance of an anthropormorphic gold "Darien pectoral" from Panama or Colombia at Chichén Itzá in Yucatán. Schultes and Bright (1979) arrive at the "inescapable conclusion" that these curious objects (over 150 exist in the Museo del Oro in Bogotá) represent the "religious use in prehispanic Colombia of intoxicating mushrooms." According to these two authors, and a number of other scholars, hallucinogenic mushrooms figured prominently in magico-religious rituals of aboriginal peoples all over the New World, including as far north as Canada and as far south as the Andes of Peru. Gold mushroom effigy pectorals, such as the one found at Chichén Itzá, along with mushroom stones, clay artifacts and stylizations on pottery were most probably items of long-distance exchange among members of prehistoric hallucinogenic-using cultures where artifacts were revered by shamans and priests as objects of deific, magico-religious devotion to mushroom spirits. The potential of real psychotropic fungi having made similar long-distance trips as items of exchange cannot be down-played. The genus *Psilocybe*, valued in Mesoamerica for species-variable psychoactive experiences, is also abundant in lower Central America and Colombia, with as many as 30 species reported (Schultes & Bright 1979: 121). Quite possibly dozens of species of *Psilocybe* mushrooms were traded back and forth throughout the ancient Americas.

If the question is still, "Why trade mushrooms?"; then, one ought to now presume the most inauspicious conditions and circumstances in ancient times *against* setting up a trade system to procure and distribute desired variations of hallucinogenic mushrooms. Could not Mayan priests simply pick the local fungi they wanted at the moment? And then, would not a handful of local varieties satisfy demands for different hallucinatory (spiritual) experiences? The quality of local fungi probably did not meet demands for *variable altered states*, since many different kinds of mushrooms were needed; depending on current states of mind, types and purposes of ceremonies, and seasonal and regional availabilities. Furthermore, Mayan priests probably were not likely to go mushroom foraging in the wilderness. Other people, minions and devotees of the priests, collected and traded mushrooms as psychoactive variations of a desired transcendent state. Mushrooms were traded locally and even as far away, perhaps, as central and western Mexico and southern Central America.

Long-distance exchange of hallucinogenic plants is entirely plausible, as demonstrated by the diffusion of peyote cacti (*Lophophora williamsii*) "far beyond the natural range of the plant into the United States and Canada, where Indians receive 'mescal buttons' by purchase from native Americans residing in Texas" (Schultes & Hofmann 1979: 134). Another contemporary line of evidence for ancient roots in the trade of psychoactive substances in Guatemala was supplied by mycologist B. Lowy (1977: 124), who reported that a local trade of psilocybin mushrooms was flourishing. Children were harvesting the fungi and were "offering them for sale to a clientele who traveled considerable distances to make their purchases."

Does the question, "Why trade mushrooms?" still exist? Why engage in formal exchange when so many species abounded? The following is a list of some of the known hallucinogenic mushrooms found in Mexico and Guatemala:

Psilocybe acutissima
Psilocybe aztecorum
Psilocybe caerulescens var. *mazatecorum, nigripes, albida, ombrophila*
Psilocybe cordispora
Psilocybe fagicola
Psilocybe hoogshagenii
Psilocybe mexicana
Psilocybe mixaeensis
Psilocybe semperviva
Psilocybe wassonii
Psilocybe muliercula
Psilocybe yungensis
Psilocybe zapotecorum var. *elongata*
Psilocybe candidipes
Psilocybe caerulipes var. *gastonii*
Psilocybe isauri
Conocybe siligineoides
Stropharia cubensis
Panaeolus sphinctrinus
Panaeolus fimicola
Amanita muscaria

Besides these, other nonhallucinogenic mushrooms existed and were ritually consumed for divinatory purposes owing to peculiar, suggestive shapes; among them, *Cordyceps capitata*, *Elapbomyces granulatus*, *Dietyophora phalloidea* and two others, *Clavaria truncata* and *Nevrophyllum floccosum* (always in association with *Psilocybe wassonii* [Wasson 1978: 82]). And what of the many poisonous varieties which are capable of altering awareness? Weil (1980: 47) asserts that one can select over a wide range of toxicity and derive pleasurable and satisfying visionary experiences. This opens up a virtually infinite supply of mushrooms and a demand for their variable alternative states.

The big question - the grand test of the viability of this reasoning - is whether or not all the mushrooms listed above occur locally and in equal distribution. If they do, then so much for local and nonlocal exchange of psychoactive mushrooms in the Transcendental Interaction Model. Schultes and Hofmann (1979: 147) point out, however, that it is just the opposite: "There may be years when one or more species are rare or absent - they vary in their distribution and are not ubiquitous." For example, there is definite limited access, intraregionally, to the species *Psilocybe aztecorum* and *Psilocybe mexicana*. The former grow only on the volcano, Mt. Popocatepetl; and the latter grow only above altitudes of 1,375 to 1,675 m (Schultes & Hofmann 1979: 151).[12] Limited access to these and other mushrooms, including local varieties, provided a rationalization to devise an exchange system managed by elitist priests and their cohorts involving the transfer and flow of the commodity among priests of all areas of Mesoamerica. Stone carvings indicate that some individuals, possibly traders, were at Kaminaljuyú. Who is to say what they might have brought with them and were taking back to Teotihuacán and elsewhere? Polanyi's (1975: 136) criteria of trade, which must involve personnel, goods, carrying and two-sidedness, are met sufficiently in the context of ancient Mayas and other contiguous culture groups reciprocally exchanging psychotropic mushrooms.

Mushroom exchange must be seen as intensive and intraregional. However, the idea of *local exchange* of mushrooms, which this author advocates along with distant exchange, conflicts with Rathje's idea of trade in a rainforest environment, in which he claims that all local exchange would be absent because of "ecological redundancy." This may hold true for most products exploited in a redundant milieu, where no need or exigency arises to trade them, but hallucinogenic mushrooms were exchanged locally and distantly because they were not a redundant product. Their individual protean visionary powers were avidly prized by priests.

If mushrooms were available locally, Polanyi's (1975: 136) definition of trade as a "method of acquiring goods that are not available on the spot" conflicts with a basic premise of the Transcendental Interaction Model. Mushrooms were available "on the spot" for the Maya, but mushrooms of one area may have afforded different visual experiences from those of a contiguous area; or some from a land beyond may have been desired because they affected motor movements and coordination; while others which might have occurred in a ubiquitous habitat may not have even been available owing to rainfall variations, perhaps, or to a decrease in the local deer population and the necessary excrement on which certain species grow. For these reasons, as well as the individual preferences of Mayan holy men, the supply in one area did not necessarily meet the demands of that area.

Renfrew's Law of Monotonic Decrement (1977: 85) states that some places "will receive less of a commodity than its neighbors nearer to the source." This is true in the context of the Transcendental Interaction Model, only in as much as it was a variation of a specific commodity and not the commodity itself which decreased in frequency the farther one got away from the source of a desired species of mushroom for a particular enactment. In other words, all priests had access to mushrooms (the commodity), but the desired variation of the commodity may sometimes have been absent or disproportionate because of distance, weather, idiosyncratic preferences and other related factors. Trading for goods that are not available on the spot (for example, different species of variably acting mushrooms) would evolve logically and inevitably into an activity of extensive/intensive transference of a commodity in demand because of desired variations in visionary experience. Dobkin de Rios (1976: 73), citing R. Blum, notes that the "more complex the society the more [one] can anticipate internal variety in drug use." Schultes and Hofmann (1979: 52) indicate the variation that shamans and priests desired.

According to Polanyi (1975: 144), the basis of procurement depends on the exigency of the products as functional and desired items in society; and also on the "difficulty of acquiring and transporting" the products. What sorts of problems, if any, might Mayan harvesters and traders have encountered in acquiring and transporting a rapidly perishable product like psilocybin mushrooms? Would they still be valued in a state of putrefaction? If serving rotten and foul-smelling mushrooms on the altar/platter of a ritual enactment was blasphemous, no priest would have settled for anything but fine mushrooms. But if mushrooms pop up and die as ephemeral creations of nature, how could supplies and demands possibly have been met?

Agaricaceae and Strophariaceae plants do not have to be immediately transported or consumed. They may instead be preserved; and ingestion of a dried form was common. The *manos* and *metates* found in conjunction with mushroom stones, together with certain mural depictions and wide-ranging ethnographic parallels, all suggest this. Artificial dessication, however, has a tendency to alter the taste and potency of the product.

Freshly picked mushrooms yield a psilocin and psilocybin content of about 0.03% of total weight, while dried specimens have a more concentrated 0.3% of the psychoactive principles (Schultes & Hofmann 1979: 23), since the weight of water and other organic matter evaporates. Although the alkaloids in mushrooms appear not to be water soluble, the amount of psilocin and psilocybin in fresh and dried mushrooms is not constant. Generally, the drier the specimen, the less potent it is. If many priests were using dried material, they would have needed regular and reliable access to more mushrooms than required when eaten fresh. If the percentages above *are* somewhat constant, dried mushrooms still might have been preferable since the bulk weight of ingestion would be reduced ten times. The alternate state of consciousness induced by dried specimens still was highly valued by priests looking for the "overall desirable qualities" mushrooms afforded. Also, by drying the product and preserving it for later dissemination, supplies could be met in areas where certain mushrooms were out of season, exceedingly rare or nonexistent.

The mushroom trade model conforms to Polanyi's view of trade: goods were available and obtainable locally and nonlocally; they were exploitable on the spot, in several hours or days later; and the only discernible defects in the product were altered taste and reduced potency. The reduced potency, however, implies a scarcity of a more powerful variable product, and therefore a staging ground for an ideal market in which large supplies of *ritual brand* dried mushrooms were exchanged.

Mushrooms as culturally integrative pharmacopoeia

The Transcendental Interaction Model derives cogency and unity from supporting research and comments by numerous scholars pursuing eclectic information.[13] The documentation by botanists, chemists, anthropologists, medical doctors, archaeologists and mycologists of the importance of hallucinogenic mushrooms in preliterate societies affords comfortable margins in extrapolating their pervasive role in prehistory.[3] A contingent argument of the model is that ritual/hallucinogenic/transcendent/curative and other ceremonies were much more pervasive and important in autochthonous cultural tradition before the arrival of Europeans in the early sixteenth century; and considering the zealous and phobic way the Spaniards set about denouncing and expunging hallucinogenic practices among Middle American cultures 450 years ago, it is astonishing that any practices at all involving transcendental ritual have survived the inquisitorial centuries.

Up to now, the model has been mainly concerned with noneconomic reasons for the reciprocality of exchanging variable fresh and preserved supplies of *necessary* hallucinogenic mushrooms. It is important now to consider plausible mechanisms and systems of the hypothetical mushroom exchange network. What was its structure? What groups or people traded and controlled mushrooms and toward what social, political and religious ends? How did mushroom trade figure in to an overall cultural matrix of events and relationships? The focus of the first part of this section is on reciprocity.

Many ritual artifacts were reciprocally traded by the ancient Maya, and the subliminal implications of this particular *style* of trade for the elites of society who made it work, enhance the idea of mushroom exchange. Wright's (1974) statement that "trade facilitates the exchange of ideas as well as of material commodities," synthesizes quite nicely the point that no matter how important sacred mushrooms were as material ritual items, they were equally important as sources of new ideas, insight and cultural input. Mushrooms may have been de facto items of exchange, but that aspect was only half the purpose - the overt half of what was being traded. Acquiring mushrooms and trading them locally and nonlocally created social bonds, or an interaction sphere wherein thoughts could be shared, information relayed and friendly relations stabilized.

Using Sahlins's (1972: 194) threefold classification scheme, a "balanced" system of reciprocal mushroom exchange wins out over "negative" and "generalized" systems (and over any other mode of substance exchange) because balanced reciprocity "refers to direct exchange." Additionally, Sahlins (1972: 195) believes that direct exchanges are socially and economically advantageous because they "stipulate returns of commensurate worth or utility."[14] Thus, Party A, dealing in mushrooms, might not have reciprocally received from Party B the equivalent in psychoactive material, even though Party A might have been in the market for a variation of that necessity. Direct exchanges, then, might have involved mushrooms for jade, quetzal bird feathers or aesthetic polychrome wares, since these and other commodities in ancient Mayan society represented exotic ritual returns of commensurate worth and utility. In one way or another, status, prestige and power were derived from or were affiliated with each item mentioned above.

Sahlins points out the relative unimportance of the actual trade item by stressing the importance of egalitarianism in trade. When trade takes place as an "equitable exchange of different necessities" (Sahlins 1972: 220), the result is social harmony and well-being. Hallucinogenic fungi as items of exchange in prehistoric Mayan society may have played a role in structuring relationships. If five sacks of *Psilocybe yungensis* were traded for two sacks of *Stropharia cubensis*, or if three lapidary objects of exquisite jadeite were traded for a beautiful *eccentric* flint, it would be egalitarian reciprocity. Now, what if Party A attempted to upset the harmonious balance of exchange by offering inferior mushrooms for superior ones, or fool's jade for the finest obsidian blades? Would not relations among groups of people become soured and disrupted by *inequitable* exchanges of different necessities? The procurement and distribution of essentials often leads to conflict in exploiting and trading them. Consider, for example, the possibility of a shortage of mushrooms, for whatever reason. If religious and political power went hand in hand, as they did in the defunct theocratic civilization, imagine the ramifications if priests in certain areas were deprived of locally occurring varieties of hallucinogenic mushrooms - the all-important artifacts of power and prestige. Or, better yet, imagine the ramifications if priests - certain disliked, recreant ones - were *purposely* deprived of locally *and* nonlocally occurring mushrooms by a power coalition of elitist priests. Is politico-religious dependence so far-fetched? Although no single Mayan site is believed to have been more powerful or influential than another, Culbert (1974: 74) demonstrates the existence toward Late Classic times of regional states. Bird Jaguar and Jeweled Skull were two powerful leaders who vied for politico-religious prominence. Can the satellite relationships between certain smaller and larger ceremonial centers, and between some Mayan centers and distant cultures like Teotihuacán or Monte Albán, be interpreted as politico-religious dependence? Or, at least, can it be politico-religious control owing to asymmetry of resource flow?

Trade as balanced reciprocity gave Mayan priests an inexhaustible supply of dried and fresh mushrooms from all over Mesoamerica.[15] In idealized form, balanced reciprocity always ensured a continual flow and influx of essential, desirable commodities. Concomitantly, and perhaps more importantly, ideas were exchanged and relations among the politically polarized but culturally knit Maya (Weaver 1972: 154) were affirmed and enhanced.

Mushrooms as ethnobotanical reality

The Transcendental Interaction Model is viable because it is in harmony with what knowledge is available on contemporary and extinct societies, early trade patterns and presumed politico-religious importance of hallucinogenic substances in ancient cultures. Verifying the existence of exchange systems in prehistory is, for the most part, like trying to verify or divine something in the future. In either respect, clues and data are often nonexistent. Although it is permissible to concoct situations and theories which logically and conveniently meet Plog's (1977) most demanding conditions for verifying trade, hard physical evidence is lacking for a more rigorous analysis and therefore a more scientific treatment of his criteria.

The commodity of trade discussed in this article is a perishable one. So were textiles in most early cultures, and definitely in Mayan culture. But who is to say if they were or were not traded? Ritual mushroom worship has survived the ages only in the form of happenstance discoveries of sculptured stones and pictographic representations on walls and codices. There are historical chronicles relating the use and importance of psychoactive plants in preconquest cultures, bequeathed to Western knowledge by Spanish friars and Jesuits who reviled their deific powers as paganism, idolatry and insanity. There are also elusive and ambiguous ethnographic descriptions of some Mayan peoples in Chiapas conducting rites with hallucinogenic mushrooms, but no one has concretely documented the veracity of these reports from the 1970's. Otherwise, nothing relevant to paleomycologic studies exists. The trade analyst working with jade, obsidian or pottery at least has a modicum of the actual item exchanged, and thereby can run chemical characterizations and study it in precise detail to determine exact origins and learn more fully its functions and ritual nature. This cannot be done with centuries-old commodities that have been ritually consumed and only infrequently memorialized in stone, painted murals and in latter-day vestiges of preliterate ceremonials.

Besides serving as agents promoting social worth, value and respect of tradition, hallucinogenic plants have always figured in mystico-religious quests for power and knowledge in human cultures around the world. For millennia, they have been exploited, utilized and worshipped for their amazing properties to alter reality and create access to worlds beyond: to the "wilderness of mind," where one is able to "celebrate or contact the realm of the supernatural, to heal an illness, diagnose its cause, divine the future or to promote social solidarity ..." (Dobkin de Rios 1976: 73).

The Transcendental Interaction Model's primary contribution to ethnobotanical knowledge has been to place exploitation, utilization and worship of psychoactive mushrooms in a specific context. This trade model does not impute any etiologic significance in the rise and fall of Classic Mayan civilization. Rathje's hypothesis of procurement and distribution of essential daily requirements and what might occur in cases of massive deprivation is insightful and could be a correct assessment of what caused Mayan civilization to flower, and conversely, what effected its downfall.

In a class with several other psychoactive florae employed ceremonially by ancient priests and shamans in Mesoamerica, mushrooms assumed an integral role in the infrastructural continuity of Mayan religion and ritual; and not in the macrostructural continuation of Mayan civilization. A culture absolutely dependent on psychopharmacologic substances for its well-being and survival is extremely anomalous. No drug has ever been so all-important as to actually create or destroy a culture. No culture in recorded human history has ever been dependent on drugs for basic survival, even though a huge pharmacopoeia pervades all levels of ritual and traditional life.

Dobkin de Rios (1974: 162) remarks: "I do not wish to suggest that we can reduce all of Maya culture to a series of drug-induced input." For certain, this is not the point of her work in the field; nor is it the point of the Transcendental Interaction Model. Hallucinogenic mushroom consumption was only an aspect of a vast mosaic of drug and nondrug ritual activities of the Maya. Of course, it is folly to think of these aboriginal people as perpetually intoxicated on narcotic plants, and to attribute all creations and innovations in art and technology to their recondite powers. Still, because of profound drug use and abuse in modern society, it is unwise to lose sight of the importance and respect that sacred plants assumed in ancient societies.

The intention of this article has been to highlight a specific context in which ritual hallucinogenic mushroom procurement, utilization and worship can be placed in ancient Mayan society. For some, it may come as a welcome attempt to structure the use of mushrooms into a contextual framework and to deal in depth with a subject in Mayan ethnology whose importance has been underplayed too long. For others, years may pass before the Transcendental Interaction Model is firmly rooted in the ethnobotanical reality espoused by growing ranks of serious mycophiles.

Acknowledgments

The author would like to thank Marie E. Ceccanese for her input of ideas and wealth of humanistic anthropological common sense, and especially for her patience, support and courage; Oscar Chamberlain for his editorial skills and heuristic sensibilities; Dr. Haree Deutchman for legitimizing and endorsing the initial research proposal at Indiana University in the spring of 1979; Professor Marlene Dobkin de Rios for her contributions and refinements; Jan Kearney for her beautiful pen and ink renditions of mushrooms and mushroom stones; and R.C. Rosenbalm for an unremitting interest in the project.

Notes

1. Plog's "particular characteristics" cannot be avoided in a discussion of trade in ancient times. Besides not varying with investigative problems, "it is unlikely an investigator can accurately model exchange networks without attention to the characteristics" (Plog 1977: 129-130). Since Plog's approach is a technical aspect of the trade model, which mainly interests archaeologists, a specialized discussion of his variables as related to psychoactive mushrooms is not in order here. In any event, in archaeologic trade records - be the item of trade pottery, stone or jade - Plog's (1977: 128) query about "What should one try to learn of the organization of this network?" is difficult, if not impossible, to answer. Unless all the variables are satisfactorily accounted for, the documentation of trade should be presented as only a logical and viable extrapolation of conceivable events in prehistory.
2. Mayer (1977) blatantly contradicts himself on pages 3 and 5 by first saying that mycologist Bernard Lowy (1977) found *Psilocybe mexicana* in Guatemala, and then claiming an "apparent absence" and also that "none of these exist in Guatemala." Köhler (1976) is another who seems to believe that

psychoactive mushrooms are not found in Guatemala. A consensus of experts cited in the references of this article indicates otherwise.

3. No matter how traditional in application ethnographic analogies may be, they never directly reflect bygone cultural activity. To reconstruct past civilizations accurately, all data are needed: not merely a sprinkling of artifacts and ecofacts; not primarily epigraphic attempts to decipher baffling stone inscriptions; not chiefly ruined ceremonial centers and ancient middens and sumptuary tombs, but every minute datum. All the data are never amassable in any field or project, but the few data that are available provide for logical inferences and viable extrapolations or constructions (also, divinations [Thomas 1974]). Construction of possible mushroom connections does not connote the specious accuracy of detail and truth that *reconstruction* does, which should be dismissed as an archaeologic misnomer.
4. Peter T. Furst (1976: 172-173) speculates that certain species of mushrooms which grow only in cow manure in modern Mexico, and therefore unavailable in prebovine America, might have flourished anyway in the dung of another ruminant, the deer, which figured prominently in Amerindian aboriginal peoples' symbolic and mythopoeic concepts of nature and *nagual* animism. Furst connects the sixteenth century prohibition by Mazatecs against the killing of deer (and the meaning of their name, "People of the Deer") to an "easily observable relationship between deer and their [Mazatec] preferred sacred psychoactive mushroom."
5. Dr. Weil hastens to add that while reality altering is a desired, worthy and socially approved means of exploring beyond mundane consciousness, it can be achieved with or without the aid of psychoactive plants and animals. If trade routes were severed and all hierophants were suddenly deprived of consistent supplies of hallucinogenic mushrooms for ritual enactments, an absence or paucity of the commodity probably would have had little social and economic repercussion; for numerous recourses to altered states of reality existed. A disrupted trade network might just signal the end of a mushroom connection. Yet, with other trade items (for example, Rathje's basic necessities of salt, igneous stone and obsidian) an absence or paucity of the commodity might well have resulted in a calamitous breakdown of systems.
6. Set and setting (individual moods, cultural contexts, societal expectations and milieu) certainly modify the pharmacologic effects of a given substance in a particular ambience (Weil 1980: 3), notwithstanding different chemical reactions in the brain and central nervous system. It would be highly speculative to talk about perceptual alterations on a chemical level, but having diligently experimented with several species in varying dosages, and in identical and removed environments with and without the same people (both Western and non-Western), this author feels that at a subjective level it is safe to conclude that the central excitation of his nervous system was qualitatively altered under the influence of different and identical species of hallucinogenic mushrooms. That is, each psychoactive experience was found to be, for example, more intense, or less colorful, or more stupefying, or less physically demanding, or more insightful than another. Marijuana serves as a phytochemical parallel, even though it is a nonalkaloid plant. The two main species, *Cannabis sativa* and *C. indica* definitely exert different energies on the mind and body, owing to their varying concentrations of tetrahydrocannabinol (THC). Similarly, hallucinogenic mushrooms have different potency levels which affect psychoactivity. The indolic alkaloid content responsible for changes in brain chemistry varies from species to species between 0.2% and 0.6%, and less in dried specimens (Schultes & Hofmann 1979: 79). The auditory, visual, physical and gustatory effects achieved when one species is substituted for another are quite different in intensity and potency. This is the variation hierophants desired. Moreover, the differences in intensity and potency are noticeable even within identical species. Emboden (1979: 162; italics added) supports this view: "The psychopharmacology of mind-altering plants is so complex that *a single plant may have multiphasic effects* due to its chemistry or according to dosage."
7. Mayer (1977: 34) states that 35 different species of hallucinogenic mushrooms are registered in Mexico, yet he offers no taxonomic verification of their existence or provenience. Furst (1976) refers to an astonishing 57 species utilized, but offers no listing, either.
8. If priestly propaganda had peasants believing that insanity and death were the prices to be exacted for the recreational use of hallucinogenic mushrooms, how did the "usurping hieratic functionaries" get away with their copious indulgences of the fungi? The answer lies in *ritual*: transcendent ceremonial enactments staged and orchestrated by powerful elitist Mayan theologians. In this standardized set and setting context, Weil (1980: 57) notes that "ritual and ceremony work to minimize the potential of drugs to cause negative experiences."

9. Although police power is not derived from sacred psychoactive plants, consider a form of usurpation, monopoly and control in modern society of certain legal medicinals, crops (e.g., the growing and sale of hops) and drugs (caffeine, nicotine, alcohol, barbiturates, amphetamines, etc.) by conglomerate tobacco and alcohol industries and pharmaceutical companies. The tight controls and restrictions by big business and government serve the pecuniary interests of these elite medical and pharmaceutical professions: their wealth perpetuates power, and ultimately, corruption.
10. Did the *downtrodden* and *oppressed* peasants - forever dimly spotlighted against the flashy backdrop of Classic Maya culture - ever finally tire of their situation and rebel? Possibly toward Late Classic times, a period of decadence, corruption and infighting, masses of hungry and angry peasants were mobilized into insurrection. Popular campaigns against established orders in the process of decay and disintegration hardly ever fail, as witnessed again and again in historical parallels. If peasant Mayan farmers and slaves could have united under a leader in a front against their perceived elite oppressors, their undermining and sabotaging tactics, along with other deleterious events, might have contributed to a full-scale toppling of Mayan civilization.
11. Spotting the fruiting bodies of camouflaged fungi in native habitats is a tricky enterprise (Weil 1980: 60,77). If the model of mushroom trade is correct, perhaps experienced and reverent individuals were called on who developed a knack for finding and collecting wild specimens. Perhaps a breed of special, ritual harvesters existed in Mayan social structure to disclose the whereabouts - the econiches - of exotic, potent species of mushrooms. Perhaps a group akin to the elite *Pochteca* trader class of Aztec society existed. It is probable that the *Pochteca* handled all transferences of the northern desert peyote cactus; for Dobkin de Rios (1976: 36) states that "it was dried and transported several hundred miles to the south," to Aztec territory. Could a Mayan *Pochteca* have collected and distributed mushrooms all over Mesoamerica?
12. Lowy (1977: 124) has botanically identified *Psilocybe mexicana* as occurring in Guatemala. Previously known only in Mexico, the discovery of this agaric in southern Mesoamerica raises some questions. Has *Psilocybe mexicana* always grown locally in Guatemala? If so, its appearance to Western eyes after all these years demonstrates the lacuna in ethnobotanical lore. Or, were spores of *Psilocybe mexicana* introduced into Guatemala ages ago by traders from Mexico?
13. It should be emphasized that none of these scholars had as a research proposal the documentation of mushroom exchange networks in ancient Mesoamerica. The notion probably never even entered their minds, but their comments about related matters - personal preferences, seasonal and regional availabilities, chemical compositions, residential deities with power-giving qualities and hieratic usurpation of controlled substances - indirectly supported certain claims and premises of the Transcendental Interaction Model. This author does not feel that he has misrepresented words or taken ideas out of context, but rather, has formed an interpretation based on sound inferences and logical extrapolations.
14. It is possible that many trade items were purchased using cacao beans (genus *Theobroma*) as currency. Sacred mushrooms, though, might have been in a league by themselves. Schultes and Hofmann (1979: 148) report that in present-day Oaxaca, mushrooms are not sold in marketplaces, although it is possible that they are reciprocally exchanged. Contradictory to this, Lowy (1977: 124) reports observing mushrooms for sale. Presumed reciprocal exchange among the ancient Maya might have taken place in a secluded temple or perhaps in the privacy of a special off-limits place. In any case, mushrooms were not necessarily traded expressly for mushrooms.
15. If obliged to present *negative* evidence against mushroom exchange in prehistoric Mesoamerica, a basic question arises: Why were the Maya never attracted to peyote (genus *Lophophora*) or morning glories (genera *Turbina* and *Ipomoea*) for ritual enhancements? Aztec wizards combined and alternated a multiplicity of mind-altering plants in ceremonies, including the revered *Teonanacatl*, the mushroom "flesh of the gods." To argue that the cacti were nonlocal, remote commodities (hence, not available for procurement and distribution) is fruitless if the Transcendental Interaction Model has presented a faithful context of long-distance exchange of psychoactive plants. The Maya most likely knew about peyote from lore coming out of western and central Mexico, but evidently they were content with mushrooms and the amazing variety they offered. Besides, it is not as though the Maya restricted themselves to one drug. They also utilized the probably psychoactive water lily (genus *Nymphaea*), which is seen repeatedly in art motifs; and there is evidence that bufotenine from the common toad contributed to the psychoactive pharmacopoeia employed by the ancient Maya in rites and sacraments (Dobkin de Rios 1976: 45).

I

Because of the important roles which they played in ceremonial and in daily life, the narcotic plants of ancient Mexico are of especial interest to the anthropologist. Mexico possessed and still possesses many plant narcotics and intoxicants, of which a few are outstanding in their uses and are extremely interesting because of their great antiquity as well as because of the important bearing their use, distribution and history may have on questions of a theoretical nature. Of the most notable, are the *toleselo* or *coral-berry* (*Sophora secundiflora* (Ort.) Lag. ex DC.), *ololiuhqui* or *piule* (Rivea corymbosa (L.) Hall. f.), *peyote* (*Lophophora williamsii* (Lem.) Coult.), and *teonanácatl* (*Paneolus campanulatus* L. var. *sphinctrinus* (Fr.) Bresadola).

Long the center of confusion and ambiguity, *teonanácatl* was not known botanically until very recently. Therefore, a thorough discussion of the ethnobotanical history of this narcotic mushroom should be made available to anthropologists in order that the erroneous interpretations now rather widespread in anthropological literature concerning *teonanácatl* may be corrected.

II

In his *Historia de las cosas de Nueva España*, Sahagun[2] recorded the earliest description of *teonanácatl* and discussed its narcotic and medicinal uses among the Mexican Indians of the period of the Spanish conquest. One of these references in a general consideration of useful plants, states that they (the Chichimecas) possessed a great knowledge of plants and roots, and they were acquainted with properties and virtues of them; these same people were first to discover and use the root which they called *peiotl*, and those who are accustomed to eat and drink them used them in place of wine; and they did the same with those which they call *nanacatl*, which are harmful mushrooms which intoxicate in the same way as wine...[3]

A more detailed description of the plant and its uses occurs in a chapter which deals specifically with narcotic plants:

> There are some small mushrooms in that region which are called *teonanácatl*; these grow under the grass (hay) of the fields and pastures. They are round, have a rather high stipe, slender and terete. When eaten, they have a bad taste, hurting the throat, and they cause intoxication. They are medicinal for few fevers and for rheumatism. Only two or three need to be eaten. Those who eat them see visions and feel a faintness of the heart. And they provoke to lust those who eat a number, or even a few, of them.

From Sahagun's reports (as well as from other early reports which are quoted below), it is absolutely clear that the narcotic which the Aztecs called *teonanácatl* was a mushroom. *Teonanácatl* has been identified with the dried tops of the peyote-cactus, *Lophophora williamsii* (mescal buttons) and this misidentification has been widely accepted in botanical and anthropological literature. For this reason, it is necessary to examine closely and evaluate all of the early reports concerning *teonanácatl* and its uses. In the first of the excerpts quoted above, Sahagun clearly distinguished between "the root which they call *peiotl*" and "*nanacatl*, which are harmful mushrooms." Likewise, in the chapter on plant narcotics, from which the second excerpt is taken, Sahagun discusses, in one paragraph, the "small mushrooms ... which are called *teonanácatl*" and, in another paragraph *peiotl*, the "earth-cactus."

There is another herb like the earth-tunas which is called *peiotl*. It is white and grows in the north. Those who eat it see terrifying and amusing visions. The intoxication persists for two or three days and then stops...

Still further assurance that *teonanácatl* was a fungus is found in a third reference to the narcotic in Sahagun's *Historia*:

> The first thing which they ate at the gathering was small, black mushrooms which they called *nanacatl*. These are intoxicating and cause visions to be seen and even provoke sensuousness. They ate these (mushrooms) before dawn, and they also drank chocolate before daylight. They ate these little mushrooms with honey and when they began to be excited by them, they began to dance, some singing, others weeping, for they were already intoxicated by the mushrooms. Some did not want to sing but sat down in their quarters and remained there as if in a meditative mood. Some saw themselves dying in a vision and wept, others saw themselves being eaten by a wild beast; others imagined that they were capturing prisoners in battle, that they were rich; that they possessed many slaves, that they had committed adultery and were to have their heads crushed for the offense, that they were guilty of a theft for which they were to be killed, and many other visions which they saw. When the intoxication from the little mushrooms had passed, they talked over among themselves the visions which they had seen.

In a chapter on mushrooms (*De las setas*), Sahagun used the term *nanacatl* to refer to mushrooms:

> The cone-shaped mushrooms (*nanacatl*) *genus campos agrorum* in the mountains are good to eat. They are cooked for this purpose...

Sahagun not only described *teonanácatl* as a mushroom, but the plant is figured in (Plate CI; Fig. 453a) the *Paso y Troncoso* edition of Sahagun's writings as a small mushroom growing in a grassy field.

In addition to Sahagun's direct statements that *teonanácatl* was a mushroom it is obvious from linguistic evidence that the term *nanacatl* refers to mushroom. *Teonanácatl* probably was the specific word for the intoxicating mushrooms, for it appears that *nanacatl* referred to mushrooms in general. In Mexico at the present time, mushrooms are called *nanacates*.

In his *Dictionnaire de la langue Nahuatl ou Mexicaine* Siméon analyzed general words which include the root *nanacatl* and clearly indicated the meaning of the term:

> *Nanacatl*, Champignon: *quauhtla-nanacatl*, champignon des bois; au. fig. *nanacatl nicte-ittitinemi* (Olm.), rendre quelqu'un pervers, lui donner de mauvais conseils. En comp.: *nonanac* ou *nonanacauh* (Olm.) mon champignon, R. *nacatl*?
>
> *Nacatl*, Chair, viande; ... nonac, ma viande, la chair que je mange.
>
> *Teonanácatl*, Espèce de petit champignon qui a mauvais goût, enivre, et cause des hallucinations; il est médicinal contre les fièvres et la goutte (Sah.) RR. *teotl*, *nanacatl*.
>
> *Teyhuinti*, Qui enivre quelqu'un, enivrant; *teyhuinti nanacatl*, champignon enivrant.

Further evidence can be derived from a definition of *teonanácatl* offered by Jourdanet and Siméon in their translation of Sahagun's *Historia*:

> (*Teonanácatl*) c'est a dire: champignon dangéreux. La terme générique est *nanacatl*, qui se met en composition avec d'autres mots pour designer les diverses espèces de champignons.

As further corroboration, the compounds used by Hernandez may be cited. By adding adjectival prefixes to a modification of the term *nanacatl*, Hernandez[4] described several types of mushrooms under the heading "*De nanacatl seu Fungorum genere*": *iztacnanacame* (white mushroom), *tlapalnanacame* (reddish mushroom), and *chimalnanacame* (yellow-orbicular mushroom). He described *teonanácatl* as *teyhuinti* or "intoxicating."

In his *Catálogo*, Garcida[5] called eleven species of *Agaricus*, one of *Hypophillum*, and two species of *Boletus*, all Oaxacan *Fungi*, by the common name *nanacatl*. This is certainly convincing evidence that the word still refers to mushrooms in modern Mexico.

In the works of Serna,[6] a very complete description of the use of "coloured mushrooms," *quatlannamacatl* as a narcotic for divination is found:

> And it so happened that an Indian had come ... bringing some of the coloured mushrooms which are gathered in the hills and, with these, he had performed a great idolatry. But before explaining this (idolatry) I wish to explain the nature of the said mushrooms which, in the Mexican language, are called *quatlannamacatl* ... these mushrooms were small and yellowish and to collect them, the priests and all men, appointed as ministers for these impostures, went to the hills and remained almost the whole night in sermonizing and in superstitious praying. At dawn, when a certain little breeze which they know began to blow, they would gather them (the mushrooms), attributing to them deity. They have the same effect as ololiuqui and peyote, for when they are eaten or drunk, they intoxicate, depriving those who partake of them of their senses and making them believe a thousand absurdities.

A further description of the use of narcotic mushrooms, *teunamacatlth*, is given by Benvento in Kingsborough[7] and by Orozco y Berra:[8]

> They had another kind of intoxication... which was induced by small toad-stools or mushrooms... which are eaten raw. Because of the bitter taste of these mushrooms, they drink after them or eat with them a little honey after which they shortly see a thousand visions, especially snakes. They went raving mad, and they ran about the streets wildly ... In their language they called these mushrooms *teunamacatlth*, a word which means "bread of the gods"...

The meaning of the word *teonanácatl* has been questioned recently by LaBarre,[9] who states that Benvento's etymology ("bread of the gods") is wrong. The acceptance of this etymology or a similar one ("flesh of the gods") is wide. Safford[10] accepted "flesh of the gods" as a correct translation of *teonanácatl*. Bancroft,[11] furthermore, writing of Nahuatl intoxicants, said:

> Among the ingredients used to make their drinks more intoxicating the most powerful was the *teonanácatl*, "flesh of the gods," a kind of mushroom which excited the passions and caused the partaker to see snakes and divers other visions.

In an unpublished manuscript,[12] V. A. Reko applies the meaning of "divine food of a soft or fleshy nature" to *teonanácatl*. According to usage reported to Siméon,[13] *nanacatl* refers to mushrooms in general, but Siméon suggests, with reservations, that the root of *nanacatl* may be *nacatl*, the word for "meat" or "flesh." According to Siméon, therefore, *teonanácatl* may mean "flash of the gods."

In early Mexican literature, other references to the uses of mushrooms for intoxication are less detailed but nevertheless of interest and of importance.[14] Usually, they lack common names or descriptions which might make it possible to identify the actual plant which was used.

Kingsborough reports that "wild mushrooms" were given to visitors to Montezuma's coronation, and that the mushrooms intoxicated the visitors and caused them to dance.[15]

Motolinia[16] described a religious feast held by Montezuma at which intoxicating wild mushrooms were eaten; the visions which accompanied the intoxication were believed to constitute divine advice concerning the future.

Duran, quoted by Bourke,[17] states that, after the sacrifices of human beings at the coronation of Montezuma II, the multitude ate raw mushrooms which induced an intoxication which was much stronger than alcoholic intoxication; many committed suicide at the height of the intoxication, some received visions and were, in this way, enabled to prophesy the future. Although it is difficult to identify the plant which served as the narcotic these cases, the symptoms of the intoxications induced are the same as those induced by the *teonanácatl* of the ancient Aztecs and are the symptoms of the intoxication induced only (among the mushrooms) by membbers of the genus *Paneolus*, the genus with which *teonanácatl* has been identified.

Thompson[18] reports Saville as saying that Tizoc, an Aztec ruler, who was poisoned after a five year reign, may have been killed by the substitution of poisonous mushrooms for the intoxicating kinds which were normally eaten at ceremonies. The deadly *Amanita phalloides* (Fr.) Quél. may possibly have been the instrument of death, but this species never could have been secretly substituted, in a fresh condition especially, for the entirely different *Paneolus* spp., while slightly poisonous, they are not known to cause sudden death by poisoning.

III

The many references to the general use of narcotic mushrooms among Mexican Indians of four hundred years ago suggests to the ethnobotanists of the present time that these plants may still be used in parts of Mexico, in a similar way.

Curiously enough, the actual utilization of mushrooms as intoxicants in modern Mexico was unobserved until very recently. In 1923, Doctor Blas Pablo Reko wrote, in a letter to Doctor J. N. Rose of the United States National Herbarium,[19] that the *teonanácatl* is a "fungus ... which is still used under the same old name by the Indians of the Sierra Juárez in Oaxaca in their religious feasts."

In 1936, Mr. Robert J. Weitlaner of Mexico City visited the capital of the Mazatec region of Oaxaca, Huautla de Jiménez, and learned of the use of certain mushrooms in witchcraft and divination among these primitive peoples. He secured a few samples of the narcotic plants and sent them to Reko who forwarded several pieces to the Botanical Museum of Harvard University for identification.[20] These specimens were insufficiently preserved upon arrival to make possible a definite specific identification; they belonged to the genus *Paneolus*, and were possibly referable to a species which is closely allied to *Paneolus campanulatus* var. *sphinctrinus*.

While I was engaged in ethnobotanical investigations among the little known Mazatec Indians of the District of Teotitlán, Oaxaca, with Dr. B. P. Reko in the summer of 1938, samples of the narcotic mushrooms and information concerning their use were collected in Huautla de Jiménez.[21] These mushrooms are referable to *Paneolus campanulatus* L., var. *sphinctrinus* (Fries) Bresadola.[22] Though apparently used rather frequently, the plant does not appear to be common in the Mazatec country. It is valued highly. Growing in boggy pots in pastures and open fields it as easily available only during the rainy season from June to September. Those who search for, the plant gather and dry the specimens for use during the rest of the year. Because of the belief that the mushroom is semi-sacred, it is not offered for sale in the markets of the Mazatec towns, although the yashun paper (made from the bark of *Heliocarpus appendiculatus* Turcz.) and other articles for *brujería* (witchcraft) are important articles of sale in the markets of Huautla.

The native Mazatec names by which *Paneolus campanulatus* var. *sphinctrinus* is known in Huautla de Jiménez and San Antonio Eloxochitlán are *t-ha-na-sa* (meaning unknown), *sheto* ("pasture mushroom"), and *to-shka* ("intoxicating mushroom").

Among the Mazatec Indians there are professional divinators who earn a livelihood locating stolen property, discovering secrets, and giving advice through *Paneolus*-intoxication. It is impossible to state whether or not these divinators practice their art exclusively with *Paneolus*; it is probable that they are general *curanderos* (herb-doctors) as well. Due probably to the frequent ingestion of the slightly poisonous *Paneolus*, they are said to age rapidly, signs of approaching senility being apparent at the age of thirty-five.

The narcotic is taken to induce a semi-conscious state which is accompanied by a mild delirium. The incoherent utterances which are made during the intoxication are interpreted as prophetic or admonitory.[23] The doses which the Mazatec Indians prescribe vary with the size and the age of the individual. Usually fifteen mushrooms are considered sufficient to induce the desired effect, but larger doses are reported. Overdoses of fifty to sixty mushrooms result in severe poisonings, while continued use of excessive quantities is said to produce permanent insanity. While this might be an unexpected physiological result of the type of intoxication induced by species of *Paneolus*, it was not possible to verify this with actual cases in the field. According to a number of descriptions from the Indians, the intoxication lasts about three hours. Shortly after ingestion of the mushrooms, the subject experiences a general feeling of levity and well-being. This exhilaration is followed within an hour by hilarity, incoherent talking, uncontrolled emotional outbursts, and, in the later stages of intoxication by fantastic visions in brilliant colours, similar to the visions so often reported for the narcotic peyote (*Lophophora williamsii*).

Johnson,[24] engaged in ethnological work among the Mazatec Indians in 1938, was informed that *brujos* (witch-doctors) use several kinds of mushrooms. He reports the names of these as *steyi* and *tsami-ye*, *tsamikishu*, and *tsamikindi*. Unfortunately it was not possible to procure specimens, photographs, or descriptions, and botanical identification is thus precluded. It is not improbable, however, that one or more of these is a *Paneolus*. Although in my two visits to the Mazatec country narcotic mushrooms other than *Paneolus campanulatus* var. *sphinctrinus* were not found in use in divination, it is possible that poisonous mushrooms of the same or of other genera may be utilized. As emphasized below, the intoxication which has symptoms making it valuable to the Indians for divination is especially, but not exclusively, typical of the entire genus *Paneolus*.

Mr. Bernard Bevari of Mexico City, who has carried out ethnological studies among the Chinantec Indians and who has visited the Mazatec tribe, writes in a letter to me, that he was informed of the use of mushrooms for intoxication among the Mazatecs.

Extending my ethnobotanical investigations in northeastern Oaxaca in the spring and summer of 1939, I learned that *Paneolus campanulatus* var. *sphinctrinus* is used as a narcotic for divination among the Western Chinantec Indians. The consumption of the narcotic is not uncommon in the western Chinantla[25] where the fungus grows in the high mountain pastures during the torrential rains of July. In the *pueblitos* of Santa Cruz Tepetotutla and San Pedro Sochiapam in the District of Cuicatlán, aged men were seen gathering this mushroom in fields, and in San Juan Zautla, District of Cuicatlán, information as to the use of the plant was obtained from two sources. In Tepetotutla five mushrooms (Schultes 722) were obtained from one of the gatherers in exchange for several quinine pills. In these Chinantec villages, the *Paneolus* has the name *nañ-tau-ga* the information as to the utilization of the plant and descriptions concerning the intoxication were identical with those obtained from the neighboring Mazatec Indians. Furthermore, in Tepetotutla, I was informed that small doses of from five to eight of these mushrooms are prescribed for several consecutive days for severe attacks of rheumatism. No medical uses were reported in the Mazatec region but, according to Sahagun, *teonanácatl* in small doses of two or three was medicinal for fevers and for rheumatism among the Aztecs.

Further evidence of the use of narcotic mushrooms was obtained among the Chinantec and Zapotec Indians who together inhabit the small town of Latani, near Santiago Choapam, District of Choapam, in the south-easternmost corner of the Chinantec area. Since my visit to Latani was made before the advent of the late June and July rains, it was impossible to collect specimens of the fungus which, according to the inhabitants, is eaten as a narcotic for divination. Very detailed descriptions of the fungus and a full account of the type of intoxication which it induces indicate that the intoxicating mushroom of Latani is also a species of *Paneolus*. The possibility that it is *Paneolus campanulatus* var. *sphinctrinus* is not remote. The Chinantec name is *a-ni* ("medicinal mushroom") or *a-mo-kya* ("medicine for divination").

It is interesting to note here that *ololiuqui* or *piule* (the seeds of *Rivea corymbosa* (L.) hail. f., often mistakenly identified as a *Datura*), another divinatory-narcotic of ancient usage in Mexico, is found growing in dooryards in Latani and is used, in the same way as the mushrooms, as an aid to divination.[26]

There can be little doubt that *Paneolus campanulatus* var. *sphinctrinus* is used among other Indian groups in Oaxaca and possibly in other states as well. Johnson writes in a letter to me that the mushrooms are known to the Cuicatec Indians of the District of Cuicatlán, Oaxaca, but that these people do not use them. Reko has learned by correspondence that the Zapotecs of Santiago Yaveo, District of Choapam, Oaxaca, use this narcotic, but when Reko and I visited this pueblo in 1939, no specimens could be obtained. Search for this use among the Zapotec Indians of Santa Maria Tonaguia, San Ildefonso Villa Alta, Santa Maria Temascalapa, San Juan Yatsona and San Juan Yaée produced no results. Likewise, during a very short stay in the Mije country, I could not learn of its use among the inhabitants of Santa Maria Chisme, San Juan Metlaltepec, and Santiago Zacatepec (at the base of Cerro Zempoaltepetl). I think that it is highly probable that the narcotic properties of the *Paneolus* mushrooms are employed in divination among these peoples, however, and that when intensive investigation is carried out among the Mijes, the use of *Paneolus* will be discovered in this poorly studied tribe.

The names under which *Paneolus campanulatus* var. *sphinctrinus* is or has been known may be summarized as follows:

> Aztecs: *nanacatl* (mushroom); *teonanácatl* (sacred mushroom); *quauhtlananacatl* (wild mushroom); *teunamacatlth* (probably an erroneous rendition of *teonanácatl*).
> Chichimecas: name unknown.
> Chinantecs: *nuñ-tau-ga*; *a-ni*; *a-mo-kya*.
> Mazatecs: *t-ha-nu-sa* (meaning unknown); *she-to* (pasture mushroom); *to-shka* ("intoxicating mushroom"). Although the names for the narcotic mushrooms reported by Johnson cannot definitely be applied to this species, it is probable that the mushrooms are species of *Paneolus*: *steyi*; *tsami-ye*; *tsamikishu*; *tsamikindi*.

IV

Paneolus campanulatus L. var. *sphinctrinus* (Fr.) Bresadola is a small mushroom of boggy spots in meadows during the rainy seasons. This species and its closest relatives are found on all the major continents. The mushroom is about ten centimeters high, with a slender, terete, dark brown stipe from one to two millimeter in diameter. The dark colour of the stipe serves to separate this variety from its close relative, *Paneolus papilionaceus* Fries. The pileus, three centimeters in diameter and one half centimeter high, is either parabolical, conical, or nearly hemispherical, often slightly cuspidate or obtusely acuminate, smooth, light yellowish-brown. The gills are spotted and are dark brownish-black. The spores, varying from 12-18 x 7.5-12 µ, are black, sublimoniform. When dried, the entire mushroom assumes a brownish-black colour.

An excellent coloured illustration of *Paneolus campanulatus* var. *sphinctrinus* is to be found in Bresadola's *Iconographia Mycologica*.[27] Technical Latin diagnoses of the characters of the plant may be found in Bresadola's *Iconographia Mycologica* and in Fries' *Epicrisis*;[28] Bresadola's Latin diagnosis is republished in Schultes' *Plantae Mexicanae II*.

V

Species of the genus *Paneolus* have long been known to be poisonous,[29] but the use of *Paneolus campanulatus* var. *sphinctrinus* as an intoxicant in Mexico is the only instance in which its properties have been employed for narcotization, so far as I have been able to learn from the anthropological and botanical literature.

Ford[30] divides mushroom-poisoning into five categories, according to the physiological action of the poisonous constituents of the plants: 1) the choleriform type (caused by the deadly *Amanita phalloides* (Fr.) Qutl.); 2) the nerve-affecting type which is marked by convulsions, coma, and occasional deaths (caused by *Amanita muscaria* (L.) Pers., which is used in Kamchatka as a narcotic); 3) the gastrointestinal type; 4) the blood-dissolving type; 5) and the cerebral type. Paneolus-intoxication belongs to the fifth category of poisonings. The narcotic action is mainly cerebral and is characterized by exhilaration, a feeling of ease and well-being, muscular incoordination, drowsiness, a staggering gait or difficulty in walking, emotional excesses, laughter and hilarity, incoherent and delirious speech, mydriasis, and fantastically coloured visions.

Most of the full descriptions of the use of *teonanácatl* among the ancient Aztecs indicate, by the peculiar type of intoxication, that the mushroom was a species of *Paneolus*. It is indeed significant that these early descriptions and the notes obtained from the Mazatec, Chinantec, and Zapotec Indians agree completely with the description of a typical *Paneolus*-intoxication by Douglas[31] and Krieger.[32]

Knowing that *Paneolus* was a poisonous genus, the late Professor Santesson[33] carried out a series of pharmacological studies with specimens of *Paneolus campanulatus* var. *sphinctrinus* which were collected in the Mazatec country.[34] The results of experiments with frogs indicated that a principle was present which induced a kind of narcosis very similar to that which is induced by ololiuqui (*Rivea corymbosa* (L.) Hall. f.) another Mexican oracular narcotic. Santesson called this state "eine Art Halbnarkose." Chemical tests convinced Santesson that a glucoside, but no alkaloid, was present. This is rather unexpected, since in

Amanita muscaria (L.) Pers., the Kamchatkan narcotic mushroom, the active principle is an alkaloid-muscarine.

VI

The identity of *teonanácatl* was unknown for three centuries. During this time doubt has been expressed concerning the accuracy of all of the earlier writers in describing the narcotic as a "mushroom." As a result, considerable confusion and uncertainty arose and a serious error has been accepted and widely spread in the botanical and anthropological literature.

The first attempt to identify *teonanácatl* botanically was made in 1915, when Safford[35] published his conclusion that the so-called "mushroom" was, in reality, the dried tops of the cactus *Lophophora williamsii* (Lem.) Coulter and, notwithstanding all of the numerous early reports, was not a fungus. "Three centuries of investigation," wrote Safford, "have failed to reveal an endemic fungus used as an intoxicant in Mexico, nor is such a fungus mentioned either in works on mycology or pharmacography; yet the belief prevails even now that there is a narcotic Mexican fungus ..." On the basis of this argument, Safford concluded that the dried, brown, discoidal head ("mescal button") of the spineless peyote-cactus (*Lophophora williamsii*) resembled a "dried mushroom so remarkably that, at first glance, it will even deceive a mycologist." When this "remarkable" resemblance is analyzed with actual specimens, however, it is found not to exist. There is actually very little similarity in appearance between the dried pilei of *Basidiomycetes* and mescal buttons. The shrivelled crowns of the cactus have a heavy cushion of closely packed areolate tufts of silky hairs on the upper surface and a conspicuous fibrovascular region on the lower surface. It seems highly improbable that either the early writers or the Indians were likely to confuse dried peyote with dried mushrooms. But Safford concluded that those same people who gathered peyote and *teonanácatl* (one of which inhabits dry, calcareous deserts; the other, wet, soggy, mountain pastures) failed to recognize the hard wrinkled, brown mescal-buttons (which Safford stated were *teonanácatl*) as a part of the soft, succulent, green peyote-plant. The former he assumed the Aztecs called *teonanácatl*, the latter, *peiotl*.

Much of Safford's ethnobotanical investigation of Mexican plants was brilliant. It is not surprising, therefore, that his conclusions on this mysterious "narcotic mushroom," which was known only in the literature, were accepted and became firmly established in both botanical[36] and anthropological literature.[37] This identification was repeated several times by Safford and early gained a wide audience.[38] Some of the recent writers on the subject of narcotics, however, have not accepted Safford's conclusions.[39] Prior to 1915, when Safford made his identification of *teonanácatl*, a number of authors had occasion to mention the narcotic and accepted the statements which all of the early writers had made concerning the fact that *teonanácatl* was a mushroom.[40]

The first published objection to Safford's identification appeared in 1936 in a popular book by V. A. Reko[41]: "*Dem* (the Safford identification) *muss widersprochen werden. Die Nanacates sind Giftpilze, die mit Peyote nichts zu tun haben* ..." He suggested, but apparently without any basis, that *nanacatl* might be a species of *Amanita*.

From the first appearance of Safford's identification, however, Dr B. P. Reko has opposed the opinion that *teonanácatl* was a form of peyote. In 1923, he wrote to Dr J. N. Rose of the United States National Herbarium:[42]

> "... I see in your description of *Lophophora* that Dr Safford believes this plant to be the 'teonanácatl' of Sahagun which is surely wrong. It is actually as Sahagun states, a fungus which grows on dung-heaps and which is still used under the same old name by the Indians of the Sierra Juárez in Oaxaca in their religious feasts ..."

In 1919, he had stated[43] that *teonanácatl* was "*div. généros de hongos, especialmente un hongo negro que crece sobre estiercol y produce ejectos narcóticos*."

In 1939, specimens of *Paneolus campanulatus* L. var. *sphinctrinus* (Fr.) Bresadola which were collected in the Mazatec country of northeastern Oaxaca were identified as *teonanácatl*[44]. Later, the same plant was found to be used among the neighbouring Chinantecs and Zapotecs. There is, therefore, no longer any reason for the retention of Safford's misidentification of *teonanácatl* with *Lophophora williamsii*.

The entire genus *Paneolus* is known to be poisonous. Differences between species are often very slight and extremely technical. Different species, having the same intoxicating properties and being so similar in gross appearance, are without doubt utilized along with *Paneolus campanulatus* var. *sphinctrinus*. Although I have found no other mushroom used as *teonanácatl* in Oaxaca, numerous reports that there are several kinds of *teonanácatl* must be interpreted to mean that other species are actually used. Although the identification of "teonanacatl" was made on the basis of specimens of *Paneolus campanulatus* var. *sphinctrinus*, it is probable that this vernacular name refers to several or numerous species of *Paneolus* and that further ethnobotanical research will result in the discovery of other species which serve as divination-narcotics in southern Mexico.

VII

In summary, it may be stated that:

1. *Paneolus campanulatus* L. var. *sphinctrinus* (Fr.) Bresadola (and possibly other species of *Paneolus*) is used as a narcotic in witchcraft and divination among the Chinantecs, Mazatecs, and Zapotecs of southern Mexico.
2. The size, colour, form, growth habits, uses, and narcotic effects of *Paneolus campanulatus* var. *sphinctrinus* correspond so closely to the descriptions of the same aspects of the *teonanácatl* of the Chichimecas and early Aztecs that there can be no doubt that this species represents the intoxicating mushroom which was described by many of the early writers as one of the chief narcotics of Mexico at the time of the Spanish Conquest.
3. The discovery of the use of *Paneolus* in three Mexican Indian tribes and its identification with *teonanácatl* should dispel the confusion which has resulted in the literature from Safford's misidentification of *teonanácatl* with peyote.
4. Although it seems to have been and to be widely used in southern Mexico as a narcotic, *Paneolus* is not known to be utilized as an intoxicant by any other group of primitive peoples.

Notes

1. It is with pleasure that I express my appreciation of the constant interest which Professor Oakes Ames, Director of the Botanical Museum of Harvard University, has shown in the ethnobotanical work which has led among other things, to the rediscovery of *teonanácatl*. I wish also to thank the several workers whom I mention to this article for making available for me unpublished information in their possession.

20. In an earlier article (32, p. 39), I stated that these mushrooms were collected among the Otomis of Puebla. This is an error which was caused by a misunderstanding in correspondence. In the article I gave no credit to Mr. Weitlaner for his work on *teonanácatl* in the Mazatec country, since this information has only recently been communicated to me by Mr. Jean B. Johnson.

22. Schultes (February, 1939).
23. This, interestingly, parallels the use of ololiuqui or piule (*Rivea corymbosa*) which is also used as a narcotic for divination in parts of Oaxaca. Investigation revealed that this narcotic convolvulaceous plant, the seeds of which are used, is known in the Mazatec region but is no longer utilized. It is used, however, by the Chinantec and Zapotec Indians to the south (Schultes ined.).
24. Jean Bassett Johnson (1939).
25. The term *Chinantla* is extremely ambiguous, having been used in a number of different senses by historical anthropological and botanical writers. It is a term which, as Bevan points out (Instituto Panamericano de Geografia e Historia. Publ. N. 24, Mexico, 1938) should be used only in its widest sense: "a synonym for the region where any dialect or Chinantec is spoken". It is used here in this sense.

IV. Summary
BIBLIOGRAPHY

I. Introduction

Investigations dealing with the vegetable narcotics, intoxicants, and poisons used by primitive peoples comprise studies which involve some of the most fundamental culture-traits. The narcotic plants of the New World especially are attracting popular attention while stimulating scientific interest. In this connection, a large ethnobotanical and ethnopharmacological literature is being developed. A recent anthropological study (13) has briefly summarized some of the information concerning the primitive uses of a number of narcotics and has emphasized the importance to theoretical anthropology of correctly identified and thoroughly investigated ethnobotanical material. Indeed, this summary and other recent papers have clearly emphasized the need, as well as the desirability, of further botanical and ethnological investigations of plant narcotics, their uses, and their significance.

The plant narcotics of Mexico are of unique interest because careful records of their uses at the time of the Spanish Conquest are often available. It is possible, therefore, to compare their past uses with the uses made of them at the present time. Fundamental to any study of this kind, however, is a thorough botanical investigation of plant uses among modern Mexican Indians and a critical examination of the earlier ethnobotanical records.

Botanical and anthropological literature contains many references to a mushroom which has been employed as a narcotic by some of the Indians of Mexico. The Aztecs and the Chichimecas were the earliest recorded users of these mushrooms which they called *teonanácatl*. For several centuries, however, the identity of *teonanácatl* has remained obscure. Recurring references to it have mystified biological and anthropological investigators, inasmuch as careful search had failed to reveal any Mexican fungus possessing properties used to induce a narcosis. It has been suggested that the reports which associate *teonanácatl* with a mushroom are misleading or erroneous, although the sources from which they come are in other respects dependable and credible.

Both from a botanical and ethnological point of view a knowledge of the identity of *teonanácatl* should prove of value. Furthermore, the correct identification of this narcotic plant is rendered desirable and necessary because an obvious misidentification has gained wide acceptance among botanists and anthropologists.

II. The identification of teonanácatl

In the summer of 1938, I began ethnobotanical investigations among the Mazatec Indians of northeastern Oaxaca and learned that a mushroom, subsequently identified as *Paneolus campanulatus* L. var. *sphinctrinus* (Fr.) Bresadola[1], was being used as a narcotic.

In 1937, Dr. Bias Pablo Reko, my co-collector in Oaxaca, sent me several pieces of a mushroom which he found used as a narcotic by the Otomi Indians of Puebla and adjacent regions. Unfortunately, these specimens were poorly preserved, but they are referable to the genus *Paneolus* and belong to a related if not to the same species as those which were collected in Oaxaca.

Johnson (9) reports that three kinds of mushrooms are used by Mazatec *brujos* (witch-doctors); the names of these he reports as *steyí* and *tsami-yé*, *tsamikíshu*, and *tsamikindí*. Although botanical identifications were not made, it is probable that these are all species of *Paneolus*, possibly *P. campanulatus* var. *sphinctrinus* and its close allies *P. campanulatus* L. and *P. papilionaceus* Fr.

When identifiable specimens of the fungus had been secured and when ample information regarding its use was obtained, it became evident that *Paneolus campanulatus* var. *sphinctrinus* was the *teonanácatl* of the ancient Aztecs.

Paneolus campanulatus Linnaeus var. *sphinctrinus* (Fries) Bresadola Iconographia Mycologica (1931) t. 894.

Agaricus (Paneolus) sphinctrinus Fries Epicrisis systematis mycologici seu synopsis Hymenomycetum (1836-1838) 235-236.

Bresadola's description is:

> "Pileus carnosulus, parabolicus, obtuse acuminatus, opacus, levis, udus, glaber, fuligineo-nigricans, sicco olivaceo-lividus vel fuligineus, subsericeus, 1½-2½ cm. altus latusque, velo albo primitus dentato-appendiculatus; lamellae subconfertae, postice adnatae, cinereo-nigricantes, atro-maculatae, acie concolores; stipes fistulosus, cylindraceo-filiformis, aequalis, fuligineo-griseus, apice albopruinosus, deorsum rufescens, basi albo-floccosus, 5-8 cm. longus, l½-2½ mm. crassus; caro tenuis, dilute umbrina, inodora et insapora; sporae sublimoniformes, fusco-atrae, opacae, leves, 14-18 - 9-12µ; basidia clavato-capitata, 25-30 - 12 - 14µ; cellulae aciei lamellarum cylindraceae, 50-60 - 6-7µ."

MEXICO: in boggy spots in meadows during heavy rains, Huautla de Jiménez, Oaxaca, July 27, 1938, *Richard Evans Schultes & Blas Pablo Reko 231*, Harvard Botanical Museum Collections (Economic Botany) No. 5548.

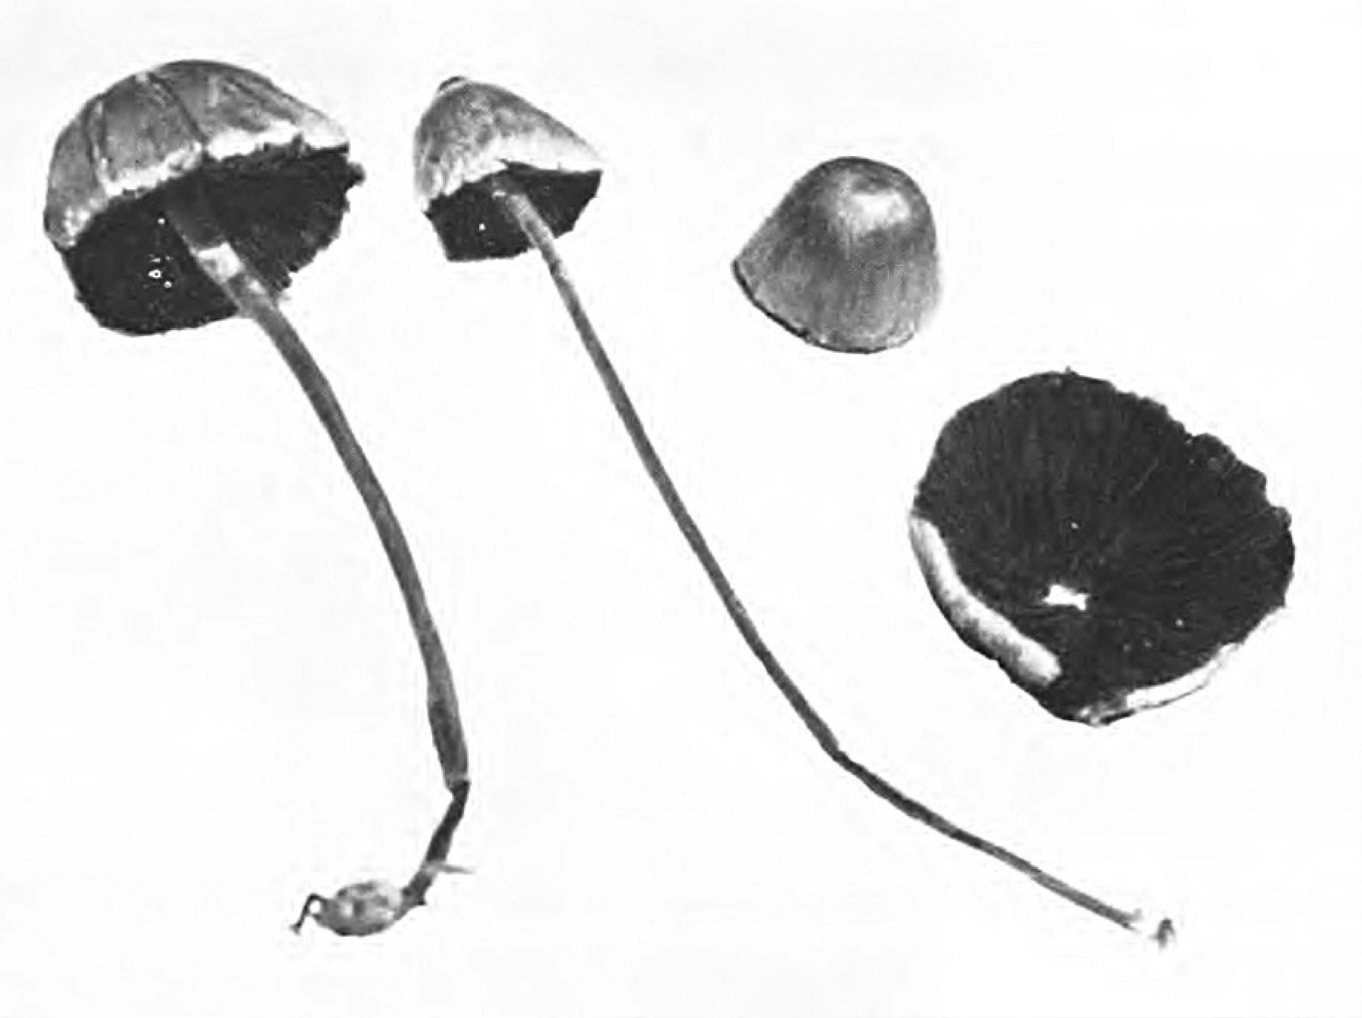
COMMON NAMES: Aztec - *nanacatl* ("mushroom") , *teonanácatl* ("sacred mushroom"), *quauhtlananacatl* ("wild mushroom"); Mazatec - *t-ha-na-sä* (meaning unknown), *she-to* ("pasture mushroom"), *to-shka* ("intoxicating mushroom"); Otomi - unknown.

The Oaxacan specimens, upon which this identification of *teonanácatl* is based, agree closely with the variety of *Paneolus campanulatus* L. which was made by the reduction of *Agaricus (Paneolus) sphinctrinus* Fr. to varietal rank. They lack, however, the pronounced appendiculate margin which is figured by Bresadola (8). The mushrooms are small, never more than ten centimeters in height. The dark brown stipe is terete and very slender and measures from one to two millimeters in diameter; the dark color of the stipe serves to separate this species from the closely related *Paneolus papilionaeeus* Fr. The pileus, three centimeters in diameter and one half centimeter in height, is usually somewhat conical (perfectly hemispherical in a few specimens), slightly cuspidate, and of a light yellowish-brown color. The gills are spotted and are dark brownish-black. The spores, varying from 12-15 x 7.5-8.3µ, are black. This mushroom and its close relatives *Paneolus campanulatus* L. and *P. papilionaceus* Fr. are exceedingly widespread, occurring on all the major continents.

---

[1] I wish to express my thanks to Dr. David Linder of the Farlow Herbarium, Harvard University, who corroborated field identifications and rendered further taxonomic assistance.

Among the Mazatec Indians, *Paneolus campanulatus* var. *sphinctrinus* is regularly used by some members of the tribe as a narcotic. The plant does not appear to be common in the Mazatec country. It grows in pastures and open fields during the rainy season from June to September. Those who use it search for it eagerly, gathering and drying it for future use. Because the mushroom is regarded as being semi-sacred, it is difficult to purchase specimens. They are usually presented as a gift.



Paneolus campanulatus L. var. *sphinctrinus* (Fr.) Bresadola

There are among the Mazatecs professional divinators who earn a livelihood by endeavoring through mushroom intoxication to locate stolen property, discover secrets, and give advice. The narcotic is taken to induce a semi-conscious state accompanied by a mild delirium. The incoherent utterances made during intoxication are interpreted as prophetic or admonitory. This, curiously enough, parallels the use of ololiuqui (the seeds of *Rivea corymbosa* (L.) Hall. f.), a convolvulaceous narcotic which is still used in parts of Oaxaca, and of various species of *Datura* which are very widely employed to induce a delirium that is thought to assist in divination and witchcraft.

The professional Mazatec divinators evidently store large numbers of these mushrooms for use throughout the year, for the doses said to be required for intoxication are large. It was impossible to learn whether these divinators practice their art exclusively with *Paneolus* or whether they are general *curanderos* (herb-doctors) as well. They are said to age rapidly, probably because of frequent ingestion of the slightly poisonous *Paneolus*: at the age of thirty-five, senility is apparent.

It was impossible to ascertain the extent of this profession, but the use of the narcotic is by no means confined to the divinators. Any individual may eat the mushrooms. That the consumption of the fungus is large is borne out by the fact that it was with difficulty that we were able to secure 4 two dozen specimens. Johnson (9) has learned that certain "narcotic mushrooms" are of importance in Mazatec witchcraft, and it is probable that these also are referable to the genus *Paneolus*.

The doses which the Indians employ vary with the size and age of the individual. Usually fifteen mushrooms are sufficient to induce the desired effect, but larger doses are reported. Overdoses of fifty or sixty mushrooms result in poisoning, while continued use of excessive quantities is said to produce permanent insanity. Whether or not this is true could not be ascertained.

According to Indian descriptions, the intoxication lasts about three hours. Shortly after ingestion of the mushrooms, a general feeling of exhilaration and well-being is experienced. This state of exhilaration is followed within an hour by hilarity, incoherent talking, and later, is accompanied by fantastic visions in brilliant colors, similar to the visions so characteristic of peyote-intoxication (*Lophophora williamsii* (Lem.) Coulter).

Paneolus is known to be slightly poisonous and narcotic. With the exception of Mexican Indians, I am aware of no primitive peoples who take advantage of the properties of this genus for intoxication. The effects of *Paneolus* have been studied (5, 6, 12) and the symptoms of the intoxication are similar to those of alcoholic-intoxication. Ford (6) has divided mushroom-poisoning into five categories: the choleriform type (*Amanita phalloides* (Fr.) Quel.); the nerve-affecting type in which occur convulsions and coma often resulting in death, (*Amanita muscaria* (L.) Pers. and other muscarine-containing forms); the gastro-intestinal type which is seldom fatal; the blood-dissolving type; and the cerebral type. Paneolus-intoxication belongs to the last category of poisonings. It is characterized by exhilaration, fantastic visual hallucinations, a feeling of ease and well-being, muscular incoordination, drowsiness, a staggering gait or difficulty in walking, emotional excesses, laughter, incoherent and uncontrolled speech, and mydriasis. The effects following ingestion are always of short duration.

It is of significance that the description of Paneolus-intoxication by Douglas (5) and Krieger (12) is practically identical with that given by the Mazatec Indians and with descriptions found in early Spanish accounts of the use of *teonanácatl* among the Aztecs.

III. Historical background of teonanácatl

The first attempt to identify *teonanácatl* botanically was made in 1915, when Safford (18, 19) published his conclusions that the so-called "mushroom" was, in reality, a part of the cactus *Lophophora williamsii* (Lem.) Coulter and, notwithstanding the numerous independent reports and descriptions in literature, was not a fungus.

After a careful study of herbarium specimens, Safford failed to find a Mexican mushroom with narcotic or intoxicating properties. Safford (19) states: "Three centuries of investigation have failed to reveal an endemic fungus used as an intoxicant in Mexico, nor is such a fungus mentioned either in works on mycology or pharmacography; yet the belief prevails even now that there is a narcotic Mexican fungus...". This induced him to search among other plants and plant products for something which the early writers or the Indians might have confused with a dried fungus. He believed that the dried, brown, discoidal head (mescal button) of the spineless peyote-cactus (*Lophophora williamsii*) resembled "a dried mushroom so remarkably that, at first glance, it will even deceive a mycologist" (19). Peyote was used by the Aztecs as a religious narcotic during this same period, and the symptoms of intoxication were described as somewhat similar, especially in the production of fantastic visual hallucinations. It should be emphasized, however, that there is actually little similarity in appearance between mescal buttons and the dried pilei of *Basidiomycetes*: the shrivelled crowns of *Lophophora williamsii* assume the drab color of a dried mushroom, it is true, but a heavy cushion of closely placed areolate tufts of silky hairs densely clothes the upper surface of the dried cactus-head, while the fibrovascular region is clearly visible on the lower surface. It seems improbable, therefore, that either the historians or the Indians were deceived by a superficial color-resemblance.

However, Safford (18, 19) based his conclusions: 1) on the apparent absence from Mexico of narcotic or intoxicating mushrooms and 2) on the supposed similarity between mescal buttons and dried mushrooms. He concluded that the Aztec Indians, who gathered for use both *peyote* and *teonanácatl* and whose botanical knowledge and powers of observation were keen, had failed to recognize the hard, wrinkled, brown mescal buttons as a part of the soft, succulent, green peyote-plant of the desert. The former, he assumed, they called *teonanácatl*, the latter *peiotl*.

Furthermore, Safford had at his command a number of the detailed descriptions of the early writers on Mexico. He failed to see in these, however, any overwhelming negation of his identification of *teonanácatl*. As La Barre (14) aptly states: "Safford identifies the two by a somewhat casual use of his evidence and mystifies himself with the consistent contradiction offered by all the early Spanish writers to his assumption. He composes the contradiction by assuming that the Aztecs did not recognize the dried, discoidal button as the same plant as the green cactus; despite overwhelming etymological evidence, he supposes they called the former '*teonanácatl*' and the latter 'peyotl'".

Much of the work done by Safford in the identification of important and interesting economic plants of ancient Mexico was brilliant. It is not surprising, therefore, that workers were inclined to accept his treatment of *teonanácatl*. Safford's erroneous identification unfortunately was generally accepted and has become rather firmly established in both botanical and anthropological literature.

Until recently, no published objections were raised against Safford 's identification. From the first, however, Doctor Bias P. Reko maintained that peyote and *teonanácatl* were not identical. Reko has carried out rather extensive botanical collecting and anthropological investigations of several kinds in Mexico for more than a quarter of a century. From his own experience and from a belief in the dependability of the early reports, he insisted on the presence of a narcotic mushroom among Mexican Indians. Thus, in 1919, he stated (15) that *nanacatl* was "div. géneros de hongos, especialmente un hongo negro que crece sobre estiércol y produce efectos narcóticos," and in 1923, he wrote as follows in a letter[2]:

> "… I see in your description of *Lophophora* that Dr. Safford believes this plant to be the '*teonanácatl*' of Sahagun which is surely wrong. It is actually, as Sahagun states, a fungus which grows on dung-heaps and which is still used under the same old name by the Indians of the Sierra Jaurez in Oaxaca in their religious feasts...".

The first published objection to Safford's identification appeared in 1937 (17): "Dem [the Safford identification] muss widersprochen werden. Die Nanacates sind Giftpilze, die mit Peyote nichts zu tun haben. Seit alten Zeiten ist es bekannt, dass ihr Genuss Rauschzustände, Extasen, und Geistesstörungen hervorruft, aber trotz ihrer Gefährlichkeit hat man sie überall, wo sie vorkommen, wegen ihrer berauschenden Eigenschaften bis auf den heutigen Tag geschätzt". V. A. Reko (17) suggests, but without corroboration or evidence, that *nanacatl* might be a species of *Amanita*. This refutation of Safford's identification, however, is important inasmuch as it once more centered attention on the problem. In 1937 and in 1938, I (23, 24) summarized the evidence against the identity of peyote and *teonanácatl*, and in 1938, La Barre (13) also indicated his doubts of Safford's identification.

Fray Bernardino de Sahagun (c. 1499-1590) was the first European to record the use of *teonanácatl* as a narcotic. There are several distinct references to this plant in his *Historia de las cosas de Nueva España* (20). One of these references, in a general consideration of useful plants, states that:

> … they [the Chichimecas] possessed a great knowledge of plants and roots, and they were acquainted with properties and virtues of them; these same people were the first to discover and use the root which they called *peiotl*, and those who are accustomed to eat and drink them used them in place of wine; and they did the same with those which they call *nanacatl*, which are harmful mushrooms which intoxicate in the same way as wine ...

A more detailed report of *nanacatl* is to be found in a chapter devoted to the consideration of narcotic and intoxicating plants:

> There are some small mushrooms in that region which are called *teonanácatl*; these grow under the grass (hay) of the fields and pastures. They are round, having a rather high stipe, slender and terete. When eaten, they have a bad taste, hurting the throat, and they cause intoxication. They are medicinal for fevers and for rheumatism. Only two or three need to be eaten. Those who eat

---

[2] Letter: B. P. Reko, Guadalajara, Mexico, to J.N.Rose, United States National Museum, Washington, D.C., July 18, 1923; herbarium sheet No. 1745713, United States National Herbarium, Washington, D.C.

> them see visions and feel a faintness of the heart. And they provoke to lust those who eat a number, or even a few, of them.

In the first of these excerpts, Sahagun clearly distinguished between "the root which they call peiotl" and "*nanacatl*, which are harmful mushrooms." Likewise in his chapter on narcotic plants from which the second excerpt is taken, Sahagun discussed the "small mushrooms ... which are called *teonanácatl*" and in another paragraph recognized *peiotl* as a distinct plant:

> There is another herb like the earth-tunas which is called *peiotl*. It is white and grows in the north. Those who eat it see terrifying and amusing visions. The intoxication persists for two or three days and then stops ...

In a third reference to the mushrooms, Sahagun explained the intoxication in great detail:

> The first thing which they ate at the gathering was small, black mushrooms which they called *nanacatl*. These are intoxicating and cause visions to be seen and even provoke sensuousness. They ate these [mushrooms] before dawn, and they also drank chocolate before daylight. They ate these little mushrooms with honey, and when they began to be excited by them, they began to dance, some singing, others weeping, for they were already intoxicated by the mushrooms. Some did not want to sing but sat down in their quarters and remained there as if in a meditative mood. Some saw themselves dying in a vision and wept; others saw themselves being eaten by a wild beast; others imagined that they were capturing prisoners in battle, that they were rich, that they possessed many slaves, that they had committed adultery and were to have their heads crushed for the offense, that they were guilty of a theft for which they were to be killed, and many other visions which they saw. When the intoxication from the little mushrooms had passed, they talked over among themselves the visions which they had seen.

From Sahagun's three references, it is obvious that the root-word *nanacatl* meant "mushroom." Teo*nanacatl* probably was the correct word for the narcotic species, and *nanacatl* served as a more general term. This more general use is found in still another one of Sahagun's botanical references to mushrooms:

> The cone-shaped mushrooms (*nanacatl*) *genus campos agrorum* in the mountains are good to eat. They are cooked for this purpose; if they are eaten raw or poorly cooked, they produce vomiting or diarrhea, and they may kill.

Further evidence of the meaning of *nanacatl* is found in the various combinations which were made by adding prefixes denoting the color, habitat, or attributes of the plant. Hernandez (8) describes the narcotic mushroom under the heading: "De *nanacatl* seu Fungorum genere." He considered *teonanácatl* as *teyhuinti* or "intoxicating", distinguishing from it several other types of mushrooms: *iztacnanacame* (white mushrooms), *tlapalnanacame* (reddish mushrooms), and *chimalnanacame* (yellow-orbicular mushrooms).

Jourdanet and Siméon (21) define *teonanácatl* as follows: "(*Teonanácatl*) c'est à dire: champignon dangéreux. La terme générique est *nanacatl*, qui se met en composition avec d'autres mots pour désigner les diverses espèces de champignons."

Siméon (26) analyzes several words with *nanacatl* as a root and clearly points out the meaning of the term:

"*Nanacatl* - Champignon; *quauhtla-nanacatl*, champignon des bois; au fig. *nanacatl nicte-ittitinemi* (Olm.), rendre quelqu'un pervers, lui donner de mauvais conseils. En comp.: *nonanac* ou *nonanacauh* (Olm.), mon champignon. R. *nacatl*?"

"*Nacatl* - Chair, viande; ... *nonac*, ma viande, la chair que je mange."

"*Teonanácatl* - Espèce de petit champignon qui a mauvais goût, enivre, et cause des hallucinations; il est medicinal contre les fièvres et la goutte (Sah.) RR. *teotl*, *nanacatl*."

"*Teyhuinti* - Qui enivre quelqu'un, enivrant; *teyhuinti nanacatl*, champignon enivrant."

An additional piece of evidence may be found in the use of the word *nanacatl* in modern Mexico. In provision markets of Mexico, mushrooms in general are called *nacatl* (17).

Serna (25) recorded a very complete description of *teonanácatl* and its use as a narcotic and clearly distinguished it from peyote:

> And it so happened that an Indian had come ... bringing some of the colored mushrooms which are gathered in the hills, and, with these, he had performed a great idolatry. But before explaining this [idolatry], I wish to explain the nature of the said mushrooms which, in the Mexican language, are called *quatlannamacatl* ... these mushrooms were small and yellowish, and to collect them the priests and old men, appointed as ministers for these impostures, went to the hills and remained almost the whole night in sermonizing and in superstitious praying. At dawn, when a certain little breeze which they know began to blow, they would gather them [the mushrooms], attributing to them deity. They have the same effects as ololiuqui and peyote, for when they are eaten or drunk, they intoxicate, depriving those who partake of them of their senses and making them believe a thousand absurdities.

Benvento in Kingsborough (10) reports the use of mushrooms for intoxication:

> They had another kind of intoxication...which was induced by small toadstools or mushrooms ... which are eaten raw. Because of the bitter taste of these mushrooms, they drink after them or eat with them a little honey after which they shortly see a thousand visions, especially snakes. They went raving mad, and they ran about the streets wildly ... In their language they called these mushrooms *teunamacatlth*, a word which means "bread of the gods...".

Basing his statement on the etymology proposed by Siméon (21,25), LaBarre (14) points out that Benvento's etymology is wrong. The belief that *teonanácatl* means "bread of the gods" or "flesh of the gods" is widespread. Thus, in an unpublished manuscript, V. A. Reko (16) applies the meaning of "divine food of a soft or fleshy nature" to *teonanácatl*. Safford (18, 19) consistently used the expression "flesh of the gods." Bancroft (l), in speaking of the intoxicants of the Nahuatls, wrote: "Among the ingredients used to make their drinks more intoxicating, the most powerful was the *teonanácatl*, 'flesh of the gods', a kind of mushroom which excited the passions and caused the partaker to see snakes and divers other visions."

There are numerous less explicit references to the use of mushrooms for intoxication in Mexico. These have no common names or descriptions which might serve to identify the plant, but it is probable that some of the references concern the same species of *Paneolus* which has been identified as *teonanácatl*. One of these references (11) relates that visitors who had come to the coronation of Montezuma were offered "wild mushrooms" to eat; these intoxicated them and made them dance. Duran, quoted by Bourke (2) states that after the sacrifice of human beings at the coronation of Montezuma II, the multitude ate raw mushrooms and that these induced an intoxication which was much stronger than alcoholic-intoxication; many committed suicide during the height of the intoxication; some received visions and were, in this way, permitted to foresee the future. It is probably safe to assume that the plants spoken of in these two instances were the *teonanácatl*, *Paneolus campanulatus* var. *sphinctrinus* or a related species. The great similarity in the intoxication to that which Ford (6) has described for *Paneolus* would seem to suggest that the intoxicant was a member of this genus.

Thompson (27) reports Saville as stating that Tizoc, an Aztec ruler who was poisoned after a five year reign, may have been killed by the substitution of poisonous mushrooms for the intoxicating kind which were normally eaten at ceremonies. It is probable that, if this were the case, the deadly *Amanita phalloides* (Fr.) Quél, was the instrument of death. Since this extremely poisonous mushroom could never be overlooked and mistaken for a species of *Paneolus*, it argues that the mushrooms must have been utilized dry, in which condition substitution would have been less difficult.

The discovery of the use of *Paneolus campanulatus* var. *sphinctrinus* as a narcotic among the Mazatecs of Oaxaca and its identification as the *teonanácatl* of ancient Mexico greatly enhances our knowledge of the useful Basidiomycetes. While the genus *Paneolus* has been known to have poisonous and narcotic properties, its use for intoxication has not been reported, so far as I have been able to learn, for any primitive peoples outside of Mexico. *Amanita muscaria* (L.) Pers., the fly-agaric, has been used somewhat ritually as a narcotic intoxicant by the natives of Kamchatka, and this has received rather intensive botanical, chemical, medical, and ethnological study for many years. *Amanita muscaria*, like *Paneolus campanulatus* var. *sphinctrinus*, is widely spread, but its use as a definite narcotic is confined to the relatively small Kamchatka area of northeastern Siberia, as the use of *Paneolus campanulatus* var. *sphinctrinus* as a narcotic is apparently known only from Mexico. Dorman in Bourke (2) reports that mushrooms were worshipped in the Antilles, in Virginia, and in California. Such a practice might be interpreted as indicating possibly a former use of the plant as a narcotic to produce oracular delirium. Possibly, however, the reverence accorded to the mushrooms is due to other entirely unrelated causes.

IV. Summary

1. *Paneolus campanulatus* L. var. *sphinctrinus* (Fr.) Bresadola is used as a narcotic in daily life and in divination and witchcraft among the Mazatec Indians of northeastern Oaxaca.
2. A species of *Paneolus* is employed as a narcotic by the Otomi Indians of Puebla and adjacent regions.
3. The size, color, form, growth habits, uses, and narcotic effects of *Paneolus campanulatus* var. *sphinctrinus* correspond so closely to the descriptions of the same aspects of the hitherto unknown *teonanácatl* of the early Mexican writers that there can be little doubt that this species represents the intoxicating mushroom which was in very wide use in daily life, in ceremonies, and in divination and witchcraft among the Aztecs and Chichimecas at the time of the Spanish Conquest.
4. The discovery of the use of *Paneolus campanulatus* var. *sphirictrinus* as a narcotic and the identification of this fungus with *teonanácatl* should dispel the confusion which has resulted in literature from Safford's misidentification of *teonanácatl* with peyote.
5. References in the early literature indicate that the Aztecs possessed an extensive knowledge of the useful and harmful Basidiomycetes.
6. Although species of *Paneolus* are found all over the world and are known to possess intoxicating or slightly poisonous properties, no reference to their use as narcotics is known for primitive peoples outside of Mexico.

Mazatec sexual impurity and Bible reading

by

Eunice V. Pike

Eunice V. Pike is a missionary of the Wycliffe Bible Translators,
with many years of experience among the Mazatecs of southern Mexico.
She is one of the translators of the Mazatec New Testament.
Miss Pike was co-author of "Mushroom Ritual vs. Christianity,"
which appeared in the July-August (1959) issue of PRACTICAL ANTHROPOLOGY.

original text: http://www.mushroomjohn.org/pike1.htm

The point has repeatedly been made that the hearing of the gospel is filtered through presuppositions created by cultural ideas, experience, and world view. Sometimes this distortion in the reception of the message can result in complete misunderstanding. Occasionally the missionary has no idea of the interference involved. The following account is the story of a slowly awakening consciousness which came to Miss Pike in her work among the Mazatecs, an awareness of the set of assumptions which governed people's ideas about the Bible. It also discusses efforts to teach in such a way that the communication difficulty is overcome.

Spirits and Ceremonial Cleanliness

Over a period of years I have gradually become aware of the fact that Mazatecs consider sexual relations to be offensive to "God" and in fact to any spirit. If they have not had intercourse for a time, they are said to be "clean," otherwise they are "sinful." For fear of being punished by the spirits, the Mazatecs try to be ceremonially clean whenever they come in contact with them.

When contacting "Christ" by means of the sacred mushroom[1], they are supposed to refrain from intercourse about four days both before and after the mushroom ceremony. If they do not, it is said that the mushroom may make them crazy.

[1] See Eunice Pike and Florence Cowan, "Mushroom Ritual vs. Christianity," PRACTICAL ANTHROPOLOGY, Vol. 6, No. 4 (July-August 1959), pp. 145-150.

The same restriction is applied to witchcraft which they use to contact evil spirits, trying to pay them to harm another human being, or to stop harming some member of the family. If they are not "clean" when they use witchcraft, the spirits will punish them, perhaps by making them crazy, or perhaps by killing their children.

Parents must abstain for forty days whenever there has been a death in the family. If they do not, one of the children may die. During a whooping cough or measles epidemic, when one child dies, and then another, the neighbors gossip about the parents, saying, "They killed them by not remaining clean." To the Mazatec spirit world there is no difference between adultery and the sexual relations within marriage; they are equally "sinful."

To many Mazatecs the sun is God, and although he is a "good" god he also punishes for sexual relations. Specifically, if a man has prostate trouble, the people say it was because, sometime in his life, he had intercourse outdoors, that is, in the presence of the sun.

One Mazatec was reported to have studied a book called *The Prayers of James*. I was told that this book teaches a person how to steal. He can go through a door without opening it; he can walk into a room and steal without people seeing him. Later the man became "crazy." His relatives and people of his vicinity decided that he must not have been "clean" when he studied the book, and for that reason he had gone crazy.

Cleanliness and the Reading of the Scriptures

When I tried to interest Mazatecs in reading the Bible, I told them that it is the Word of God. When they did not respond, I thought they were not convinced. Now I suspect that sometimes they do not respond because they are convinced and have applied to the Scriptures the same restrictions that they apply to the mushroom, witchcraft, or a book of magic[2]. Specifically, they are afraid to read Scripture unless the are "clean."

[2] For similar ideas of "ritual purity" see Edward Norbeck, "pollution and Taboos in Contemporary Japan," *Southwestern Journal of Anthropology*, Vol. 8 (1952), pp. 269-285. He says that at the present time menstruation, childbirth, and death are the major sources causing ceremonial impurity. Avoidance of Shinto deities at such times is still practiced in some rural communities. In former times sexual intercourse was another cause of ceremonial impurity.

They say that the Scriptures are *xcon*^{1}, a difficult word to translate into English. When applied to a flood, or a strong wind, it seems to carry the meaning of 'dangerous' or 'awesome.' When applied to medicine, it means that caution must be used, and that if it is taken unwisely it might be harmful. I once thought of *xcon*^{1} as 'holy' when applied to a cross or a saint. Now, however, I would translate it with the more inclusive term of 'powerful' and point out that the power may be either good or bad.

It was the weight of a number of incidents that began to lead me to the conclusion that Mazatecs are afraid of the Bible. For example, a man who was a town leader was eager to hear the gospel. He came and asked us to teach him. He prayed, asking the Lord to forgive his sins and to bless his family, but although he was educated and capable of reading the Scriptures, he would never read them for himself. When I persisted, urging that he read at home, he objected with, "People say that we will go crazy if we read God's Word."

A young fellow who had been reading Scripture told me that he was considering marriage. He wanted to know if he could go on reading or if he must stop.

A widow, now a Christian, said, "I used to be a sinner, but gradually I'm becoming clean." When I questioned her, she explained that when her husband had been living she was sinful, but since his death she was gradually becoming clean.

I suspect that the statement, "We are all sinners," in some contexts would mean, "None of us are virgins." Or, looking at it from the other direction, one of the Mazatec terms for 'virgin' is *cho*^{4}*ta*^{4}*tsje*^{3} which translated literally means 'clean person'[3].

[3] Lorna Gibson, who has been working with the Pame Indians of San Luis Potosí, Mexico, says that they make no distinction between adultery and marriage relations. That is, both are regarded as sinful. She backed up her statements with these illustrations: (1) A young man wanting to do what was right, but also wanting to marry, asked with concern, "Is it a great sin for a man to take a wife?" (2) A Pame speaking of a recently married girl said of her, "She's a sinner now; she's married." (3) The Pame expression for "virgin" when translated literally means "woman-still-holy."
Mary Shaw, working with the Achi Indians of Guatemala, says that one man said to her, "I'd like to become a Christian, but if I did I'd have to stop living with my wife, wouldn't I?"
Esther Matteson, working with the Piro of Peru, tells of the time she and her translation helper first went over Heb. 13:4. He was amazed and thrilled, and he questioned her to be sure that he had understood the meaning of "Marriage is honourable in all, and the bed undefiled; but whoremongers and adulterers God will judge." Ten he got up from the translation table and literally rushed out to call the men of the village together and tell them the good news. His wife had a meeting with the women, and they were told. They had all known that adultery was wrong, but that marriage relations were not sinful was good news indeed.

In order to learn more fully whether or not Mazatecs believed that they must be "clean" in order to read Scripture, I asked a Christian widow, "Why are people afraid to read God's Word?" She answered, "Probably they are not clean. But I was never afraid - not even when my husband was living."

I asked a Christian mother with three young children the meaning of *cjoa*^{4}*fi*^{3}*tson*^{3}*ntjai*^{2} ;thing-destroy-behalf-of,' which is the word people use when several children in one family die. Her answer was vehement, "That's a bad word. Don't ever say it again!" I persisted - although I was careful not to tell her what I suspected about the word. I asked, "Is it really bad? I thought it had something to do with funerals." She was my friend and she wanted to help, so hesitatingly she told me, "It's what ... and ... [she named a husband and wife] did. That's why ... was born." Then again she was vehement. "It's a bad word. I don't believe it. People just say so. I've followed Jesus since I was a little girl, so I don't know what they are talking about."

But all the time she was talking, she kept putting in a little grammatical particle that indicates the speaker's doubt about what she was saying. She didn't really know that she was telling the truth and anybody who felt that strongly would probably like to *know*. So I said softly, "I don't believe it either." Then I made a bargain with her. "I'll tell you what God's Word says, if you'll tell me what the old people say." So I told her that there is a difference in God's sight between adultery and the marriage bed.

That was what her conscience had been telling her, but she had had no assurance. Then she kept her half of the bargain. She told me that the old folks say that if people use witchcraft while not "clean" some member of the family may die. Their term for that type of death was the word she had objected to. She was relieved to find out that the Bible does not consider the marriage bed sinful.

Her reaction gave me the courage to talk to another young married woman, who had been my informant about ten years ago. She had loved the Mazatec hymns. She had learned to read Mazatec Scripture fluently and she did so with interest. She had led in prayer, and I considered her to be genuinely Christian. There was a young fellow in the same town who was also interested in the gospel. He too sang hymns and read Scripture. They married and I was delighted. "The first Christian family!" I thought.

But they stopped reading Scripture. They stopped growing spiritually. I urged to no avail. They were still my friends, and as time passed they sent their children to me to be taught about the Lord. The wife still sang hymns; in fact she could sing about sixty of them in Mazatec and half that number in Spanish. Why had she stopped reading Scripture?

I began to suspect that I knew the answer. So one day I told her, "Some people say that it's *xcon*[1] to read God's Word when a man and wife are living together. That is not so." I told her about Adam and Eve, and that Noah was told to replenish the earth. "God doesn't object to you and your husband living together, and it pleases him when we study his Word." She listened very quietly. No comment.

Two days later her eight-year-old son came running down, "Mother wants to know when you are coming up to study." So I went up. Her face was shining with joy. She picked up the New Testament (she enjoys trying Spanish). She had found the Lord's Prayer and she was delighted. She had also been reading the Gospel of John in Mazatec. That was the first time in ten years that I had seen evidence of either her or her husband reading the Bible for themselves.

There was another young wife, mother of two children, who sent her children to study, and she herself wanted to be taught. One day she brought money with which to buy a hymn book, but before she bought it she asked with hesitation, "Is this book *xcon*[1]? Can I read it every day? Are there days when I should not read it?" By that time I knew the reason for her hesitation, so I answered, "This book will not hurt you. I am the youngest of eight children. My father read the Bible every day and yet none of us died in childhood. God likes to have us read his Word." She bought a hymn book and later came back to buy all the Scripture that is in print in Mazatec.

By that time I was ready to understand strangers when they delicately asked about "cleanliness" and "sin." One day as I entered a Mazatec market with books for sale, a man stopped me and asked, "Do you have a book that tells us how to get forgiveness for sin?" I started to pull out the First Epistle of John but he stopped me. "I can't read; just tell me." I thought that he was probably talking about the "sin" of uncleanliness - they are seldom concerned about any other sin - but I answered for sin in general. "We pray to the Lord" (I made sure that he knew what God I was talking about) "and tell him that we are sinners and ask him to forgive us."

The man suspected that I was talking about sin in general and he was not satisfied. He wanted to be sure that it applied to that one specific sin. So he explained, "I am a man and I have a wife. Can I be forgiven the sin of living with my wife?" Now I should have explained that living with one's wife is not sin, but I was embarrassed to talk about such things in the middle of a market, so I said simply, "Yes." But he wanted to be sure that he understood, so he said, "I can have lots of women, and all I have to do is say, 'I'm a sinner, please forgive me,' and he will." Middle of the market or not, I couldn't let that pass, so I differentiated between adultery and the marriage bed. I was surprised and grateful to notice that the people who gathered around were listening as though they wanted to know the answer, end not even one made a crude remark.

Conclusion

The task of getting such a message out to all Mazatecs seemed so great that I did not want to believe the evidence. I decided to check with some of the Christian men. At my request, my colleague Julian Lloret questioned the young man who had helped George Cowan in the translation of the New Testament and who is also the one who heads up the tiny group of Christians in the biggest Mazatec town. This young man confirmed the fact that Mazatecs consider the Scriptures to be "powerful" and that they are afraid to read them unless "clean." He was surprised, however, that we needed to ask because, according to him, people make that objection "all the time" when we are selling Scripture in the market. Lloret asked if the restriction applied to man and wife, or only to extra-marital relations. The reply was that it applied also to man and wife - "but we don't believe that, do we?" Even he wanted to be assured that God does not object to sexual relations in marriage.

We wanted to be very sure of our conclusions, so Lloret asked another young man who had left the tribe about ten years previously. He agreed with our data, and as a mature Christian he went on to give us some advice. "You must tell them that the Bible is different. They don't have to be clean to read the Bible. It's the Bible that cleans!"

That was a good suggestion and we have been looking for other answers in the Bible. There is Ruth 4:11 in which the people say of Ruth, "The Lord make the woman ... like Rachel and like Leah." In 1 Sam. 1:10, 11 Hannah prayed for a child and the Lord answered her prayer. In Joshua 1:8 the people are told to read the Bible every day. In 1 Cor. 7:5 a couple is told not to refuse each other unless it be my mutual consent. In 2 Sam. 11 and 12, by means of the example of David with Bathsheba, we are taught the difference in God's sight between adultery and marriage relations.

The Scripture is explicit in Heb. 13:4, but until our eyes were opened to the Mazatecs' confusion, we did not know enough to apply it. Now that we have a clearer understanding of the Mazatec fears and beliefs we hope that the distribution of Scripture and the growth of the church will go ahead faster.

Fly-Agaric Motifs in the Cú Chulaind Myth Cycle

Introduction

The ancient myths of Ireland include many fabulous tales regarding Cú Chulaind, a warrior of the Ulaid clan who lived in the province of Ulster. Some of these portray Cú Chulaind's legendary moodswings: at one extreme, a battle-fury so intense that it terrified even his family, friends and fellow warriors; at the other, a torpor with vivid, prophetic dreams in which he languished for a year. It strikes me that aspects of both of these states, as described in the tales, resemble the effects of ingesting *Amanita muscaria*, the psychoactive mushroom with a bright red cap and white "speckles" also known as the fly-agaric.

This connection is especially significant in light of recent theories which suggest that many ancient Irish myths contain thinly-veiled allusions to *Amanita muscaria*. Peter Lamborn Wilson was among the first to point this out in his 1995 article "Irish Soma."[2] According to him it is likely that the Celts who settled Ireland either used it there in rituals or remembered that it had been used by their ancestors prior to migrating westward from an "Indo-European heartland" near the southwestern edge of Siberia. Wilson calls it "Irish Soma" because *A. muscaria* also is considered a strong candidate for Soma, the unknown plant substance praised as a god in the Hindu *Rig Veda*. It is a curious but well-established fact that there are numerous strong similarities between the culture of the Irish Celts and that of the Aryan peoples who migrated southward to India from the same heartland, bringing with them an oral tradition of hymns that became the *Rig Veda*.[3] Some even think the name "Ireland" derives from a Celtic word, "Erin," which is based upon or shares a common root with the Sanskrit "Arya."[4] In Wilson's view, both cultures almost certainly first learned about the entheogenic effects of *A. muscaria* from Siberian shamans in the Indo-European heartland.

Support for Wilson's theory has been offered by Erynn Rowan Laurie and Timothy White in their *Shaman's Drum* article, "Speckled Snake, Brother of Birch: Amanita Muscaria Motifs in Celtic Legends," which contends that motifs of magical foods in Irish Celtic lore are best explained as "metaphoric references to *Amanita muscaria*, the highly valued psychotropic, redcapped mushroom that was once used shamanically throughout much of northern Europe." While agreeing that these references "could theoretically be faded memories of earlier pre-migration Indo-European practices, preserved in oral legends passed down from generation to generation," they think it more likely that Irish Celts actually used this mushroom in religious rituals. Their reason is that Celtic legends seem, in their opinion, to contain "certain innovative occult symbols for *A. muscaria* that are fairly unique to the insular Celts." They maintain that such symbols would not have been needed unless a sacred mushroom cult was still being practiced in Ireland by Celtic Druid priests "who wanted to communicate teachings about the sacrament's use to initiates, while maintaining a protective veil of secrecy around its identification."[5]

Considered together, these two articles and Wilson's recent book on Irish Soma[6] build a very strong case for the general theory that the myths of ancient Ireland reflect at least a lingering awareness of the psychoactive properties of *Amanita muscaria*. But none of them links *A. muscaria* directly to Cú Chulaind. For reasons discussed in the following pages, I think it plausible that he personifies this mushroom or at least its capricious effects. We will start by reviewing descriptions of Cú Chulaind's so-called "warp spasms" and "wasting sickness." Next we will look at reported effects of *A. muscaria* inebriation and compare them with these maladies. Finally, I will discuss the possibility that myths about Cú Chulaind may derive from a shamanic source in prehistoric times which also inspired the Soma cult of ancient India.

Cú Chulaind's Warp Spasms

The first of Cú Chulaind's two maladies is variously translated as "battle-fury,"[7] "battle frenzy," "battle ardor"[8] or - my personal favorite - "warp spasm."[9] It is always accompanied by a temporary physical distortion called a *ríastarthae*[10] or *riastradh*[11] which usually includes an aura-like glow around Cú Chulaind's head, described by various writers as the "hero's light"[12] or the "warrior's light."[13] He first exhibits this proclivity in childhood, when, as related in *Boyhood Deeds of Cú Chulaind* (*Macghnímhartha*), some other boys provoke him with a barrage of toy javelins, balls and "hurleys" - 150 of each. After knocking these missiles aside without much trouble, Cú Chulaind becomes a bit flustered:

> You would have thought that every hair was being driven into his head. You would have thought that a spark of fire was on every hair. He closed one eye until it was no wider than the eye of a needle; he opened the other until it was as big as a wooden bowl. He bared his teeth from jaw to ear, and he opened his mouth until the gullet was visible.[14]

At this point, understandably, the other boys decide that they have somewhere else to go. But Cú Chulaind, now out of control, begins striking them down. He thrashes fifty before he is stopped by his patron and maybe father, King Conchubur of Emuin Machae, who gently points out that he should have secured the protection of the other boys before he tried to play with them. In other words, he should not have presumed to barge into their games without asking permission. Cú Chulaind resolves instead that it is he who will protect the other boys, and all return to the playing field. After that he always wins no matter what they play, including a primitive version of golf, wrestling and "mutual stripping." (The rules of the latter are lost in obscurity, other than what is deducible from the report that Cú Chulaind "stripped them all so they were stark naked, while they could not take so much as the brooch from his mantle.")[15]

Another episode in *Boyhood Deeds* relates that when Cú Chulaind was seven years old he went for a ride in a chariot driven by King Conchubur's charioteer. Upon encountering three fierce warriors from another clan, Cú Chulaind kills them and cuts off their heads to keep as trophies. Next he leaps from the chariot onto an antlered deer and subdues it. Then he captures twenty swans by knocking them out of the sky with well-aimed stones. The deer is tethered to the chariot and trots along behind; the swans, likewise bound to the chariot, fly overhead; the heads presumably are swinging to and fro inside the chariot. So much excitement in one afternoon proves too much for Cú Chulaind, who finds himself having a warp spasm just as the chariot approaches home. According to the tale,

> When they arrived at Emuin, the watchman said "A man in a chariot is approaching, and he will shed the blood of every person here unless naked women are sent to meet him." Cú Chulaind ... said "I swear by the god the Ulaid swear by, unless a man is found to fight me, I will shed the blood of everyone in the fort." "Naked women to meet him!" shouted Conchubur. The women of Emuin went to meet Cú Chulaind gathered round Mugain, Conchubur's wife, and they bared their breasts before him. "These are the warriors who will meet you today!" said Mugain. Cú Chulaind hid his face, whereupon the warriors of Ulaid seized him and thrust him into a vat of cold water.

> This vat burst, but the second vat into which he was thrust boiled up with fist-sized bubbles, and the third he merely heated to a moderate warmth.[16]

It is related in another of the tales, *The Wasting Sickness of Cú Chulaind* (*Serglighe Con Culainn*), that all of the Ulaid women who loved him "blinded one eye in his likeness," because "it was Cú Chulaind's gift, when he was angry, that he could withdraw one eye so far into his head that a heron could not reach it, whereas the other eye he could protrude until it was as large as a cauldron for a yearling calf."[17] Also in this tale, which describes the hero's deeds as a young man, a third warp spasm comes upon him not long after he wakes from his year-long wasting sickness, described in the following section. This time he loses his cool (literally) during a furious battle in the land of Eithne Ingubai. Having just slaughtered thirty-four warriors, he finds it hard to stop even after the rest of the enemy army retreats. One of his own countrymen then says:

> "I fear that the man will turn his anger against us, for he has not yet had his fill of fighting. Have three vats of cold water brought, that his rage might be extinguished. The first vat that Cú Chulaind entered boiled over, and the second became so hot that no one could endure it, but the third grew only moderately warm."[18]

In the tale of *Briancu's Feast* (*Fledh Bhricrenn*), Cú Chulaind is challenged to "straighten" a house when, after lifting one side of it, he sets it down off-kilter. When he tries to comply but at first is unable to do so, the hero gets angry.

> Then his ríastarthae came over him: a drop of blood appeared at the tip of each hair, and he drew his hair into his head, so that, from above, his jet black locks appeared to have been cropped with scissors; he turned like a mill wheel and he stretched himself out until a warrior's foot could fit between each pair of ribs. His power and energy returned to him, and he lifted the house and reset it so that it was as straight as it had been before.[19]

Elsewhere in the Irish myths, Cú Chulaind's warp spasms are said to include: a booming heartbeat;[20] the ability to revolve within his own skin[21] and thus fight in multiple directions at the same time; the aforementioned "warrior's light" which rose from the crown of his head; the "warrior's moon," a projection "as thick as a whetstone" from his forehead; and a "stream of black blood [which] geysered from his skull as tall as a ship's mainmast."[22]

Cú Chulaind's Wasting Sickness

The title event of *The Wasting Sickness* is triggered when Cú Chulaind tries to capture a pair of enchanted birds flying over a lake. The song of these birds, who are joined by a red-gold chain, causes people to sleep. Though King Conchubur's wife warns him that "those birds possess some kind of power," Cú Chulaind twice casts stones at them - and misses! "Now I am doomed," he says, "for since the day I took up arms I have never missed my target."[23] He then throws his javelin at them and pierces a wing, but both birds manage to escape. After walking a while, the angry Cú Chulaind sits down with his back to a stone and there falls asleep. The story continues:

> While sleeping he saw two women approach: one wore a green cloak and the other a crimson cloak folded five times, and the one in green smiled at him and began to beat him with a horsewhip. The other woman then came and smiled and also struck him in the same fashion, and they beat him for such a long time that there was scarcely any life left in him. Then they left.[24]

When the Ulaid try in vain to rouse Cú Chulaind, Fergus, another hero, tells them: "No! Do not disturb him - it is a vision." At this point Cú Chulaind awakes, but cannot speak. For a year he remains in this state, confined to a sickbed, then slowly recovers. On hearing of his vision, King Conchubur counsels Cú Chulaind to return to the stone where he first fell asleep. There Cú Chulaind finds the green cloaked woman, who explains that she seeks his assistance as a warrior to fight on behalf of her people who dwell in the Sídh, a Celtic "other world." As noted by Mac Cana, the Sídh is a place of apparent contradictions whose people, though immortal, are not "permanently invulnerable nor exempt from violent death." The relativity of time and space is fluid there: "perspectives are reversed and brevity becomes length and length becomes brevity as one crosses the tenuous border between the natural and supernatural." Control of magic is the thing which most distinguishes lords of the Sídh from mortal kings and heroes,[25] as Cú Chulaind learns firsthand from his wasting sickness. When he tells the green-cloaked woman that he is "not fit to fight men," she replies: "That is soon remedied: you will be healed, and your full strength will be restored."[26] This comes to pass when an Ulaid woman later tells him: "Throw off sleep, the peace that follows drink, throw it off with great energy." Cú Chulaind then rises and, passing his hand over his face, at last conquers "all weariness and sluggishness."[27] It is during a subsequent battle which Cú Chulaind fights for the green-cloaked woman that he slaughters the thirty-four warriors while in warp spasm.

Effects of Amanita muscaria

Before proceeding it will be useful to review the main symptoms of Cú Chulaind's two maladies. Those exhibited during his warp spasm are: agitation (manic behavior, bristling hair); visual distortions (one eye protrudes, the other recedes); facial distortions (he grimaces and gapes, a thick "warrior's moon" projects from his forehead); tachycardia (booming heartbeat); blood rushes to his head (a drop of blood at the tip of each hair, a geyser of it spurts from his crown); light rushes to his head (a spark of fire appears at the tip of each hair, the "warrior's light" from his crown); he becomes very strong and very limber. He also becomes very hot, needing three successive dousings in vats of cold water before his temperature returns to normal. The symptoms of his wasting sickness are: sleepiness, vivid dreaming and prolonged lassitude.

Next let us review some eyewitness accounts of the effects of *Amanita muscaria* among Koryaks and other indigenous peoples of Siberia:

> [From an 1809 paper which describes the effects of fly-agaric mushroom eaten by Koryaks in Kamchatka:] The narcotic effect begins to manifest itself a half hour after eating, in a pulling and jerking of the muscles or a so-called tendon jump…The face becomes red, bloated, and full of blood, and…the head and neck muscles are also in a constantly convulsive state…According to their own statement, people who are slightly intoxicated feel extraordinarily light on their feet and are then exceedingly skillful in body movement and physical exercise. The nerves are highly stimulated, and in this state the slightest effort of will produces very powerful effects. Consequently, if one wishes to step over a small stick or straw, he steps and jumps as though the obstacles were tree trunks….[T]hese persons exert muscle efforts of which they would be completely incapable at other times; for example, they have carried heavy burdens with the greatest of ease, and eye-witnesses have confirmed to me the fact that a person in a state of fly-agaric ecstasy carried a 120-pound sack of flour a distance of 10 miles, although at any other time he would scarcely have been able to lift such a load easily.
>
> [From an 1893 book describing travels in Eastern Siberia from 1861-71:] When a Koryak consumes the fly-agaric…the mushroom seems to produce a peculiar effect on his optic nerves which makes him see everything on a greatly enlarged scale. For this reason it is a common joke among the people to induce such an intoxicated man to walk and then to place some small obstacle, such as a stick, in his way. He will stop, examine the little stick with a probing eye, and finally jump over it with a mighty bound. Another effect of the mushroom is said to be that the pupils become much enlarged and then contract to a very small size; this process is said to be repeated several times.
>
> [From a 1903 book based on two years of field research with Siberian tribes:] The effect…became evident by the time the men had swallowed the fourth mushroom. Their eyes took on a wild look…with a positively blinding gleam, and their hands began to tremble nervously….After a few minutes a deep lethargy overcame them, and they began quietly singing monotonous improvised songs…They suddenly sprang raving from their seats and began loudly and wildly calling for drums….And now began an indescribable dancing and singing, a deafening drumming and a wild running about…during which the men threw everything about recklessly, until they were completely exhausted. Suddenly they collapsed like dead men and promptly fell into deep sleep….It is this sleep that provides the greatest enjoyment; the drunken man has the most beautiful fantastic dreams.

> [From the diary of a Polish army officer, published in 1863, who was fed fly-agaric as medicine during a visit to Kamchatka in 1796 or 1797:] I ate half my medicine and at once stretched out, for a deep sleep overtook me. Dreams came one after the other. I found myself as though magnetized [mesmerized] by the most attractive gardens where ...a group of the most beautiful women dressed in white going to and fro seemed to be occupied with the hospitality of the earthly paradise....[Later, upon taking more of the mushroom,] I fell asleep anew and did not wake up for twenty-four hours. It is difficult, almost impossible, to describe the visions I had in such a long sleep...What I noticed in these visions and what I passed through are things that I felt I had seen or experienced some time before, and also things that I would never imagine even in my thoughts.

These are only a few of numerous such accounts collected by R. Gordon Wasson, the man who theorized that Vedic Soma was *Amanita muscaria*.[28] Many others have been published elsewhere,[29] including a recent report that copious perspiration can sometimes result from eating this mushroom, making it seem to objective observers as if the imbiber has "swallowed fire."[30] Similarities with aspects of Cú Chulaind's warp spasms and wasting sickness - as well as with his "salmon leap," the hero's fabled ability to jump across great distances or high into the air - would seem to be obvious.

The emphasis here is on aspects of Cú Chulaind's abnormal behavior corresponding to various symptoms of *Amanita muscaria* intoxication. The combined effect of these aspects in Cú Chulaind is exaggerated, making his deeds "more often seem superhuman than heroic," as one scholar noted.[31] There is nothing in the record to suggest that *A. muscaria* induces either lethal battle furies or year-long lassitude. Wasson, for example, was dismissive of the theory that the famous "berserk-raging" of the Vikings during battle was caused by ingesting this mushroom. Such "murderous ferocity," he noted, "is conspicuously absent from our eye-witness accounts of fly-agaric eating in Siberia."[32] However, it seems to me feasible that Cú Chulaind's warp spasms and wasting sickness represent exaggerated versions of the mushroom's true effects as perceived by observers and subjectively reported by its users, including ataxia (loss of muscle control), frenzied dancing in shamanic rites, amazing feats of strength, dramatic optical distortions, and disruption of sleep patterns lasting for several days with unusually vivid dreams.

Another interesting property of *Amanita muscaria* is that the urine of a person who ingests it becomes psychoactive. Apparently the chemical constituent that causes its psychoactivity metabolizes only rather slowly. Thus the Siberians have a long history, noted with astonishment by many Europeans, of drinking their own or another person's urine to prolong the mushroom's usefulness. A witness to this practice described it as follows in 1809:

> Among the Koryaks... it is quite common for a sober man to lie in wait for a man intoxicated with mushrooms and, when the latter urinates, to catch the urine secretly in a container and in this way to [*sic*] obtain a stimulating drink even though he has no mushrooms. Because of this curious effect, the Koryaks have the advantage of being able to prolong their ecstasy for several days with a small number of fly-agarics. Suppose, for example, that two mushrooms were needed on the first day for an ordinary intoxication; then the urine alone is enough to maintain the intoxication on the following day. On the third day the urine still has narcotic properties, and therefore one drinks some of this and at the same time swallows some fly-agaric, even if only half a mushroom; this enables him not only to maintain his intoxication but also to tap off a strong liquor on the fourth day.[33]

In other words, the psychoactive urine becomes less so with each successive urination unless supplemented by ingesting more *Amanita muscaria*. This diminishing effect, confirmed by scientific research,[34] recalls the procedure of dunking Cú Chulaind in three vats of water in order to progressively curtail his warp spasm and restore him to a state of normal consciousness. Another interesting parallel is found in the *Rig Veda*, where hymn 9.97.55 mentions three filters through which Soma must be passed to render it clarified.[35]

Also worth mentioning here is a striking description of Cú Chulaind's hair. According to one of the myths, it was "brown at the base" and "blood-red in the middle," with "a crown of golden yellow."[36] Dried caps of *Amanita muscaria* often exhibit the same three colors (see Figure 1).

Dried caps of Amanita muscaria

Shamanic Origins

The foregoing adds credence to theories that the ancient Irish Celts may have used *Amanita muscaria* as an intoxicant or in Druidic rituals. If so, this would seem to refute Wasson's claim that the Celts were one of the peoples "infected with a virulent mycophobia, coming down from prehistory"[37] and his report of finding "no mushrooms in the records that we possess of the shadowy Druids."[38] Perhaps what Wasson interpreted as Celtic mycophobia was actually a strong tabu against the casual mention of a psychoactive mushroom used exclusively in secret magic rituals. I do find it curious that Wasson does not comment on the mysterious "magic egg" (*anguinum*) which, according to Pliny the Elder, was "esteemed by the Druids and believed by them to 'ensure success in law-courts and a favourable reception by princes.'" Pliny described it as "round, and about the size of a smallish apple," with a "cartilaginous shell...pocked like the arms of a polypus [octopus]." The Druids told him that it was composed of secretions and spittle from snakes. Scholars have guessed that it may have been either a sea-urchin minus its spines or the agglomerated egg-case of a whelk.[39] To me it sounds possibly fungal in origin - perhaps a mushroom somewhat altered in appearance by Druidic art.

In any event, it is certain that the Irish bards, themselves most likely Druids, do not openly allude to any psychoactive mushrooms in the ancient myths. We have heard the opinion of Laurie and White that these myths refer to *Amanita muscaria* only symbolically in order to "communicate teachings about the sacrament's use to initiates, while maintaining a protective veil of secrecy around its identification." That may well have been the case. But they concede that Wilson's theory is another possibility; that Irish Celts may have "preserved *soma* motifs in their myths without actually continuing the use of soma - just as Christians still cherish many ancient pagan religious symbols, such as Yule logs and decorated trees at Christmas, and fertility bunnies and eggs at Easter, without understanding their original pagan content."[40] Wilson's viewpoint also seems to be supported by the fact that *A. muscaria* does not readily grow in Ireland. Laurie and White think it may have been more common there in ancient times, before the almost total deforestation of that country in the last thousand years. But if so, as they themselves admit, "there is no irrefutable archeological evidence...such as the discovery of an archaic medicine bag filled with psychoactive mushrooms" to prove that Irish Celts used *A. muscaria* or any other "psychotropic substances capable of inducing ecstatic, visionary experiences."[41]

I would add that the effects of *Amanita muscaria* are so unpredictable that the Celts had strong incentive to abandon its ritual use before settling in Ireland. The problem for them was not only that *A. muscaria*'s active ingredients vary "considerably" from mushroom to mushroom.[42] "Soil conditions and geographic and seasonal factors also affect its hallucinogenic properties."[43] Imagine the frustration of attempting to gauge the appropriate dose of local mushrooms for different people in varying regions and seasons and climates as the Celts migrated westward for thousands of miles from their point of origin! That alone would suffice to explain why the Celts may have abandoned using *A. muscaria* in favor of surrogate plants or mythic symbols such as magic food. However, my respect for the intelligence, resourcefulness and pluck of traditional shamans allows that it is possible that once they had settled in Ireland the Celts found some way to mitigate the mushroom's potentially dangerous effects. In that case what Cú Chulaind represented for the bards of ancient Ireland was not *A. muscaria*'s use in their contemporary culture but the difficulties that their Celtic ancestors experienced when using it before they came to Ireland. These difficulties may have been conflated with the memory of battles fought during the Celtic migration. For example, *The Cattle Raid of Cuailnge* (*Tàin Bó Cuailnge*), is believed to derive from a narrative version transcribed as early as the 7th century C.E. But the earliest surviving copy dates from the 11th century and appears to be "a conflation of two 9th-century texts with some extra material added by the compiler himself."[44] According to Dáithí Ó hÓgáin, who regards *The Cattle Raid of Cuailnge* as the "central, and structurally the basic, story in the [Ulster] cycle,"

> This narrative is taken to encapsulate many aspects of the culture of the ancient Ulaidh [*var.* Ulaid], portraying a warrior-aristocracy organised on the lines of a heroic society and providing an authentic picture of an Iron Age Celtic culture. The military-political situation described in the narrative was explained by a series of "pre-tales" which were put together at a quite early date in support of the *Tàin*. These "pre-tales" also preserve fragments of myth and ritual from ancient tradition, and thus the general corpus evidences several details which can be compared with what Greek and Latin writers on the Continent attribute to the Celts known to them.[45]

This reinforces the theory that Irish Celts retained in their traditions ancient memories of things that their ancestors did or saw done either during or before their migration from the Indo-European heartland. At about the same time that they started this westward migration around 2500 to 2300 B.C.E., their Aryan neighbors apparently left the same heartland and started moving southward into India. Reflecting on this process of migration and culturization, the distinguished archeologist Stuart Piggott has observed:

> More and more the archeological evidence begins to reflect the existence, over most of Europe, of a warrior aristocracy of a type familiar to us from the heroic and epic literature ranging from the Iliad to the Sagas; from the *Rig Veda* to the *Tàin Bó Cuailnge*. If we look for an early context for the structure of society already ancient in early Europe, the tripartite social grading in its various forms; the government by king, elders, and assembly; the importance of the warrior class - it fits readily within the framework of what we can infer from the early second millennium B.C. onwards.[46]

Piggott says that this earlier framework, comprising a "curious amalgam of traditions and techniques, of peoples and ideas," provided the general context from which Celtic culture emerged en route to Ireland.[47] Wasson, whose research exposed him to Piggott's ideas, sent Piggott a copy of his book *Soma* and received in return this endorsement of Wasson's fly-agaric theory in a previously unpublished letter dated 11 October 1970:

> I would say straight away that I am persuaded that you must be right. One can never arrive at mathematical certainty in such things, but I find the cumulative effect of your always level-headed and judicious arguments quite convincing. I had already thought that, whatever Soma may have been, its use in Vedic religion as an agent to induce ecstacy [sic] meant that we were, in that religion, partly in a world that was not characteristically Indo-European, but which was somehow

> linked with shamanism in its widest sense. I recently wrote a little book on the Druids, and in it had to consider whether there was a shamanistic element in Celtic religion: with Eliade, I had thought there was none, but his book set me thinking in wider terms. The probability of Finno-Ugrian elements in Sanskrit would of course give just the links needed between the two worlds.[48]

What Piggott actually says in his book *The Druids* is that the "Celtic tradition in Ireland conserved untouched archaisms in language, ideas and even prosody which have their counterparts in Sanskrit or Hittite, and we must be seeing fragments of a common heritage that goes back to the second millennium B.C."[49] His analysis of these archaisms led him to conclude that "the Irish vernacular sources, especially the hero-tales, are the product of a primitive, illiterate, heroic society with a warrior-aristocracy" which composed them in accordance with its values.[50] He also believes that certain Druidic practices of the Irish Celts suggest "a very archaic substrate of belief" reflecting, it may be, an even earlier and more "primitive" influence: Central Asian shamanism, possibly originating near the Altai Mountains which border Siberia.[51] Rutherford, too, calls attention to this region as a possible shamanic nexus for the Druids and Vedic Aryans.[52] In addition to observing that "the Brahmanic ritual drug soma...is plainly the descendant of those used by the shamans to assist in inducing the trances,"[53] he states in a footnote:

> Evidence as to whether the Druids used ritual drugs to aid trance is wholly circumstantial, coming in part from Pliny's description of the mistletoe-gathering ceremony, though the mistletoe-berry is not a hallucinogen, and partly from a folk-tradition that they extracted an opium-like substance from the poppy. It is also possible that the so-called "magic mushroom" was used for Druidic purposes.[54]

The term "magic mushroom" is usually used in reference to those of the *Conocybe*, *Psilocybe* or *Stropharia* genera, which have very different effects from *Amanita muscaria*.[55] However, Rutherford's guess is more compelling in regard to *A. muscaria*. For even if the Druids did not use the fly-agaric in their practices, the fact that it grows only in mycorrhizal relationship with conifer and birch trees makes it similar in one important respect to mistletoe: the latter is a parasitic plant which grows only on trees. According to Pliny, the Druids considered "nothing more sacred than mistletoe and the tree that it grows on, so long as it is an oak." Beneath such trees, he said, they held religious feasts and sacrificed "with prayers to the god to render [their] offering propitious."[56] It thus seems feasible to me that the Druids used mistletoe in these rituals as a symbolic surrogate for *A. muscaria*.

Conclusion: The Soma Connection

A similar process occurred, I believe, in the Vedic religion with Soma. However, this change would have happened more slowly because of different circumstances. Migrating westward from their Indo-European heartland, the Celts encountered a wider variety of indigenous cultures than the Aryans did heading southward into India. Each successive conquest of these cultures presumably altered the Celtic religion through a process of syncretic transformation, just as the religion of the Aryans was changed by local Indian religions. Since it took the Celts far longer to reach Ireland (apparently the first of them arrived there in the sixth or fifth century B.C.E.),[57] it is easy to see why the Irish myths differ so markedly from Vedic hymns to Soma while yet bearing what Mac Cana calls "the unambiguous marks of a common origin."[58]

One of these marks, I believe, is the Indic god Rudra who figures in some of the earliest Vedic hymns. Clark Heinrich has convincingly explored the possibility that Rudra was initially identified with Soma.[59] I would add that Rudra's attributes remind me of Cú Chulaind. This is clearest in *Rig Veda* 2.33, the "Hymn to Rudra," which acknowledges his power to bestow special favors on those who worship him properly and to injure or at least withhold his favors from those who do not.[60] The first of the favors solicited is "the vision of the sun" (2.33.1). Next come prayers for protection, progeny and health or healing. As with Cú Chulaind, Rudra's powers are potentially useful in battle. He is asked to ensure that "our warriors on horseback remain unscathed" (2.33.1) and to fend off "all assaults of injury" (2.33.3). But also like Cú Chulaind, Rudra sometimes shows a tendency to injure those he normally protects. Helplessly acknowledging that Rudra's "shattering power" and "vast strength" (2.33.10) make him "like unto a beast" that is "fearful and strong, all ready for the kill," his petitioners pray to be spared the effects of his "fearful wrath" (2.33.5) and "great ill-will" (2.33.14). Their exhortation, "lay another low - not us!" (2.33.11), sounds identical to what we would expect to hear Cú

Chulaind's fellow warriors tell him.

The Vedic priests apparently tried hard to accommodate Rudra's capricious behavior. I believe this accounts for the complex stipulations of their Soma ceremony. If the mushroom itself had an unpredictable potency which threatened unpleasant experiences, there was only one recourse: all other variables had to be strictly controlled. This is consistent with an observation made by Andrew Weil:

> One valuable influence of ritual is to minimize the disruptive potential of [psychoactive] drugs and maximize their useful effects. All drugs have this ambivalent potential: they can trigger positive, helpful reactions or unpleasant and unhelpful ones....Ritual in the use of drugs works to curb the development of panic reactions by standardizing expectation in a positive direction. It helps define reasons for taking psychoactive substances in the first place, and gives participants a framework of order through which to interpret their experience.[61]

In the Vedic Soma ritual, techniques were developed to standardize both the preparation of the sacrament and the constitutional receptivity of those who ingested it. The Soma plant was pressed to release its juice, a tawny liquid. Then this juice was mixed with milk or curds. Perhaps numerous *Amanita muscaria* mushrooms which had been harvested at different times in different locations were combined at this stage of the ritual, in order to average out their diverse potencies. The Soma drinkers prepared themselves to imbibe the concoction by fasting and chanting the relevant Vedic hymns for several days. This would have standardized the body biochemistry of different individuals as much as possible, while also adjusting their minds to provide an appropriate "framework of order" for enlightenment. Yet despite these precautions, they sometimes, unpredictably, encountered Rudra's devastating wrath and eventually tired of it. Then they, like their cousins the Celts did at least temporarily, gave up using *A. muscaria* in favor of non-psychoactive alternatives that were dependably transmissible from adepts to initiates - most notably the esoteric system of philosophy laid out in the Upanishads. At that point Rudra-Soma joined Cú Chulaind as a literary vestige of the Indo-European heartland.

Mesoamerica's 'Dark' Image

No rite evokes so many stereotypes of 'pagan darkness' as human sacrifice. For seven thousand years[1] in every corner of Mesoamerica,[2] thousands of people were decapitated, stoned, drowned, burned, crushed to death or cut open to have their living hearts removed as part and parcel of religious festivals. This paper concentrates on the grandest manifestation of this tradition: Aztec human sacrifice. Necessarily, we will also ponder its broader Mesoamerican context.

Many Spanish estimates of the frequency of Aztec human sacrifice are now considered exaggerated.[3] Nevertheless, early sources (namely, Diaz, Duran, Sahagun, and Cortes) give almost identical figures: each Aztec temple-complex dispatched two to six victims every twenty days. Thus, each Aztec town, 'even the most wretched villages',[4] conducted forty to a hundred and twenty killings annually.[5] For cities and special events such as centenaries and royal funerals, the figure moved into the hundreds or thousands. The inauguration of the Templo Mayor consumed twenty thousand lives.[6]

Such slaughter amounts to the greatest ritual carnage in human history. Consequently, Mesoamerica is almost a resident alien in the world of human cultures. As Jacquetta Hawkes notes, Mesoamerican culture, and particularly its religion, appears unusually dark and is considered

> strange and remote... brutal and sinister... threatening and perverse... uninhibited in displaying... sadism... [and as] manifest[ing]... little of the counterbalancing virtues of humanity.[7]

So pervasive is this 'dark' image that Michael Hamer has called it an 'open wound' on the flank of scholarship.[8]

Explaining Mesoamerican/Aztec 'Darkness'

Attempts to explain this 'darkness' have, quite simply, failed. The most common explanation - that the Aztecs and their kin were savage, immoral or amoral[9] - is untenable in the face of the growing acknowledgement of the complexity of Aztec sciences, the delicate aesthetics of their literature, and the balanced nature of their ethico-legal codes. The Aztecs had strict laws against murder. Sacrificing priests had to be 'careful, helpful, never hurt anyone [and remain] compassionate towards others ...[and] loving'.[10]

Faced with such paradoxes, Laurette Sejourne, Irene Nicholson and Miguel León-Portilla have promoted the notion that Aztec spirituality was 'betrayed in its most sacred essence'[11] and was corrupted, in its 'darkest hour'[12] into human sacrifice for 'vicious totalitarian ends'.[13] Apart from the inherent racism of such a view (consigning much of Mesoamerican history to mere 'ignorance... decadence'),[14] this 'betrayal' theory is confounded by archaeological discoveries and improved readings of Mayan glyphics, which have established that mass sacrifice had always been a part of Mesoamerican society.

Other hypotheses suggest environmental or cultural deficiencies. Michael Harner and Marvin Harris, for example, view the rite as a means of procuring protein and 'essential amino acids' since victims' bodies were sometimes consumed.[15] J.M Ingham, Barbara Price, David Carrasco and others claim that the Aztec elite developed mass sacrifices in order to terrorize their populace and enemy states.[16] Peter Furst and Gordon Wasson assert that Mesoamerican religion is a remnant of Upper Paleolithic psychedelic shamanism; the implication of their argument being presumably that drug-induced confusion between hallucination and reality created sufficient hysteria for murder to be instituted as a sacred rite.[17]

All of these theories have serious flaws. Runn has found that the early Mexicans had plenty of protein sources[18] and only ate tiny slivers of human flesh in rare, restricted rites 'as a form of communion'.[19] Likewise, R. Hilton and Inga Clendinnen have debunked the 'oppression' argument, finding little evidence of Mesoamerican kingdoms being unusually totalitarian,[20] and that 'mere oppression' could not explain 'how the trick worked'.[21] Finally, it now seems Mesoamericans despised and tightly controlled the use of narcotics and in fact inflicted far harsher punishments than the modern West.[22]

The Light of Darkness?

Thus, the puzzle remains; the rite is 'still undeciphered'.[23] Perhaps the reason for this mystery is that there has been little effort made to reconstruct what sacrificial death may have actually meant to its practitioners. In this paper, I weave together filaments of what the Aztecs themselves said and thought about human sacrifice. Their 'voice' will be their art and literature, especially their rich stock of poetry and prose, which was collected soon after the Conquest by Bernardino de Sahagun, Diego Duran, Motolinia and others, as well as the Aztec responses recorded in Conquistadors' records and ethnographic studies. In assembling this reconstruction, I am guided by Frederick Streng's firm belief that every culture has 'problematic states' which it seeks to remedy by developing a path of 'ultimate transformation'; that is: a set of personal and collective/cultural practices.[24] Hence, the view we are taking here is that of human sacrifice as a path of 'ultimate transformation'.

Dark Deeds or 'Great Deeds'?

The first issue we need confront in order to establish a 'Strengian perspective' is whether the Aztecs considered their rite loathsome or honourable. It is often assumed that Aztec human sacrifice was the lot of poor or 'disposable' people such as commoners or foreigners. However, the earliest accounts concur that virtually all children slain in these rites were locals of noble lineage, *offered by their own parents*.[25] Likewise, adult victims rarely seem to have been foreigners. In 1454, the Aztec government forbade the slaying of captives from distant lands at their temples.[26] Duran's informants told him that sacrifices were '*nearly always*... friends of the [Royal] House'[27] (namely: warriors) and were often of considerable status, as well as coming from neighbouring city-states and allies who shared the same culture and creed.

Why this might be seems to have a lot to do with the nature of Mesoamerican warfare. Most people were captured rather than slain in war since the aim was 'not to slay, to do no harm to man or woman... but to feed the idol'.[28] *Xochiyaoyotl* ('flowery wars') - monthly ceremonial affrays between allies and neighbouring city-states - were the usual source of sacrificial victims who included priests and a high proportion of noblemen.[29] In other words, the 'victim-procuring wars' were prestigious affairs through which local priests and lords stood a good chance of becoming sacrificial victims; as the Aztec Emperor reminded his victims, 'today for you, tomorrow for me'.[30] Certainly, the sacrifice of neighbouring kings was common enough for Classic Mayan monarchs to actually take on the title of those they captured.[31]

These factors meant that there were many illustrious role-models for captives/soon-to-be-victims to emulate. The Tlaxcalcan captain Tlahuicoli, for example, who was captured and put in command of a major military expedition demanded to die in gladiatorial sacrifice *despite* being granted his freedom.[32] Likewise, the anonymous prince in the Mayan *Tale of Rabinal* escapes his captors to bid goodbye to his homeland, but nevertheless nobly returns to his enemy's temple to meet his ritual end.[33]

Thus, it seems sacrificial death was considered a glorious end. When Spaniards criticised the rite, Aztec informants made 'indifferent or sarcastic remarks'[34] and were equally quick to ridicule the 'weakness of the Christians'.[35] Duran notes that his informants applauded

> the sacrifice of human beings... [as] *the honoured oblation of great lords and noblemen. They remember these things and tell of them as if they had been great deeds*.[36]

Sacrifices, as the 'main act' of huge feasts and festivals, were indeed hailed as 'great deeds'. Victims usually died 'centre-stage' amidst the full splendour of dancing troupes, orchestras, elaborate costumes and decorations, carpets of flowers, crowds of thousands and all the assembled élite.

The captive/victim was the Aztec equivalent of a celebrity or rock star; they were 'sighed for' and 'longed for' by the audience.[37] Their deaths merited a public announcement and their names were immortalised in the local 'roll of honour'. Commemorated in songs, poems and epics, the deceased were further honoured by the *euillotl* (human effigies) their relatives had constructed from pine log torches and decorated with paper wings and jacket. These effigies were burnt in memory of the victim for two days, and they took pride of place in the heart of town. Indeed, sacrifices were made to a *euillotl*, as though to a god.[38]

Honour and Compliance in Aztec Human Sacrifice

The prestige of sacrificial and war-related death explains why the victims Cortes and Alvarado freed 'indignantly rejected [the] offer of release and *demanded to be sacrificed*.'[39] It may also explain why Diaz found that the Aztecs '...cared nothing for death in battle... [and] came at us like mad dogs'.[40] Hernan Cortez described an actual hunger for death, noting that the Aztecs 'seemed *determined to perish* more than any race of man known before.'[41] Purportedly, victims sang and danced to their deaths 'with great joy and gladness'.[42] Others walked up 'purely of their own will',[43] and the poets chanted *otiquittaco quinequi moyollo yehua itzmiquitla*: 'You came to see it... your heart desires it: it was death by the obsidian blade!'.[44]

But not every victim could have craved 'death by the obsidian blade'. Even Aztec accounts mention some who wept, 'faltered... weakened' or lost control of their bowels.[45] Amazingly though, these were such a minority that they were viewed as a bad omen[46] and a *tetlazolmictiliztli* ('insult to the gods').[47] A 'weak' victim was hurriedly taken aside and slain amidst the congregation's sarcastic jeers of 'he quite acquitted himself as a man'.[48]

What we can glean from all this is that the sacrificial role entailed a great deal of social expectation and acquiescence. Unwilling victims were sometimes passed over in favour of more willing ones.[49] Key roles were reserved for those 'without [moral] defects... of good understanding ... good mannered'.[50] For many rites, the victim had such a quantity of prescribed duties that the festival would have failed without his or her willing compliance. Victims were expected to bless children, greet and cheer passers-by, hear people's petitions to the gods, visit people in their homes, give discourses and lead sacred songs, processions and dances.[51] Clendinnen and Brundage felt only a few had this kind of role, but the *Florentine Codex* and Duran make no such distinctions, stating that

> those who had to die performed many *ceremonies*... [and] these [pre-sacrificial] rites were performed in the case of all the prisoners, each in turn.[52]

Dark, Dead Gods

When Spanish friars demanded that the Aztecs destroy their gods, the priests replied, enigmatically, 'our gods are *already dead*'.[53]

Mesoamerican divinities are indeed mostly 'dark' or 'dead'. According to Richard Haly, the Aztec High God was basically a 'bone god', existing as the 'marrow' or 'dead shadow' behind all the gods.[54] Certainly, most Mexican deities are skeletons, skull-headed or severed heads and dismembered corpses.

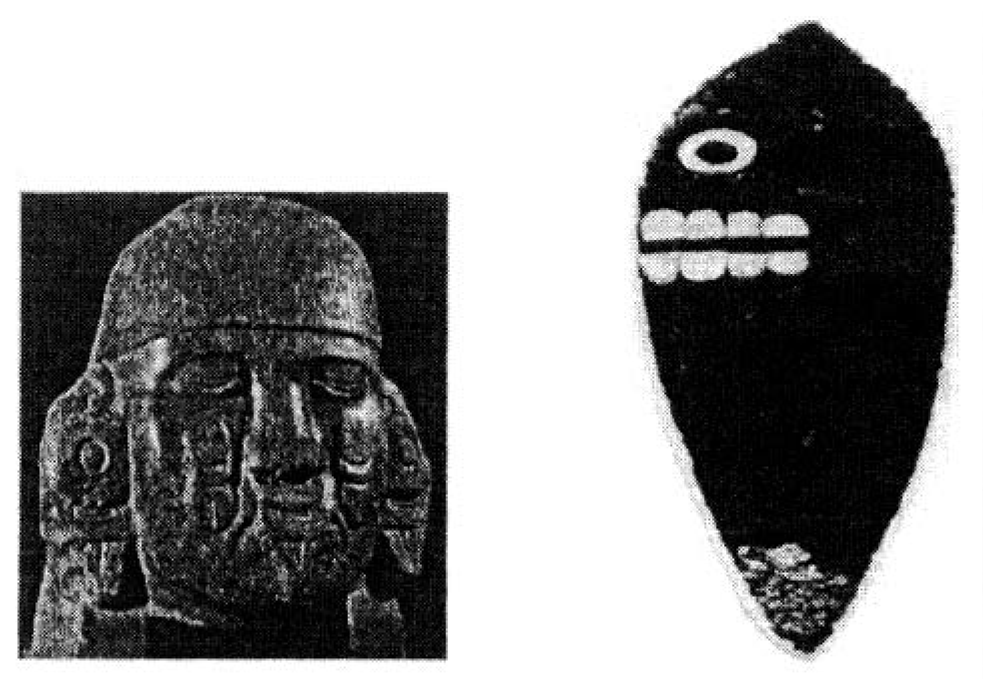

Figure 1: Dead, dark gods: God as a severed head (the moon goddess) and a hungry knife.

They are blackness and annihilation in one form or another, squatting in dimly lit or pitch black shrines.[55] These *tezcatl* (obsidian - black volcanic glass - mirrors) bear names such as 'Shadow', 'Black One', 'the Night' and 'Naught' (*Mahuq*'*utah*).[56] They are cosmic vortexes or vacuums; carnivores who devour warriors and maul their hearts; natural disasters; 'the Causer and Giver of aliments'; 'the Sacrificer', 'the Enemy', 'the Box of Death' (*Micapetlacalli*) and 'the Mother of the Inferno'[57] who 'kills... [whoever] wages war against us'.[58] As one poet sighed, 'He [the High God] too, came to cut off my life on earth'.[59]

Through these terrible gods, we, as individuals, 'disappear' into *Toanpopolihuiyan*: 'the Common House, where we lose ourselves' and 'become as one'.[60] Indeed, in this regard, this sinister pantheon is, in its extinguishing qualities, almost reminiscent of certain Buddhist concepts.[61] Sacrificial hymns collected by Bernardino de Sahagun have the victim singing that 'in a coffer of jade [the 'eagle vessel' that held human hearts] *I burn myself up*',[62] and that all 'will for ever end',[63] or, even more intriguingly, 'our death was *utterly ended*'.[64]

The Glory of Dying Well

Such imagery suggests that sacrificial death was believed to dissolve and purify in some absolute sense; certainly, it was claimed that death brought theosis wherein to die is to 'become God' (*teo-ti*).[65] Death contains all the highest joys, the highest truths and the highest states: 'peace and happiness are there' ; 'all is eternal there' ; there, 'the answer will be known (there)'.[66]

Regarding earthly life, by way of contrast, we hear it declared that:

> It is not true, no it is not true
> That we came to live on the earth
> We came here only to dream
> We came here only to sleep.[67]

Earth, we are told by a variety of Aztec poets, is not the place to accomplish things since 'our [real] home' lies in 'the Land of the Fleshless.'[68]

As might be expected with this kind of world-view, *how* one died was extremely important. The Aztecs meticulously organised death into types and levels. Passing away at home constituted the lowest end of the scale. 'A good death' was braver or more torturous. Those who died sacrificially, or in war or childbirth, procured the second-highest heaven (death in infancy formed the highest). Such fortunate souls are 'the God-dead' (*Teomicqui*) who

> go pure... live *hard by, nigh unto* the Sun... [who] always forever... rejoice... [since] the House of the Sun is... a place of joy.[69]

Miguel León-Portilla has shown that references to being 'joined to/at the side/nigh unto' this or that deity refers to 'Twinship' with a Deity which counts as the highest possible state.[70]

Cutting Portals through the Impenetrable Wall

Sacrificial death was also thought to provide 'an opening'[71] (what the Yaqui of northwest Mexico call 'the crack between the worlds') or portal into the highest Reality, which was hidden by an otherwise impenetrable wall. Native picture books such as *Codex Nuttall* show the heavens as a solid block above the world, occasionally punctured by a 'wound' through which deities could descend.

Mesoamericans required bloody 'openings' into the heavens because, as their religious songs complain, the gods are often 'stony'; that is: inexorable, silent.[72] Perforating the body, even to the point of death, was a way to 'perforate, penetrate' the 'mount' of God; indeed, this is the image used in some sacrificial hymns.[73] From infancy onwards, as Patricia Anawalt has shown, Aztecs performed ritual perforation known as *maceualiztli/tlaxoquixtiliztli*, 'good deeds', 'blood penance' which entailed piercing the ears, tongue, forearms and legs and drawing straws or ropes through the wounds. Such self-tortures were at times fatal, but were viewed as the best means of attaining spiritual boons and spiritual experiences ('vision serpents'). The practice was touted as our 'salvation'.[74]

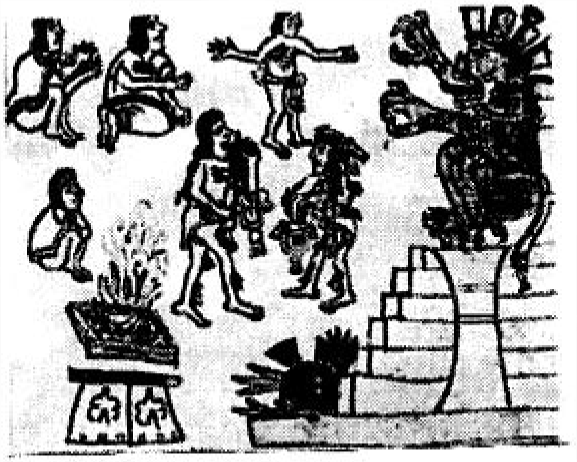

Figure 2: Tlaxoquixtiliztli (autosacrifice).[75]

Heart-Extraction: Returning the Divine Fragment

The chilling nature of Aztec heart-extraction may need to be read in the context of this culture that viewed excruciating (sometimes fatal) wounds as a path to the gods. The human offering was not enduring something he or she had no previous experience of. Nor did he or she suffer alone, since before and during human sacrifice, victims, priests and congregations habitually 'created openings' by perforating and bleeding themselves.[76]

The rite of ripping out victims' living hearts created the ultimate 'opening' through which to access the gods. The physical heart-soul (*tona*) was considered both the seat of the individual and a fragment of the Sun's heat (*istli*), and indeed the Sun itself was also considered a heart-soul, 'round, hot, pulsating'.[77] This divine fragment was seen as 'entombed' in our body and ruined by base desires.

> Where is your heart?
> You give your heart to each thing in turn.
> Carrying, you do not carry it...
> You destroy your heart on earth.[78]

Heart-extraction was evidently believed to liberate one's *istli* and reunite it with the Sun.

Aztec *Codex Magliabechiano*, Folio 70 depicts a victim's transformed heart flying Sunward on a trail of blood:

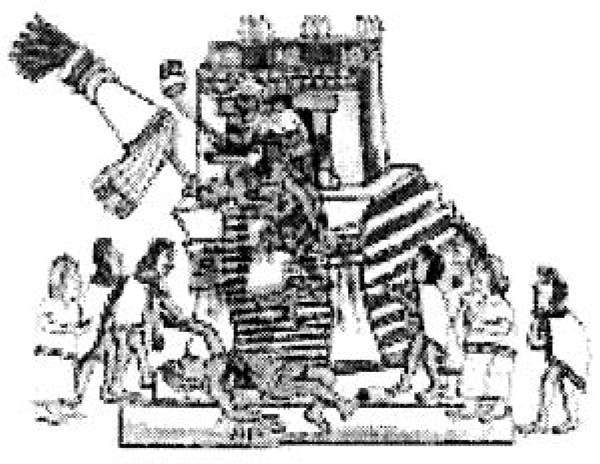

Figure 3: Emancipating the heart.[79]

The scene echoes a verse in *Codex Matritensis*:

> My heart rises;
> I fix my eyes upon You,
> next to You, beside You,
> O Giver of Life![80]

As noted earlier, 'next to You, beside You' refers to the highest possible spiritual attainment: the mystical state of Twinship with the deity. Likewise, 'rising' seems to be a metaphor for spiritual ascent. Images of heart-raising and heart-burning pervade Aztec poetry and Aztec heart-extraction. In sacrificial rites, the extracted heart was raised several times as its fumes (*istli*, 'heat') wafted upwards; additionally, it was often burnt to aid its ascent. Even today, Chamula Mayans refer to the 'best' (that is, most noble) heart as 'burning' or 'rising', while a heart on the point of death is described as 'very hot'.[81] The Aztec verb *tle'ca.uia* ('to burn', 'to set on fire') is, moreover, etymologically related to the verb *tle'cauia* ('to raise' or 'take up').[82] The end result was the notion of a *Yolleteotl*, a 'God-heart' which is apparently shown (wearing a little God-mask) in *Codex Laud*:

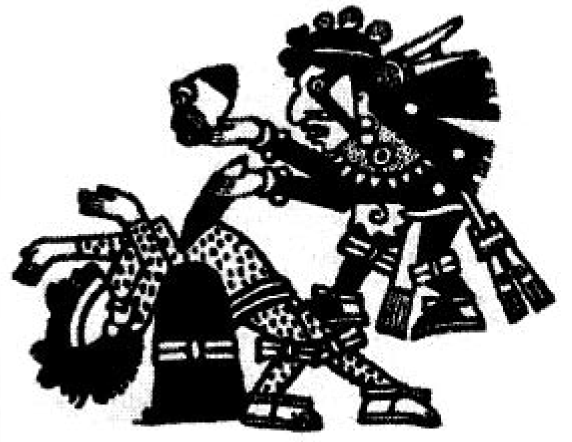

Figure 4: *Yolleteotl* (God-heart), wearing a Divine mask.[83]

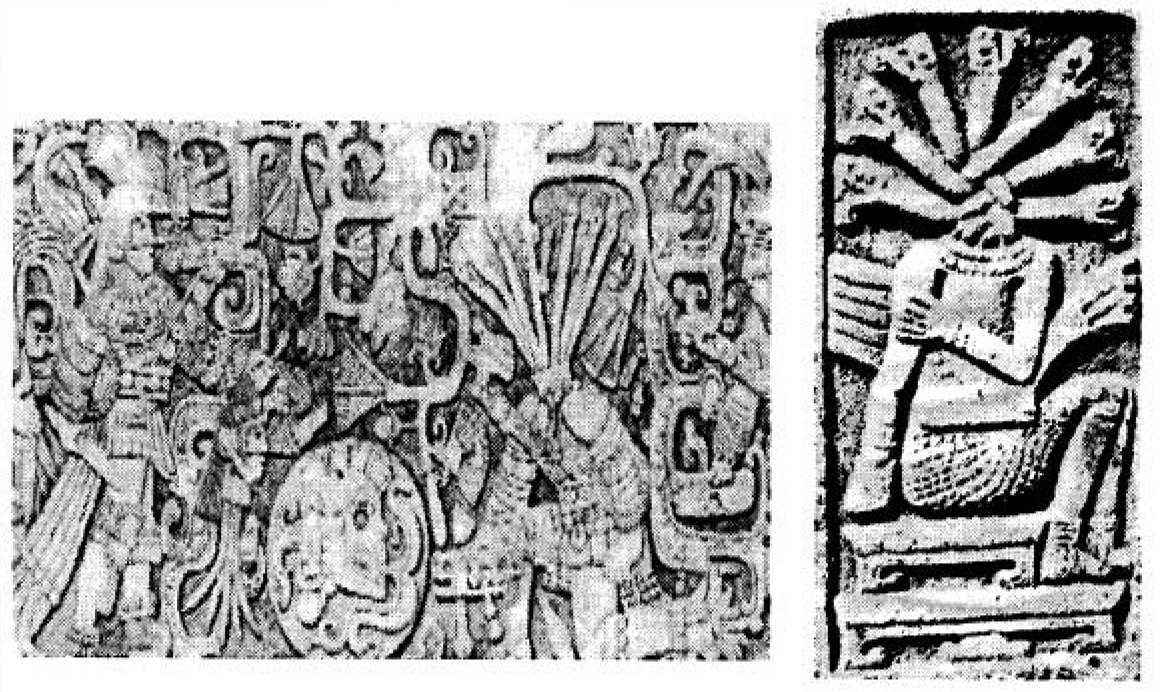
Decapitation: Untangling the Soul?

Decapitation was undoubtedly another 'portal' of emancipation, being the second principal method of Aztec sacrifice. Native rationales for the act have been lost, but are certainly ancient. The centrepiece of the 9th and 10th century ball courts at both Tajin (on the Gulf Coast) and Chichen Itza is a series of reliefs depicting a key player being decapitated. From his neck, he sprouts *seven* serpents and vegetable vines which push back the amazed participants:



Figures 5 & 6: Decapitated ball players sprouting seven serpents and vines.[84]

Although we do not know precisely what this represents, Alan Sandstrom has found that contemporary Nahua (Aztecs) believe that each person has a seven-segmented *tonali* ('energy' or 'soul') which is viewed as a series of 'serpents' 'twisted' throughout the body.[85] Possibly the ball court reliefs depict the release and 'untwisting' of *tonali* through decapitation, perhaps even as a means of 'untangling' the knotted earth, as Ceclia Klein's study of the carvings suggests.[86]

Error and Atonement

Human sacrifice was also evidently a vehicle for atoning one's own, as well as, others' wrongs. According to the Mayan *Chilam Balam*, one woman, as she prepared herself for the sacrificial altar 'took upon herself the guilt of the locusts that have destroyed all that the people sowed'.[87] The Aztecs described victims who were 'sent [that is: killed] to plead for us,' or 'consecrated to annul all sin.'[88] In one Aztec poem, a warrior-victim announces that 'I embrace mankind ... I give myself to the community'.[89]

Death might seem a severe atonement, but in Aztec society, the slightest *tlatlacolli* ('sin' or 'insult') was a deadly serious matter. *Tlatlacolli* itself was viewed as an extremely dangerous force. Even a humble villager could, through an immoral act, unleash widespread natural disasters. Chamula Maya still blame plagues and droughts on the sins of individual villagers.[90] If an adulterer were to enter a house, Aztecs believed, all turkey chicks would perish from *tlazomiquiztli* ('filth-death').[91] For this reason, virtually every error incurred either the death sentence, life-threatening beatings, or permanent exile. If a ritual dancer made a wrong step; if a novice priest accidentally allowed a doughball offering to roll away, they were dragged off and executed.[92]

Although if such a person were not executed, they would probably have killed themselves anyway, for the Aztecs far outpaced their Catholic conquerors when it came to feeling burdened by guilt. Wrongdoers in the Aztec world would loudly proclaim that they were 'of mud, of earth'. They would physically and mentally torture themselves with *nonecoliloca* ('the hatred which I feel for myself') by slitting their tongues for vices of speech or their ears for vices of listening.[93] In classic Nahuatl (the Aztec language) the verbal form *ni-c-yecoa*, 'I sin', is closely related to *ni-c-ye.coa*, 'I finish it': error, quite literally, 'finishes' or 'ruins' everything.[94] There was a logical progression from the severity of sin through to the 'penance' of human sacrifice; indeed, the Nahuatl words for 'penance' and 'human sacrifice' were interchangeable.[95] Mere tears and blood washed away 'vile qualities' to some extent, but nevertheless even

> for a slight [sin they] hanged themselves, or threw themselves down precipices, or put an end to themselves by abstinence.[96]

Slavery and Capital Punishment

Such 'fatal atonement' was also visited upon slaves who were the only other main group from which human sacrifices were drawn,[97] and indeed it is no coincidence that Aztec 'sinners' actually described themselves as 'slaves' since enslavement was the punishment for all smaller misdeeds and debt. It was not a permanent class, and seems to have been composed largely of local people;[98] anyone could fall into (and out of) it.[99] However, if one continued to err, then slavery guaranteed a sacrificial end. Miscreant slaves were sold at market to whatever trade or craft guilds required someone to represent (and hence die as) their patron deity at the next festival.[100] So, sacrificial death sometimes blended capital punishment with personal atonement: 'fallen' persons atoned for (and were punished for) their crimes by dying for the gods. Some slave-deaths of this type were followed by an Aztec priest delivering a sermon about 'downfall' and what a real danger it was it was since those who 'esteemed... sweetness... ended in misery'.[101]

'The Road to Our Downfall': Humiliation-unto-Death

Such attitudes hint at an entire theology centred around 'the road to our downfall' as the Aztecs termed it, and this theology may well have provided the format and overall context for human sacrifice. Certainly one of the key myths of Mesoamerica is such a story. It concerns Quetzalcoatl Topiltzin, the epitome of an ascetic, celibate priest-king who, after decades of perfect conduct, agrees to imbibing a drink which he is told will make him 'compassionate' and help him to 'think of [or perhaps, in modern parlance, 'come to terms with'] death'.[102] Intoxicated, Quetzalcoatl commits incest with his sister, but then, overcome with remorse, he quits his throne. He buries and destroys his possessions and wanders about aimlessly, enduring hardships and humiliations. Finally (at least according to some versions of the tale), Quetzalcoatl immolates himself in a bonfire, thereby becoming the Morning Star. Significantly, Quetzalcoatl's 'humiliation onto death' is viewed as *necessary*; as the myth (*Leyenda de Los Soles*) itself explains,

> he [Quetzalcoatl] fell ... in order that he might strive, in order that the Dawn might come.[103]

Implied in this theme of 'necessary humiliation' is a warning against pride, and indeed pride was the chief topic of Mesoamerican homilies. Priests and Lords were constantly cautioned to 'humble' and 'humiliate' themselves through set 'Humiliations' (meaning self-sacrifices).[104] Thus, it is of little surprise that 'necessary humiliation' is a theme of Aztec human sacrifice. Most captives were kept for weeks - sometimes a year - before being slain. They initially lived a regal but religious existence chanting, fasting and holding vigils - rather similarly to Quetzalcoatl. Then, again much like Quetzalcoatl, they were feted: they were given 'pleasure girls' and intoxicants. After their 'downfall', they again emulated Quetzalcoatl by giving away and burying everything they owned. Finally, naked like infants (wearing only a paper loincloth), they met their deaths.

The Great Rebirth

This dressing like an infant suggests a connection with the Aztec emphasis on child-sacrifice. It was said that 'in the time of childhood, still in the time of purity, the good death is merited'.[105] As has already been noted, those who died in infancy occupied the highest heaven, suggesting to dress like a child was not simply a humiliation, but rather was also an allusion to seeking the highest heaven, to being 'reborn' through death. A large number of the 'sagely discourses' (which were a standard part of Aztec upbringing) bemoan the fact that our 'jade' (hearts or souls) were 'glowing' at birth and in infancy, but then grow 'cold,' 'enshrouded' and 'twisted' as we age.[106] Evidently human sacrifice was considered a vehicle for recapturing this lost (childhood) purity; certainly human sacrifice was sometimes referred to as 'birth'.[107] The captive is known as the 'child, son' of his captors, and inasmuch as he sings, throughout the sacrifice, 'my life shall revive... my heart will be refreshed', he hopes to recapture this lost childhood purity.[108] Indeed, in gladiatorial sacrifice, the victim is even tied by an umbilical-like 'sustenance rope'[109] which runs from his waist to a 'birth canal' (a hole in a stone).

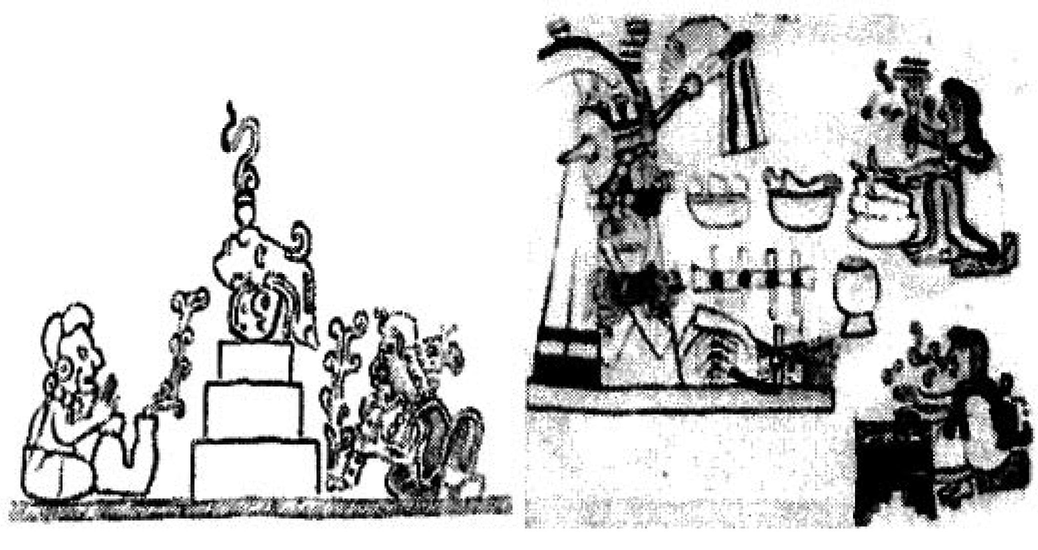
Dying as God: Becoming by Enacting

Aztec texts frequently refer to human sacrifice as *neteotoquiliztli*, 'the desire to be regarded as a god'.[110] Many rites consisted of victims taking on the paraphernalia, habits and attributes of the god or goddess whom they were dying as. This was known as being an *ixiptla*, becoming the god's representative or image. Interestingly, Aztec texts do not differentiate between human *ixiptla* and wooden or stone idols.[111] In fact, so elaborately costumed and painted were human *ixiptla* that even the congregation was unsure which were human and which were stone or wood.

To understand the significance of this, we need to digress a little into Mesoamerican concepts of divinity. Mesoamericans viewed deities as multiple yet One.[112] Rather like an actor (the Mayan term for god, *bacab*, actually meant 'clown, actor'),[113] gods usually wore masks, changing costumes and personas as the need arose, constantly transforming into each other and into a wide range of objects.[114] Their fluidity was such that the actual *appearance* or *face* of the God was a great mystery. Even the highest Mexican idols - those occupying the lofty pyramid-temples - were simply featureless lumps of dough over which clothes and precious masks were placed, and they were further hidden from view by bundled wrappings and veils.[115]

As a result, Aztec literature constantly speaks of a yearning to see the God's 'real' face and create a true 'face' for one's self.[116] In death, we are told that we will finally see God's face and achieve our own 'face'.[117] When a victim appeared in full regalia before the congregation, it was said that the divinity had been given 'human form': the god now had an *ixitli* (face),[118] since originally, as the sacrificial hymn of Cihuacoatl declares, 'Eagle feathers are no mask, for he rises *unmasked*'.[119]

All the native and Spanish sources on Aztec human sacrifice make it clear that victims were believed to attain full identity with the gods by dying as gods. Sahagun and Duran describe them being 'worshipped... as the deity'[120] or 'as though they had been gods'[121] (-the original Nahuatl term being *nicnoteoti'tzinca*, literally, 'I consider him a god').[122] Even whilst still alive, victims were honoured, hallowed and addressed (like gods) as 'Lord' and 'Lady'.[123] Posthumously, their remains were treated as actual relics of the gods which explains why victims' skulls, bones and skin were often painted, bleached, stored and displayed, or else used as ritual masks and oracles. Diego Duran's informants told him that whoever wore a victim's skin considered himself 'divine'.[124] The Mayan *Codex Dresden* and the Aztec *Codex Magliabechiano* depict victims' heads being worshipped and given food offerings.



Figures 7 & 8: Worshipping victims' severed heads.[125]

The Eternal Sacrifice

Some years after the Conquest, a body of Spanish Franciscans confronted the remaining Aztec priesthood and demanded - under threat of death - that they desist from their murderous practices. The Aztec priests conferred on the matter and boldly gave this defence:

> *Life* is because of the gods; with *their sacrifice* they gave us life... they produce our sustenance... [and] all which nourishes life.[126]

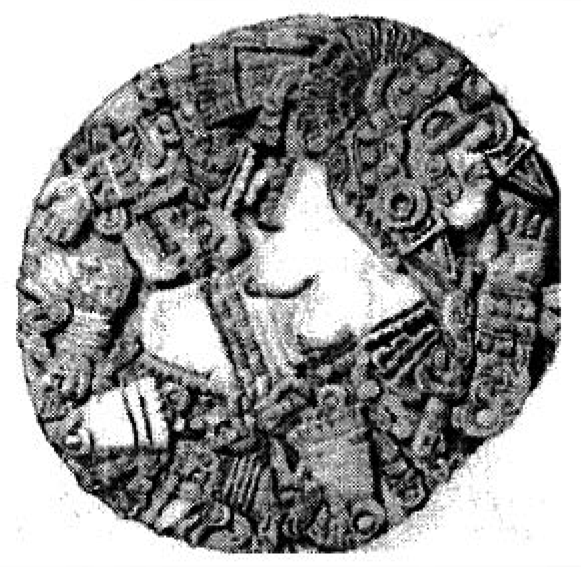


Figure 9: Large sculpture of the dismembered corpse of the Moon goddess, which stood in front of the Aztecs' Great Temple in today's Mexico City. Each severed limb is shown as Divine, wearing a God mask. Many Aztec sculptures and illustrations depicted the shattered or sacrificed bodies of the gods.

What the Aztec priests were referring to was a central Mesoamerican belief that a great on-going sacrifice sustains the universe. Everything is *tonacayotl*, the 'spiritual flesh-hood' or 'bodily (sacrificial) presence' of the gods on earth. Everything - the earth, crops, the moon, stars and people - springs from the severed or buried bodies, fingers, blood or heads of sacrificed gods.[127]

Dawn is the sun daily igniting itself for our sake; and then, crackling and screaming its way across the sky, the sun gives us sunset by smoldering in its own blood and embers.[128] It tears out its left eye (according to the Mayans) so that we will not be bothered by too much light at night; hence, the moon is the sun's hollow left eye socket.[129]

Our very existence, it was felt, was owed to this process: humanity is known as *macehuale*, 'the dead brought back to life through penance'.[130] The Earth Goddess *becomes* 'our food' so that we will not 'die of hunger'.[131] Daily, we till and eat the Earth Goddess's 'flesh' (soil and crops), build with her 'bones' (stones), and drink her 'blood' (water).[132] In several sacrificial rites, this was emphasized by eating grain images of the gods and declaring '*nicteocua*', 'I eat God'.[133]

Debt and Offerings

A strong sense of indebtedness arose from this worldview. Compared to the eternal sacrifice of the gods, human offerings were just a 'humble present',[134] a *nextlahualli* ('a debt', or 'tribute paid'), and indeed *nextlahualli* was a commonly used metaphor for human sacrifice.[135] Monaghan sees this encapsulated in the term *nchiso yu'uva* which was borrowed from the Aztecs' neighbours, the Nuyou Mixtec.[136] *Nchiso yu'uva* literally means a 'contract with the Earth' which involves giving life for life, on the basis of the understanding that one thing - and hence, everything - only lives by killing something else.

> We live here on the Earth [the dancer stomps the ground]
> We are all fruits of the Earth.
> The Earth sustains us...
> We eat of the earth
> *and the Earth eats us.*[137]

The modern Nahua shaman Aurelio puts it another way: 'everything in our lives is a *gift*';[138] nothing comes to us for free [edit. rem. - a bit of contradiction, since gift is exactly for free; in polish lang.: gift = *dar* and *dar*mo means for free and also *darmowy* (masc. sing.); where *dar mowy* means gift of speech]. Even under the threat of execution, Mesoamericans insisted that they *must* '*pay the debt* for [the gods'] bringing rain': if things are not paid for, a disastrous cosmic imbalance results.[139] Thus, rather than being an anomaly, human sacrifice was perceived as a natural obligation and so part of a mechanical tit-for-tat. The complex rites of kings and priests with its self-tortures and sacrifices were believed to 'set the people free' and 'protect the people',[140] whereas the victim simply 'gave her service'[141] and 'fulfil[led]' his 'duty'.[142]

Human sacrifice was, in this sense, the 'cherry' on top of a whole pile of offerings through which the Aztecs sought to repay their debt to the gods. They 'gladly parted'[143] with everything, happily burying, smashing, slaying and sinking vast quantities of quail, rabbits, dogs, feathers, flowers, insects, beans, grains, paper, rubber and treasures as sacrifices.[144] Even the 'stage' for human sacrifice, the massive temple-pyramids, were offering mounds crammed with treasures, grains, soil and human and animal sacrifices that were buried as gifts to the deities.[145] Adorned with the land's finest art, treasure and victims, temples themselves became offerings which were buried under new structures every eight or fifty-two years.

Despite two centuries of scholarship, many cultures continue to be dismissed as primitive and savage for having practised some form of human sacrifice. The worlds of the Celts, the Norse, the Asante, the early Peruvians and Hawaiians are mostly portrayed as dark and deluded, inhabited by ignorant, superstitious people, led by wicked priests. This is an insult to the sophistication of these cultures and their respective spiritualities. Highly urbane societies - indeed, much of the world - has practised human sacrifice at one time or another. The rite was part and parcel of the Kālī cult and Saivite Hinduism well into the 1830s (until British authorities stamped it out),[146] although modern Saivites now either deny or else completely ignore this heritage. As strange as sacrificial creeds might seem to us today, we need not look too far for modern parallels such as Kamikaze pilots or suicide bombers.

The beauty of Frederick's Streng's model is that it allows us to treat sacrificial creeds positively, as viable paths by which people sought to ultimately transform themselves and their community. Of course, in terms of the severity of its demands, Aztec/Mesoamerican religion was a 'dark' faith, yet this may, in the end, be the best explanation for the system's persistence over such a wide area for so many thousands of years. Its appeal evidently came from its willingness to publicly tackle the inevitability of death; for unlike many creeds, Aztec religion never paid lip service to the idea of dying for God or seeking an afterlife.

Footnotes

1. Even the earliest Mesoamerican quasi-farming cultures at Durron and Coxcalton show evidence of sacrificial practices. See R. S. MacNesh and M. L. Fowler *et al*, *The Prehistory of Tehuacan Valley* Vol.5, (Austin, 1972) p.84 and Robert D. Dienna, 'Religion and Social Organisation in Formative Times,' in Kurt V. Flannery (ed.) *The Mesoamerican Village*, (New York, 1976), p.351.
2. Significantly, an early observer, Duran, found that the rite was Coahuitl, meaning 'Feast which belongs to one and all' Fray Duran, trans. F. Horcasitas and D. Heyden, *Book of the Gods, and Rites of the Ancient Calendar* (Norman, 1971) p.77.

backup source: http://www.psilosophy.info/resources/search-manchurian-candidate.pdf

Table of Contents:

Author's Note
Part I - Origins of mind-control research
1. World War II
2. Cold War on the Mind
3. The Professor and the "A" Treatment
Part II - Intelligence or "Witches potions"
4. LSD
5. Concerning the Case of Dr. Frank Olsen
6. Them Unwitting: The Safehouses
7. Mushrooms to Counterculture
Part III - Spells - electrodes and hypnosis
8. Brainwashing
9. Human Ecology
10. The Gittinger Assessment System
11. Hypnosis
Part IV - Conclusions
12. The Search for the Truth

Author's Note

This book has grown out of the 16,000 pages of documents that the CIA released to me under the Freedom of Information Act. Without these documents, the best investigative reporting in the world could not have produced a book, and the secrets of CIA mind-control work would have remained buried forever, as the men who knew them had always intended. From the documentary base, I was able to expand my knowledge through interviews and readings in the behavioral sciences. Nevertheless, the final result is not the whole story of the CIA's attack on the mind. Only a few insiders could have written that, and they choose to remain silent. I have done the best I can to make the book as accurate as possible, but I have been hampered by the refusal of most of the principal characters to be interviewed and by the CIA's destruction in 1973 of many of the key documents.

I want to extend special thanks to the congressional sponsors of the Freedom of Information Act. I would like to think that they had my kind of research in mind when they passed into law the idea that information about the government belongs to the people, not to the bureaucrats. I am also grateful to the CIA officials who made what must have been a rather unpleasant decision to release the documents and to those in the Agency who worked on the actual mechanics of release. From my point of view, the system has worked extremely well.

I must acknowledge that the system worked almost not at all during the first six months of my three-year Freedom of Information struggle. Then in late 1975, Joseph Petrillo and Timothy Sullivan, two skilled and energetic lawyers with the firm of Fried, Frank, Shriver, Harris and Kampelman, entered the case. I had the distinct impression that the government attorneys took me much more seriously when my requests for documents started arriving on stationery with all those prominent partners at the top. An author should not need lawyers to write a book, but I would have had great difficulty without mine. I greatly appreciate their assistance.

What an author does need is editors, a publisher, researchers, consultants, and friends, and I have been particularly blessed with good ones. My very dear friend Taylor Branch edited the book, and I continue to be impressed with his great skill in making my ideas and language coherent. Taylor has also served as my agent, and in this capacity, too, he has done me great service.

I had a wonderful research team, without which I never could have sifted through the masses of material and run down leads in so many places. I thank them all, and I want to acknowledge their contributions. Diane St. Clair was the mainstay of the group. She put together a system for filing and cross-indexing that worked beyond all expectations. (Special thanks to Newsday's Bob Greene, whose suggestions for organizing a large investigation came to us through the auspices of Investigative Reporters and Editors, Inc.) Not until a week before the book was finally finished did I fail to find a document which I needed; naturally, it was something I had misfiled myself. Diane also contributed greatly to the Cold War chapter. Richard Sokolow made similar contributions to the Mushroom and Safehouse chapters. His work was solid, and his energy boundless. Jay Peterzell delved deeply into Dr. Cameron's "depatterning" work in Montreal and stayed with it when others might have quit. Jay also did first-rate studies of brainwashing and sensory deprivation. Jim Mintz and Ken Cummins provided excellent assistance in the early research stage.

The Center for National Security Studies, under my good friend Robert Borosage, provided physical support and research aid, and I would like to express my appreciation. My thanks also to Morton Halperin who continued the support when he became director of the Center. I also appreciated the help of Penny Bevis, Hannah Delaney, Florence Oliver, Aldora Whitman, Nick Fiore, and Monica Andres.

My sister, Dr. Patricia Greenfield, did excellent work on the CIA's interface with academia and on the Personality Assessment System. I want to acknowledge her contribution to the book and express my thanks and love.

There has been a whole galaxy of people who have provided specialized help, and I would like to thank them all: Jeff Kohan, Eddie Becker, Sam Zuckerman, Matthew Messelson, Julian Robinson, Milton Kline, Marty Lee, M. J. Conklin, Alan Scheflin, Bonnie Goldstein, Paul Avery, Bill Mills, John Lilly, Humphrey Osmond, Julie Haggerty, Patrick Oster, Norman Kempster, Bill Richards, Paul Magnusson, Andy Sommer, Mark Cheshire, Sidney Cohen, Paul Altmeyer, Fred and Elsa Kleiner, Dr. John Cavanagh, and Senator James Abourezk and his staff.

I sent drafts of the first ten chapters to many of the people I interviewed (and several who refused to be interviewed). My aim was to have them correct any inaccuracies or point out material taken out of context. The comments of those who responded aided me considerably in preparing the final book. My thanks for their assistance to Albert Hofmann, Telford Taylor, Leo Alexander, Walter Langer, John Stockwell, William Hood, Samuel Thompson, Sidney Cohen, Milton Greenblatt, Gordon Wasson, James Moore, Laurence Hinkle, Charles Osgood, John Gittinger (for Chapter 10 only), and all the others who asked not to be identified.

Finally, I would like to express my appreciation to my publisher, Times Books, and especially to my editor John J. Simon. John, Tom Lipscomb, Roger Jellinek, Gyorgyi Voros, and John Gallagher all believed in this book from the beginning and provided outstanding support. Thanks also go to Judith H. McQuown, who copyedited the manuscript, and Rosalyn T. Badalamenti, Times Books' Production Editor, who oversaw the whole production process.

John Marks
Washington, D.C. October 26, 1978

Part I - Origins of mind-control research

1. World War II

On the outskirts of Basel, Switzerland, overlooking the Rhine, lies the worldwide headquarters of the Sandoz drug and chemical empire. There, on the afternoon of April 16, 1943, Dr. Albert Hofmann made an extraordinary discovery - by accident.

At 37, with close-cropped hair and rimless glasses, Hofmann headed the company's research program to develop marketable drugs out of natural products. He was hard at work in his laboratory that warm April day when a wave of dizziness suddenly overcame him. The strange sensation was not unpleasant, and Hofmann felt almost as though he were drunk.

But he became quite restless. His nerves seemed to run off in different directions. The inebriation was unlike anything he had ever known before. Leaving work early, Hofmann managed a wobbly bicycle-ride home. He lay down and closed his eyes, still unable to shake the dizziness. Now the light of day was disagreeably bright. With the external world shut out, his mind raced along. He experienced what he would later describe as "an uninterrupted stream of fantastic images of extraordinary plasticity and vividness.... accompanied by an intense, kaleidoscope-like play of colors."

These visions subsided after a few hours, and Hofmann, ever the inquiring scientist, set out to find what caused them. He presumed he had somehow ingested one of the drugs with which he had been working that day, and his prime suspect was d-lysergic acid diethylamide, or LSD, a substance that he himself had first produced in the same lab five years earlier. As part of his search for a circulation stimulant, Hofmann had been examining derivatives of ergot, a fungus that attacks rye.

Ergot had a mysterious, contradictory reputation. In China and some Arab countries, it was thought to have medicinal powers, but in Europe it was associated with the horrible malady from the Middle Ages called St. Anthony's Fire, which struck periodically like the plague. The disease turned fingers and toes into blackened stumps and led to madness and death.

Hofmann guessed that he had absorbed some ergot derivative through his skin, perhaps while changing the filter paper in a suction bottle. To test his theory, he spent three days making up a fresh batch of LSD. Cautiously he swallowed 250 micrograms (less than 1/100,000 of an ounce). Hofmann planned to take more gradually through the day to obtain a result, since no known drug had any effect on the human body in such infinitesimal amounts. He had no way of knowing that because of LSD's potency, he had already taken several times what would later be termed an ordinary dose. Unexpectedly, this first speck of LSD took hold after about 40 minutes, and Hofmann was off on the first self-induced "trip" of modern times.[1]

Hofmann recalls he felt "horrific... I was afraid. I feared I was becoming crazy. I had the idea I was out of my body. I thought I had died. I did not know how it would finish. If you know you will come back from this very strange world, only then can you enjoy it." Of course, Hofmann had no way of knowing that he would return. While he had quickly recovered from his accidental trip three days earlier, he did not know how much LSD had caused it or whether the present dose was more than his body could detoxify. His mind kept veering off into an unknown dimension, but he was unable to appreciate much beyond his own terror.

Less than 200 miles from Hofmann's laboratory, doctors connected to the S.S. and Gestapo were doing experiments that led to the testing of mescaline (a drug which has many of the mind-changing qualities of LSD) on prisoners at Dachau. Germany's secret policemen had the notion, completely alien to Hofmann, that they could use drugs like mescaline to bring unwilling people under their control. According to research team member Walter Neff, the goal of the Dachau experiments was "to eliminate the will of the person examined."

At Dachau, Nazis took the search for scientific knowledge of military value to its most awful extreme. There, in a closely guarded, fenced-off part of the camp, S.S. doctors studied such questions as the amount of time a downed airman could survive in the North Atlantic in February. Information of this sort was considered important to German security, since skilled pilots were in relatively short supply. So, at Heinrich Himmler's personal order, the doctors at Dachau simply sat by huge tubs of ice water with stopwatches and timed how long it took immersed prisoners to die. In other experiments, under the cover of "aviation medicine," inmates were crushed to death in high-altitude pressure chambers (to learn how high pilots could safely fly), and prisoners were shot, so that special blood coagulants could be tested on their wounds.

The mescaline tests at Dachau run by Dr. Kurt Plotner were not nearly so lethal as the others in the "aviation" series, but the drug could still cause grave damage, particularly to anyone who already had some degree of mental instability. The danger was increased by the fact that the mescaline was administered covertly by S.S. men who spiked the prisoners' drinks. Unlike Dr. Hofmann, the subjects had no idea that a drug was causing their extreme disorientation. Many must have feared they had gone stark mad all on their own. Always, the subjects of these experiments were Jews, gypsies, Russians, and other groups on whose lives the Nazis placed little or no value. In no way were any of them true volunteers, although some may have come forward under the delusion that they would receive better treatment.

After the war, Neff told American investigators that the subjects showed a wide variety of reactions. Some became furious; others were melancholy or gay, as if they were drunk. Not surprisingly, "sentiments of hatred and revenge were exposed in every case." Neff' noted that the drug caused certain people to reveal their "most intimate secrets." Still, the Germans were not ready to accept mescaline as a substitute for their more physical methods of interrogation. They went on to try hypnosis in combination with the drug, but they apparently never felt confident that they had found a way to assume command of their victim's mind.

Even as the S.S. doctors were carrying on their experiments at Dachau, the Office of Strategic Services (OSS), America's wartime intelligence agency, set up a "truth drug" committee under Dr. Winfred Overholser, head of St. Elizabeth's Hospital in Washington. The committee quickly tried and rejected mescaline, several barbiturates, and scopolamine. Then, during the spring of 1943, the committee decided that *Cannabis indica* - or marijuana - showed the most promise, and it started a testing program in cooperation with the Manhattan Project, the TOP SECRET effort to build an atomic bomb. It is not clear why OSS turned to the bomb makers for help, except that, as one former Project official puts it, "Our secret was so great, I guess we were safer than anyone else." Apparently, top Project leaders, who went to incredible lengths to preserve security, saw no danger in trying out drugs on their personnel.

The Manhattan Project supplied the first dozen test subjects, who were asked to swallow a concentrated, liquid form of marijuana that an American pharmaceutical company furnished in small glass vials. A Project man who was present recalls: "It didn't work the way we wanted. Apparently the human system would not take it all at once orally. The subjects would lean over and vomit." What is more, they disclosed no secrets, and one subject wound up in the hospital.

Back to the drawing board went the OSS experts. They decided that the best way to administer the marijuana was inhalation of its fumes. Attempts were made to pour the solution on burning charcoal, and an OSS officer named George White (who had already succeeded in knocking himself out with an overdose of the relatively potent substance) tried out the vapor, without sufficient effect, at St. Elizabeth's. Finally, the OSS group discovered a delivery system which had been known for years to jazz musicians and other users: the cigarette. OSS documents reported that smoking a mix of tobacco and the marijuana essence brought on a "state of irresponsibility, causing the subject to be loquacious and free in his impartation of information."

The first field test of these marijuana-laced cigarettes took place on May 27, 1943. The subject was one August Del Gracio, who was described in OSS documents as a "notorious New York gangster."[2] George White, an Army captain who had come to OSS from the Federal Bureau of Narcotics, administered the drug by inviting Del Gracio up to his apartment for a smoke and a chat. White had been talking to Del Gracio earlier about securing the Mafia's cooperation to keep Axis agents out of the New York waterfront and to prepare the way for the invasion of Sicily.[3]

Del Gracio had already made it clear to White that he personally had taken part in killing informers who had squealed to the Feds. The gangster was as tough as they came, and if he could be induced to talk under the influence of a truth drug, certainly German prisoners could - or so the reasoning went. White plied him with cigarettes until "subject became high and extremely garrulous." Over the next two hours, Del Gracio told the Federal agent about the ins and outs of the drug trade (revealing information so sensitive that the CIA deleted it from the OSS documents it released 34 years later). At one point in the conversation, after Del Gracio had begun to talk, the gangster told White, "Whatever you do, don't ever use any of the stuff I'm telling you." In a subsequent session, White packed the cigarettes with so much marijuana that Del Gracio became unconscious for about an hour. Yet, on the whole the experiment was considered a success in "loosening the subject's tongue."

While members of the truth-drug committee never believed that the concentrated marijuana could compel a person to confess his deepest secrets, they authorized White to push ahead with the testing. On the next stage, he and a Manhattan Project counterintelligence man borrowed 15 to 18 thick dossiers from the FBI and went off to try the marijuana on suspected Communist soldiers stationed in military camps outside Atlanta, Memphis, and New Orleans. According to White's Manhattan Project sidekick, a Harvard Law graduate and future judge, they worked out a standard interrogation technique:

Before we went in, George and I would buy cigarettes, remove them from the bottom of the pack, use a hypodermic needle to put in the fluid, and leave the cigarettes in a shot glass to dry. Then, we resealed the pack.... We sat down with a particular soldier and tried to win his confidence. We would say something like "This is better than being overseas and getting shot at," and we would try to break them. We started asking questions from their [FBI] folder, and we would let them see that we had the folder on them... We had a pitcher of ice water on the table, and we knew the drug had taken effect when they reached for a glass. The stuff actually worked.... Everyone but one - and he didn't smoke - gave us more information than we had before.

The Manhattan Project lawyer remembers this swing through the South with George White as a "good time." The two men ate in the best restaurants and took in all the sights. "George was quite a guy," he says. "At the Roosevelt Hotel in New Orleans after we had interviewed our men, we were lying on the beds when George took out his pistol and shot his initials into the molding that ran along the ceiling. He used his 22 automatic, equipped with a silencer, and he emptied several clips." Asked if he tried out the truth drug himself, the lawyer says, "Yes. The cigarettes gave you a feeling of walking a couple of feet off the floor. I had a pleasant sensation of well-being. ... The fellows from my office wouldn't take a cigarette from me for the rest of the war."

Since World War II, the United States government, led by the Central Intelligence Agency, has searched secretly for ways to control human behavior. This book is about that search, which had its origins in World War II. The CIA programs were not only an extension of the OSS quest for a truth drug, but they also echoed such events as the Nazi experiments at Dachau and Albert Hofmann's discovery of LSD.

By probing the inner reaches of consciousness, Hofmann's research took him to the very frontiers of knowledge. As never before in history, the warring powers sought ideas from scientists capable of reaching those frontiers - ideas that could make the difference between victory and defeat. While Hofmann himself remained aloof, in the Swiss tradition, other scientists, like Albert Einstein, helped turned the abstractions of the laboratory into incredibly destructive weapons. Jules Verne's notions of spaceships touching the moon stopped being absurd when Wernher von Braun's rockets started pounding London. With their creations, the scientists reached beyond the speculations of science fiction. Never before had their discoveries been so breathtaking and so frightening. Albert Hofmann's work touched upon the fantasies of the mind - accessible, in ancient legends, to witches and wizards who used spells and potions to bring people under their sway. In the early scientific age, the dream of controlling the brain took on a modern form in Mary Shelley's creation, Dr. Frankenstein's monster. The dream would be updated again during the Cold War era to become the Manchurian Candidate, the assassin whose mind was controlled by a hostile government.[4] Who could say for certain that such a fantasy would not be turned into a reality like Verne's rocket stories or Einstein's calculations? And who should be surprised to learn that government agencies - specifically the CIA - would swoop down on Albert Hofmann's lab in an effort to harness the power over the mind that LSD seemed to hold?

From the Dachau experiments came the cruelty that man was capable of heaping upon his fellows in the name of advancing science and helping his country gain advantage in war. To say that the Dachau experiments are object lessons of how far people can stretch ends to justify means is to belittle by cliché what occurred in the concentration camps. Nothing the CIA ever did in its postwar search for mind-control technology came close to the callous killing of the Nazi "aviation research." Nevertheless, in their attempts to find ways to manipulate people, Agency officials and their agents crossed many of the same ethical barriers. They experimented with dangerous and unknown techniques on people who had no idea what was happening. They systematically violated the free will and mental dignity of their subjects, and, like the Germans, they chose to victimize special groups of people whose existence they considered, out of prejudice and convenience, less worthy than their own. Wherever their extreme experiments went, the CIA sponsors picked for subjects their own equivalents of the Nazis' Jews and gypsies: mental patients, prostitutes, foreigners, drug addicts, and prisoners, often from minority ethnic groups.

In the postwar era, American officials straddled the ethical and the cutthroat approaches to scientific research. After an Allied tribunal had convicted the first echelon of surviving Nazi war criminals - the Görings and Speers - American prosecutors charged the Dachau doctors with "crimes against humanity" at a second Nuremberg trial. None of the German scientists expressed remorse. Most claimed that someone else had carried out the vilest experiments. All said that issues of moral and personal responsibility are moot in state-sponsored research. What is critical, testified Dr. Karl Brandt, Hitler's personal physician, is "whether the experiment is important or unimportant." Asked his attitude toward killing human beings in the course of medical research, Brandt replied, "Do you think that one can obtain any worthwhile fundamental results without a definite toll of lives?" The judges at Nuremberg rejected such defenses and put forth what came to be known as the Nuremberg Code on scientific research.[5] Its main points were simple: Researchers must obtain full voluntary consent from all subjects; experiments should yield fruitful results for the good of society that can be obtained in no other way; researchers should not conduct tests where death or serious injury might occur, "except, perhaps" when the supervising doctors also serve as subjects. The judges - all Americans - sentenced seven of the Germans, including Dr. Brandt, to death by hanging. Nine others received long prison sentences. Thus, the U.S. government put its full moral force behind the idea that there were limits on what scientists could do to human subjects, even when a country's security was thought to hang in the balance.

The Nuremberg Code has remained official American policy ever since 1946, but, even before the verdicts were in, special U.S. investigating teams were sifting through the experimental records at Dachau for information of military value. The report of one such team found that while part of the data was "inaccurate," some of the conclusions, if confirmed, would be "an important complement to existing knowledge." Military authorities sent the records, including a description of the mescaline and hypnosis experiments, back to the United States. None of the German mind-control research was ever made public.

Immediately after the war, large political currents began to shift in the world, as they always do. Allies became enemies and enemies became allies. Other changes were fresh and yet old. In the United States, the new Cold War against communism carried with it a piercing sense of fear and a sweeping sense of mission - at least as far as American leaders were concerned. Out of these feelings and out of that overriding American faith in advancing technology came the CIA's attempts to tame hostile minds and make spy fantasies real. Experiments went forward and the CIA's scientists - bitten, sometimes obsessed - kept going back to their laboratories for one last adjustment. Some theories were crushed, while others emerged in unexpected ways that would have a greater impact outside the CIA than in the world of covert operations. Only one aspect remained constant during the quarter-century of active research: The CIA's interest in controlling the human mind had to remain absolutely secret.

World War II provided more than the grand themes of the CIA's behavioral programs. It also became the formative life experience of the principal CIA officials, and, indeed, of the CIA itself as an institution. The secret derring-do of the OSS was new to the United States, and the ways of the OSS would grow into the ways of the CIA. OSS leaders would have their counterparts later in the Agency. CIA officials tended to have known the OSS men, to think like them, to copy their methods, and even, in some cases, to be the same people. When Agency officials wanted to launch their massive effort for mind control, for instance, they got out the old OSS documents and went about their goal in many of the same ways the OSS had. OSS leaders enlisted outside scientists; Agency officials also went to the most prestigious ones in academia and industry, soliciting aid for the good of the country. They even approached the same George White who had shot his initials in the hotel ceiling while on OSS assignment.

Years later, White's escapades with OSS and CIA would carry with them a humor clearly unintended at the time. To those directly involved, influencing human behavior was a deadly serious business, but qualities like bumbling and pure craziness shine through in hindsight. In the CIA's campaign, some of America's most distinguished behavioral scientists would stick all kinds of drugs and wires into their experimental subjects - often dismissing the obviously harmful effects with theories reminiscent of the learned nineteenth-century physicians who bled their patients with leeches and belittled the ignorance of anyone who questioned the technique. If the schemes of these scientists to control the mind had met with more success, they would be much less amusing. But so far, at least, the human spirit has apparently kept winning. That - if anything - is the saving grace of the mind-control campaign.

World War II signaled the end of American isolation and innocence, and the United States found it had a huge gap to close, with its enemies and allies alike, in applying underhanded tactics to war. Unlike Britain, which for hundreds of years had used covert operations to hold her empire together, the United States had no tradition of using subversion as a secret instrument of government policy. The Germans, the French, the Russians, and nearly everyone else had long been involved in this game, although no one seemed as good at it as the British.

Clandestine lobbying by British agents in the United States led directly to President Franklin Roosevelt's creation of the organization that became OSS in 1942. This was the first American agency set up to wage secret, unlimited war. Roosevelt placed it under the command of a Wall Street lawyer and World War I military hero, General William "Wild Bill" Donovan. A burly, vigorous Republican millionaire with great intellectual curiosity, Donovan started as White House intelligence adviser even before Pearl Harbor, and he had direct access to the President.

Learning at the feet of the British who made available their expertise, if not all their secrets, Donovan put together an organization where nothing had existed before. A Columbia College and Columbia Law graduate himself, he tended to turn to the gentlemanly preserves of the Eastern establishment for recruits. (The initials OSS were said to stand for "Oh So Social.") Friends - or friends of friends - could be trusted. "Old boys" were the stalwarts of the British secret service, and, as with most other aspects of OSS, the Americans followed suit.

One of Donovan's new recruits was Richard Helms, a young newspaper executive then best known for having gained an interview with Adolf Hitler in 1936 while working for United Press. Having gone to Le Rosey, the same Swiss prep school as the Shah of Iran, and then on to clubby Williams College Helms moved easily among the young OSS men. He was already more taciturn than the jovial Donovan, but he was equally ambitious and skilled as a judge of character. For Helms, OSS spywork began a lifelong career. He would become the most important sponsor of mind-control research within the CIA, nurturing and promoting it throughout his steady climb to the top position in the Agency.

Like every major wartime official from President Roosevelt down, General Donovan believed that World War II was in large measure a battle of science and organization. The idea was to mobilize science for defense, and the Roosevelt administration set up a costly, intertwining network of research programs to deal with everything from splitting the atom to preventing mental breakdowns in combat. Donovan named Boston industrialist Stanley Lovell to head OSS Research and Development and to be the secret agency's liaison with the government scientific community.

A Cornell graduate and a self-described "saucepan chemist," Lovell was a confident energetic man with a particular knack for coming up with offbeat ideas and selling them to others Like most of his generation, he was an outspoken patriot. He wrote in his diary shortly after Pearl Harbor: "As James Hilton said, 'Once at war, to reason is treason.' My job is clear - to do all that is in me to help America."

General Donovan minced no words in laying out what he expected of Lovell: "I need every subtle device and every underhanded trick to use against the Germans and Japanese - by our own people - but especially by the underground resistance programs in all the occupied countries. You'll have to invent them all, Lovell, because you're going to be my man." Thus Lovell recalled his marching orders from Donovan, which he instantly received on being introduced to the blustery, hyperactive OSS chief. Lovell had never met anyone with Donovan's personal magnetism.

Lovell quickly turned to some of the leading lights in the academic and private sectors. A special group - called Division 19 - within James Conant's National Defense Research Committee was set up to produce "miscellaneous weapons" for OSS and British intelligence. Lovell's strategy, he later wrote, was "to stimulate the Peck's Bad Boy beneath the surface of every American scientist and to say to him, 'Throw all your normal law-abiding concepts out the window. Here's a chance to raise merry hell.'"

Dr. George Kistiakowsky, the Harvard chemist who worked on explosives research during the war (and who became science adviser to Presidents Eisenhower and Kennedy) remembers Stanley Lovell well: "Stan came to us and asked us to develop ways for camouflaging explosives which could be smuggled into enemy countries." Kistiakowsky and an associate came up with a substance which was dubbed "Aunt Jemima" because it looked and tasted like pancake mix. Says Kistiakowsky: "You could bake bread or other things out of it. I personally took it to a high-level meeting at the War Department and ate cookies in front of all those characters to show them what a wonderful invention it was. All you had to do was attach a powerful detonator, and it exploded with the force of dynamite." Thus disguised, "Aunt Jemima" could be slipped into occupied lands. It was credited with blowing up at least one major bridge in China.

Lovell encouraged OSS behavioral scientists to find something that would offend Japanese cultural sensibilities. His staff anthropologists reported back that nothing was so shameful to the Japanese soldier as his bowel movements. Lovell then had the chemists work up a skatole compound which duplicated the odor of diarrhea. It was loaded into collapsible tubes, flown to China, and distributed to children in enemy-occupied cities. When a Japanese officer appeared on a crowded street, the kids were encouraged to slip up behind him and squirt the liquid on the seat of his pants. Lovell named the product "Who? Me?" and he credited it with costing the Japanese "face."

Unlike most weapons, "Who? Me?" was not designed to kill or maim. It was a "harassment substance" designed to lower the morale of individual Japanese. The inspiration came from academicians who tried to make a science of human behavior. During World War II, the behavioral sciences were still very much in their infancy, but OSS - well before most of the outside world - recognized their potential in warfare. Psychology and psychiatry, sociology, and anthropology all seemed to offer insights that could be exploited to manipulate the enemy.

General Donovan himself believed that the techniques of psychoanalysis might be turned on Adolf Hitler to get a better idea of "the things that made him tick," as Donovan put it. Donovan gave the job of being the Fuhrer's analyst to Walter Langer, a Cambridge, Massachusetts psychoanalyst whose older brother William had taken leave from a chair of history at Harvard to head OSS Research and Analysis.[6] Langer protested that a study of Hitler based on available data would be highly uncertain and that conventional psychiatric and psychoanalytic methods could not be used without direct access to the patient. Donovan was not the sort to be deterred by such details. He told Langer to go ahead anyway.

With the help of a small research staff, Langer looked through everything he could find on Hitler and interviewed a number of people who had know the German leader. Aware of the severe limitations on his information, but left no choice by General Donovan, Langer plowed ahead and wrote up a final study. It pegged Hitler as a "neurotic psychopath" and proceeded to pick apart the Führer's psyche. Langer, since retired to Florida, believes he came "pretty close" to describing the real Adolf Hitler. He is particularly proud of his predictions that the Nazi leader would become increasingly disturbed as Germany suffered more and more defeats and that he would commit suicide rather than face capture.

One reason for psychoanalyzing Hitler was to uncover vulnerabilities that could be covertly exploited. Stanley Lovell seized upon one of Langer's ideas - that Hitler might have feminine tendencies - and got permission from the OSS hierarchy to see if he could push the Führer over the gender line.[7] "The hope was that his moustache would fall off and his voice become soprano," Lovell wrote. Lovell used OSS's agent network to try to slip female sex hormones into Hitler's food, but nothing apparently came of it. Nor was there ever any payoff to other Lovell schemes to blind Hitler permanently with mustard gas or to use a drug to exacerbate his suspected epilepsy. The main problem in these operations - all of which were tried - was to get Hitler to take the medicine. Failure of the delivery schemes also kept Hitler alive - OSS was simultaneously trying to poison him.[8]

Without question, murdering a man was a decisive way to influence his behavior, and OSS scientists developed an arsenal of chemical and biological poisons that included the incredibly potent botulinus toxin, whose delivery system was a gelatin capsule smaller than the head of a pin. Lovell and his associates also realized there were less drastic ways to manipulate an enemy's behavior, and they came up with a line of products to cause sickness, itching, baldness, diarrhea, and/or the odor thereof. They had less success finding a drug to compel truthtelling, but it was not for lack of trying.

Chemical and biological substances had been used in wartime long before OSS came on the scene. Both sides had used poison gas in World War I; during the early part of World War II, the Japanese had dropped deadly germs on China and caused epidemics; and throughout the war, the Allies and Axis powers alike had built up chemical and biological warfare (CBW) stockpiles, whose main function turned out, in the end, to be deterring the other side. Military men tended to look on CBW as a way of destroying whole armies and even populations. Like the world's other secret services, OSS individualized CBW and made it into a way of selectively but secretly embarrassing, disorienting, incapacitating, injuring, or killing an enemy.

As diversified as were Lovell's scientific duties for OSS, they were narrow in comparison with those of his main counterpart in the CIA's postwar mind-control program, Dr. Sidney Gottlieb. Gottlieb would preside over investigations that ranged from advanced research in amnesia by electroshock to dragnet searches through the jungles of Latin America for toxic leaves and barks. Fully in the tradition of making Hitler moustacheless, Gottlieb's office would devise a scheme to make Fidel Castro's beard fall out; like Lovell, Gottlieb would personally provide operators with deadly poisons to assassinate foreign leaders like the Congo's Patrice Lumumba, and he would be equally at ease discussing possible applications of new research in neurology. On a much greater scale than Lovell's, Gottlieb would track down every conceivable gimmick that might give one person leverage over another's mind. Gottlieb would preside over arcane fields from handwriting analysis to stress creation, and he would rise through the Agency along with his bureaucratic patron, Richard Helms.

Early in the war, General Donovan got another idea from the British, whose psychologists and psychiatrists had devised a testing program to predict the performance of military officers. Donovan thought such a program might help OSS sort through the masses of recruits who were being rushed through training. To create an assessment system for Americans, Donovan called in Harvard psychology professor Henry "Harry" Murray. In 1938 Murray had written Explorations of Personality, a notable book which laid out a whole battery of tests that could be used to size up the personalities of individuals. "Spying is attractive to loonies," states Murray. "Psychopaths, who are people who spend their lives making up stories, revel in the field." The program's prime objective, according to Murray, was keeping out the crazies, as well as the "sloths, irritants, bad actors, and free talkers."

Always in a hurry, Donovan gave Murray and a distinguished group of colleagues only 15 days until the first candidates arrived to be assessed. In the interim, they took over a spacious estate outside Washington as their headquarters. In a series of hurried meetings, they put together an assessment system that combined German and British methods with Murray's earlier research. It tested a recruit's ability to stand up under pressure, to be a leader, to hold liquor, to lie skillfully, and to read a person's character by the nature of his clothing.

More than 30 years after the war, Murray remains modest in his claims for the assessment system, saying that it was only an aid in weeding out the "horrors" among OSS candidates. Nevertheless, the secret agency's leaders believed in its results, and Murray's system became a fixture in OSS, testing Americans and foreign agents alike. Some of Murray's young behavioral scientists, like John Gardner,[9] would go on to become prominent in public affairs, and, more importantly, the OSS assessment program would be recognized as a milestone in American psychology. It was the first systematic effort to evaluate an individual's personality in order to predict his future behavior. After the war, personality assessment would become a new field in itself, and some of Murray's assistants would go on to establish OSS-like systems at large corporations, starting with AT&T. They also would set up study programs at universities, beginning with the University of California at Berkeley.[10] As would happen repeatedly with the CIA's mind-control research, OSS was years ahead of public developments in behavioral theory and application.

In the postwar years, Murray would be superseded by a young Oklahoma psychologist John Gittinger, who would rise in the CIA on the strength of his ideas about how to make a hard science out of personality assessment and how to use it to manipulate people. Gittinger would build an office within CIA that refined both Murray's assessment function and Walter Langer's indirect analysis of foreign leaders. Gittinger's methods would become an integral part of everyday Agency operations, and he would become Sid Gottlieb's protégé.

Stanley Lovell reasoned that a good way to kill Hitler - and the OSS man was always looking for ideas - would be to hypnotically control a German prisoner to hate the Gestapo and the Nazi regime and then to give the subject a hypnotic suggestion to assassinate the Führer. The OSS candidate would be let loose in Germany where he would take the desired action, "being under a compulsion that might not be denied," as Lovell wrote.

Lovell sought advice on whether this scheme would work from New York psychiatrist Lawrence Kubie and from the famed Menninger brothers, Karl and William. The Menningers reported that the weight of the evidence showed hypnotism to be incapable of making people do anything that they would not otherwise do. Equally negative, Dr. Kubie added that if a German prisoner had a logical reason to kill Hitler or anyone else, he would not need hypnotism to motivate him.

Lovell and his coworkers apparently accepted this skeptical view of hypnosis, as did the overwhelming majority of psychologists and psychiatrists in the country. At the time, hypnosis was considered a fringe activity, and there was little recognition of either its validity or its usefulness for any purpose - l*et al*one covert operations. Yet there were a handful of serious experimenters in the field who believed in its military potential. The most vocal partisan of this view was the head of the Psychology Department at Colgate University, George "Esty" Estabrooks. Since the early 1930s, Estabrooks had periodically ventured out from his sleepy upstate campus to advise the military on applications of hypnotism.

Estabrooks acknowledged that hypnosis did not work on everyone and that only one person in five made a good enough subject to be placed in a deep trance, or state of somnambulism. He believed that only these subjects could be induced to such things against their apparent will as reveal secrets or commit crimes. He had watched respected members of the community make fools of themselves in the hands of stage hypnotists, and he had compelled his own students to reveal fraternity secrets and the details of private love affairs - all of which the subjects presumably did not want to do.

Still his experience was limited. Estabrooks realized that the only certain way to know whether a person would commit a crime like murder under hypnosis was to have the person kill someone. Unwilling to settle the issue on his own by trying the experiment, he felt that government sanction of the process would relieve the hypnotist of personal responsibility. "Any 'accidents' that might occur during the experiments will simply be charged to profit and loss," he wrote, "a very trifling portion of that enormous wastage in human life which is part and parcel of war."

After Pearl Harbor, Estabrooks offered his ideas to OSS, but they were not accepted by anyone in government willing to carry them to their logical conclusion. He was reduced to writing books about the potential use of hypnotism in warfare. Cassandra-like, he tried to warn America of the perils posed by hypnotic control. His 1945 novel, Death in the Mind, concerned a series of seemingly treasonable acts committed by Allied personnel: an American submarine captain torpedoes one of our own battleships, and the beautiful heroine starts acting in an irrational way which serves the enemy. After a perilous investigation, secret agent Johnny Evans learns that the Germans have been hypnotizing Allied personnel and conditioning them to obey Nazi commands. Evans and his cohorts, shaken by the many ways hypnotism can be used against them, set up elaborate countermeasures and then cannot resist going on the offensive. Objections are heard from the heroine, who by this time has been brutally and rather graphically tortured. She complains that "doing things to people's minds" is "a loathsome way to fight." Her qualms are brushed aside by Johnny Evans, her lover and boss. He sets off after the Germans - "to tamper with their minds; Make them traitors; Make them work for us."

In the aftermath of the war, as the U.S. national security apparatus was being constructed, the leaders of the Central Intelligence Agency would adopt Johnny Evans' mission - almost in those very words. Richard Helms, Sid Gottlieb, John Gittinger, George White, and many others would undertake a far-flung and complicated assault on the human mind. In hypnosis and many other fields, scientists even more eager than George Estabrooks would seek CIA approval for the kinds of experiments they would not dare perform on their own. Sometimes the Agency men concurred; on other occasions, they reserved such experiments for themselves. They would tamper with many minds and inevitably cause some to be damaged. In the end, they would minimize and hide their deeds, and they would live to see doubts raised about the health of their own minds.

Notes 1

The information on Albert Hofmann's first LSD trip and background on LSD came from an interview by the author with Hofmann, a paper by Hofmann called "The Discovery of LSD and Subsequent Investigations on Naturally Occurring Hallucinogens," another interview with Hofmann by Michael Horowitz printed in the June 1976 High Times magazine, and from a CIA document on LSD produced by the Office of Scientific Intelligence, August 30, 1955, titled "The Strategic Medical Significance of LSD-25."

Information on the German mescaline and hypnosis experiments at Dachau came from "Technical Report no. 331-45, German Aviation Research at the Dachau Concentration Camp," October, 1945, US Naval Technical Mission in Europe, found in the papers of Dr. Henry Beecher. Additional information came from Trials of War Criminals Before the Nuremberg Tribunal, the book Doctors of Infamy by Alexander Mitscherlich and Fred Mielke (New York: H. Schuman, 1949), interviews with prosecution team members Telford Taylor, Leo Alexander, and James McHaney, and an article by Dr. Leo Alexander, "Sociopsychologic Structure of the SS," Archives of Neurology and Psychiatry, May, 1948, Vol. 59, pp. 622-34.

The OSS experience in testing marijuana was described in interviews with several former Manhattan Project counterintelligence men, an OSS document dated June 21, 1943, Subject: Development of "truth drug," given the CIA identification number A/B, I, 12/1; from document A/B, I, 64/34, undated, Subject: Memorandum Relative to the use of truth drug in interrogation; document dated June 2, 1943, Subject: Memorandum on T. D. A "confidential memorandum," dated April 4, 1954, found in the papers of George White, also was helpful. The quote on US prisoners passing through Manchuria came from document 19, 18 June 1953, Subject: ARTICHOKE Conference.

The information on Stanley Lovell came from his book, Of Spies and Strategems (Englewood Cliffs, N.J.: Prentice-Hall, 1963), from interviews with his son Richard, a perusal of his remaining papers, interviews with George Kistiakowsky and several OSS veterans, and from "Science in World War II, the Office of Scientific Research and Development" in Chemistry: A History of the Chemistry Components of the National Defense Research Committee, edited by W. A. Noyes, Jr. (Boston: Little, Brown & Company, 1948).

Dr. Walter Langer provided information about his psychoanalytic portrait of Hitler, as did his book, The Mind of Adolf Hitler (New York: Basic Books, 1972). Dr. Henry Murray also gave an interview, as did several OSS men who had been through his assessment course. Murray's work is described at length in a book published after the war by the OSS Assessment staff, Assessment of Men (New York: Rinehart & Company, 1948).

Material on George Estabrooks came from his books, Hypnotism (New York: E. P. Dutton and Co., 1945) and Death in the Mind, co-authored with Richard Lockridge (New York: E. P. Dutton, 1945), and interviews with his daughter, Doreen Estabrooks Michl, former colleagues, and Dr. Milton Kline.

Footnotes 1

1. While Hofmann specifically used the word "trip" in a 1977 interview to describe his consciousness-altering experience, the word obviously had no such meaning in 1943 and is used here anachronistically.
2. Del Gracio's name was deleted by the CIA from the OSS document that described the incident, but his identity was learned from the papers of George White, whose widow donated them to Foothills College in Los Altos, California. CIA officials cut virtually all the names from the roughly 16,000 pages of its own papers and the few score pages from OSS that it released to me under the Freedom of Information Act. However, as in this case, many of the names could be found through collateral sources.
3. Naval intelligence officers eventually made a deal in which mob leaders promised to cooperate, and as a direct result, New York Governor Thomas Dewey ordered Del Gracio's chief, boss of bosses, Charles "Lucky" Luciano freed from jail in 1946.
4. The term "Manchurian *Candida*te" came into the language in 1959 when author Richard Condon made it the title of his best-selling novel that later became a popular movie starring Laurence Harvey and Frank Sinatra. The story was about a joint Soviet-Chinese plot to take an American soldier captured in Korea, condition him at a special brainwashing center located in Manchuria, and create a remote-controlled assassin who was supposed to kill the President of the United States. Condon consulted with a wide variety of experts while researching the book, and some inside sources may well have filled him in on the gist of a discussion that took place at a 1953 meeting at the CIA on behavior control. Said one participant, "... individuals who had come out of North Korea across the Soviet Union to freedom recently apparently had a blank period of disorientation while passing through a special zone in Manchuria." The CIA and military men at this session promised to seek more information, but the matter never came up again in either the documents released by the Agency or in the interviews done for

this book.

5. The Code was suggested in essentially its final form by prosecution team consultant, Dr. Leo Alexander, a Boston psychiatrist.
6. Four months before Pearl Harbor, Donovan had enlisted Walter Langer to put together a nationwide network of analysts to study the morale of the country's young men, who, it was widely feared, were not enthusiastic about fighting a foreign war. Pearl Harbor seemed to solve this morale problem, but Langer stayed with Donovan as a part-time psychoanalytic consultant.
7. Langer wrote that Hitler was "masochistic in the extreme inasmuch as he derives sexual pleasure from punishment inflicted on his own body. There is every reason to suppose that during his early years, instead of identifying himself with his father as most boys do, he identified with his mother. This was perhaps easier for him than for most boys since, as we have seen, there is a large feminine component in his physical makeup.... His extreme sentimentality, his emotionality, his occasional softness, and his weeping, even after he became Chancellor, may be regarded as manifestations of a fundamental pattern that undoubtedly had its origin in his relationship to his mother."
8. Although historians have long known that OSS men had been in touch with the German officers who tried to assassinate Hitler in 1944, the fact that OSS independently was trying to murder him has eluded scholars of the period. Stanley Lovell gave away the secret in his 1963 book, Of Spies and Strategems, but he used such casual and obscure words that the researchers apparently did not notice. Lovell wrote: "I supplied now and then a carbamate or other quietus medication, all to be injected into der Führer's carrots, beets, or whatever." A "quietus medicine" is a generic term for a lethal poison, of which carbamates are one type.
9. Gardner, a psychologist teaching at Mount Holyoke College, helped Murray set up the original program and went on to open the West Coast OSS assessment site at a converted beach club in San Juan Capistrano. After the war, he would become Secretary of HEW in the Johnson administration and founder of Common Cause.
10. Murray is not at all enthusiastic with the spinoffs. "Some of the things done with it turn your stomach," he declares.

2. Cold War on the Mind

CIA officials started preliminary work on drugs and hypnosis shortly after the Agency's creation in 1947, but the behavior-control program did not really get going until the Hungarian government put Josef Cardinal Mindszenty on trial in 1949. With a glazed look in his eyes, Mindszenty confessed to crimes of treason he apparently did not commit. His performance recalled the Moscow purge trials of 1937 and 1938 at which tough and dedicated party apparatchiks had meekly pleaded guilty to long series of improbable offenses. These and a string of postwar trials in other Eastern European countries seemed staged, eerie, and unreal. CIA men felt they had to know how the Communists had rendered the defendants zombielike. In the Mindszenty case, a CIA Security Memorandum declared that "some unknown force" had controlled the Cardinal, and the memo speculated that the communist authorities had used hypnosis on him.

In the summer of 1949, the Agency's head of Scientific Intelligence made a special trip to Western Europe to find out more about what the Soviets were doing and "to apply special methods of interrogation for the purpose of evaluation of Russian practices." In other words, fearful that the communists might have used drugs and hypnosis on prisoners, a senior CIA official used exactly the same techniques on refugees and returned prisoners from Eastern Europe. On returning to the United States, this official recommended two courses of action: first, that the Agency consider setting up an escape operation to free Mindszenty; and second, that the CIA train and send to Europe a team skilled in "special" interrogation methods of the type he had tried out in Europe.

By the spring of 1950, several other CIA branches were contemplating the operational use of hypnosis. The Office of Security, whose main job was to protect Agency personnel and facilities from enemy penetration, moved to centralize all activity in this and other behavioral fields. The Security chief, Sheffield Edwards, a former Army colonel who a decade later would personally handle joint CIA-Mafia operations, took the initiative by calling a meeting of all interested Agency parties and proposing that interrogation teams be formed under Security's command. Security would use the teams to check out agents and defectors for the whole CIA. Each team would consist of a psychiatrist, a polygraph (lie detector) expert trained in hypnosis, and a technician. Edwards agreed not to use the teams operationally without the permission of a high-level committee. He called the project BLUEBIRD, a code name which, like all Agency names, had no significance except perhaps to the person who chose it. Edwards classified the program TOP SECRET and stressed the extraordinary need for secrecy. On April 20, 1950, CIA Director Roscoe Hillenkoetter approved BLUEBIRD and authorized the use of unvouchered funds to pay for its most sensitive areas. The CIA's behavior-control program now had a bureaucratic structure.

The chief of Scientific Intelligence attended the original BLUEBIRD meeting in Sheffield Edwards' office and assured those present that his office would keep trying to gather all possible data on foreign - particularly Russian - efforts in the behavioral field. Not long afterward, his representative arranged to inspect the Nuremberg Tribunal records to see if they contained anything useful to BLUEBIRD. According to a CIA psychologist who looked over the German research, the Agency did not find much of specific help. "It was a real horror story, but we learned what human beings were capable of," he recalls. "There were some experiments on pain, but they were so mixed up with sadism as not to be useful.... How the victim coped was very interesting."

At the beginning, at least, there was cooperation between the scientists and the interrogators in the CIA. Researchers from Security (who had no special expertise but who were experienced in police work) and researchers from Scientific Intelligence (who lacked operational background but who had academic training) pored jointly over all the open literature and secret reports. They quickly realized that the only way to build an effective defense against mind control was to understand its offensive possibilities. The line between offense and defense - if it ever existed - soon became so blurred as to be meaningless. Nearly every Agency document stressed goals like "controlling an individual to the point where he will do our bidding against his will and even against such fundamental laws of nature as self-preservation." On reading one such memo, an Agency officer wrote to his boss: "If this is supposed to be covered up as a defensive feasibility study, it's pretty damn transparent."

Three months after the Director approved BLUEBIRD, the first team traveled to Japan to try out behavioral techniques on human subjects - probably suspected double agents. The three men arrived in Tokyo in July 1950, about a month after the start of the Korean War. No one needed to impress upon them the importance of their mission. The Security Office ordered them to conceal their true purpose from even the U.S. military authorities with whom they worked in Japan, using the cover that they would be performing "intensive polygraph" work. In stifling, debilitating heat and humidity, they tried out combinations of the depressant sodium amytal with the stimulant benzedrine on each of four subjects, the last two of whom also received a second stimulant, picrotoxin. They also tried to induce amnesia. The team considered the tests successful, but the CIA documents available on the trip give only the sketchiest outline of what happened.[1] Then around October 1950, the BLUEBIRD team used "advanced" techniques on 25 subjects, apparently North Korean prisoners of war.

By the end of that year, a Security operator, Morse Allen, had become the head of the BLUEBIRD program. Forty years old at the time, Allen had spent most of his earlier career rooting out the domestic communist threat, starting in the late 1930s when he had joined the Civil Service Commision and set up its first security files on communists. ("He knows their methods," wrote a CIA colleague.) During World War II, Allen had served with Naval intelligence, first pursuing leftists in New York and then landing with the Marines on Okinawa. After the war, he went to the State Department, only to leave in the late 1940s because he felt the Department was whitewashing certain communist cases. He soon joined the CIA's Office of Security. A suspicious man by inclination and training, Allen took nothing at face value. Like all counterintelligence or security operators, his job was to show why things are not what they seem to be. He was always thinking ahead and behind, punching holes in surface realities. Allen had no academic training for behavioral research (although he did take a short course in hypnotism, a subject that fascinated him). He saw the BLUEBIRD job as one that called for studying every last method the communists might use against the United States and figuring out ways to counter them.

The CIA had schooled Morse Allen in one field which in the CIA's early days became an important part of covert operations: the use of the polygraph. Probably more than any intelligence service in the world, the Agency developed the habit of strapping its foreign agents - and eventually, its own employees - into the "box." The polygraph measures physiological changes that might show lying - heartbeat, blood pressure, perspiration, and the like. It has never been foolproof. In 1949 the Office of Security estimated that it worked successfully on seven out of eight cases, a very high fraction but not one high enough for those in search of certainty. A psychopathic liar, a hypnotized person, or a specially trained professional can "beat" the machine. Moreover, the skill of the person running the polygraph and asking the questions determines how well the device will work. "A good operator can make brilliant use of the polygraph without plugging it in," claims one veteran CIA case officer. Others maintain only somewhat less extravagantly that its chief value is to deter agents tempted to switch loyalties or reveal secrets. The power of the machine - real and imagined - to detect infidelity and dishonesty can be an intimidating factor.[2] Nevertheless, the polygraph cannot compel truth. Like Pinocchio's nose, it only indicates lying. In addition, the machine requires enough physical control over the subject to strap him in. For years, the CIA tried to overcome this limitation by developing a "super" polygraph that could be aimed from afar or concealed in a chair. In this field, as in many others, no behavior control scheme was too farfetched to investigate, and Agency scientists did make some progress.

In December 1950, Morse Allen told his boss, Paul Gaynor, a retired brigadier general with a long background in counterintelligence and interrogation, that he had heard of experiments with an "electro-sleep" machine in a Richmond, Virginia hospital. Such an invention appealed to Allen because it supposedly put people to sleep without shock or convulsions. The BLUEBIRD team had been using drugs to bring on a state similar to a hypnotic trance, and Allen hoped this machine would allow an operator to put people into deep sleep without having to resort to chemicals. In theory, all an operator had to do was to attach the electrode-tipped wires to the subject's head and let the machine do the rest. It cost about $250 and was about twice the size of a table-model dictating machine. "Although it would not be feasible to use it on any of our own people because there is at least a theoretical danger of temporary brain damage," Morse Allen wrote, "it would possibly be of value in certain areas in connection with POW interrogation or on individuals of interest to this Agency." The machine never worked well enough to get into the testing stage for the CIA.

At the end of 1951, Allen talked to a famed psychiatrist (whose name, like most of the others, the CIA has deleted from the documents released) about a gruesome but more practical technique. This psychiatrist, a cleared Agency consultant, reported that electroshock treatments could produce amnesia for varying lengths of time and that he had been able to obtain information from patients as they came out of the stupor that followed shock treatments. He also reported that a lower setting of the Reiter electroshock machine produced an "excruciating pain" that, while nontherapeutic, could be effective as "a third degree method" to make someone talk. Morse Allen asked if the psychiatrist had ever taken advantage of the "groggy" period that followed normal electroshock to gain hypnotic control of his patients. No, replied the psychiatrist, but he would try it in the near future and report back to the Agency. The psychiatrist also mentioned that continued electroshock treatments could gradually reduce a subject to the "vegetable level," and that these treatments could not be detected unless the subject was given EEG tests within two weeks. At the end of a memo laying out this information, Allen noted that portable, battery-driven electroshock machines had come on the market.

Shortly after this Morse Allen report, the Office of Scientific Intelligence recommended that this same psychiatrist be given $100,000 in research funds "to develop electric shock and hypnotic techniques." While Allen thought this subject worth pursuing, he had some qualms about the ultimate application of the shock treatments: "The objections would, of course, apply to the use of electroshock if the end result was creation of a 'vegetable.' [I] believe that these techniques should not be considered except in gravest emergencies, and neutralization by confinement and/or removal from the area would be far more appropriate and certainly safer."

In 1952 the Office of Scientific Intelligence proposed giving another private doctor $100,000 to develop BLUEBIRD-related "neurosurgical techniques" - presumably lobotomy-connected.[3] Similarly, the Security office planned to use outside consultants to find out about such techniques as ultrasonics, vibrations, concussions, high and low pressure, the uses of various gases in airtight chambers, diet variations, caffeine, fatigue, radiation, heat and cold, and changing light. Agency officials looked into all these areas and many others. Some they studied intensively; others they merely discussed with consultants.

The BLUEBIRD mind-control program began when Stalin was still alive, when the memory of Hitler was fresh, and the terrifying prospect of global nuclear war was just sinking into popular consciousness. The Soviet Union had subjugated most of Eastern Europe, and a Communist party had taken control over the world's most populous nation, China. War had broken out in Korea, and Senator Joseph McCarthy's anti-Communist crusade was on the rise in the United States. In both foreign and domestic politics, the prevailing mood was one of fear even paranoia.

American officials have pointed to the Cold War atmosphere ever since as an excuse for crimes and excesses committed then and afterward. One recurring litany in national security investigations has been the testimony of the exposed official citing Cold War hysteria to justify an act that he or she would not otherwise defend. The apprehensions of the Cold War do not provide a moral or legal shield for such acts, but they do help explain them. Even when the apprehensions were not well founded, they were no less real to the people involved.

It was also a time when the United States had achieved a new preeminence in the world. After World War II, American officials wielded the kind of power that diplomats frequently dream of. They established new alliances, new rulers, and even new nations to suit their purposes. They dispensed guns, favors, and aid to scores of nations. Consequently, American officials were noticed, respected, and pampered wherever they went - as never before. Their new sense of importance and their Cold War fears often made a dangerous combination - it is a fact of human nature that anyone who is both puffed up and afraid is someone to watch out for.

In 1947 the National Security Act created not only the CIA but also the National Security Council - in sum, the command structure for the Cold War. Wartime OSS leaders like William Donovan and Allen Dulles lobbied feverishly for the Act. Officials within the new command structure soon put their fear and their grandiose notions to work. Reacting to the perceived threat, they adopted a ruthless and warlike posture toward anyone they considered an enemy - most especially the Soviet Union. They took it upon themselves to fight communism and things that might lead to communism everywhere in the world. Few citizens disagreed with them; they appeared to express the sentiments of most Americans in that era, but national security officials still preferred to act in secrecy. A secret study commission under former President Hoover captured the spirit of their call to clandestine warfare:

> It is now clear we are facing an implacable enemy whose avowed objective is world domination by whatever means and at whatever cost. There are no rules in such a game. Hitherto acceptable long-standing American concepts of "fair play" must be reconsidered. We must develop effective espionage and counterespionage services and must learn to subvert, sabotage, and destroy our enemies by more clever, more sophisticated, and more effective methods than those used against us.

The men in the new CIA took this job quite seriously. "We felt we were the first line of defense in the anti-Communist crusade," recalls Harry Rositzke, an early head of the Agency's Soviet Division. "There was a clear and heady sense of mission - a sense of what a huge job this was." Michael Burke, who was chief of CIA covert operations in Germany before going on to head the New York Yankees and Madison Square Garden, agrees: "It was riveting.... One was totally absorbed in something that has become misunderstood now, but the Cold War in those days was a very real thing with hundreds of thousands of Soviet troops, tanks, and planes poised on the East German border, capable of moving to the English Channel in forty-eight hours." Hugh Cunningham, an Agency official who stayed on for many years, remembers that survival itself was at stake, "What you were made to feel was that the country was in desperate peril and we had to do whatever it took to save it."

BLUEBIRD and the CIA's later mind-control programs sprang from such alarm. As a matter of course, the CIA was also required to learn the methods and intentions of all possible foes. "If the CIA had not tried to find out what the Russians were doing with mind-altering drugs in the early 1950s, I think the then-Director should have been fired," says Ray Cline, a former Deputy Director of the Agency.

High Agency officials felt they had to know what the Russians were up to. Nevertheless, a careful reading of the contemporaneous CIA documents almost three decades later indicates that if the Russians were scoring breakthroughs in the behavior-control field - whose author they almost certainly were not - the CIA lacked intelligence to prove that. For example, a 1952 Security document, which admittedly had an ax to grind with the Office of Scientific Intelligence, called the data gathered on the Soviet programs "extremely poor." The author noted that the Agency's information was based on "second- or third-hand rumors, unsupported statements and non-factual data."[4] Apparently, the fears and fantasies aroused by the Mindszenty trial and the subsequent Korean War "brainwashing" furor outstripped the facts on hand. The prevalent CIA notion of a "mind-control gap" was as much of a myth as the later bomber and missile "gaps." In any case, beyond the defensive curiosity, mind control took on a momentum of its own.

As unique and frightening as the Cold War was, it did not cause people working for the government to react much differently to each other or power than at other times in American history. Bureaucratic squabbling went on right through the most chilling years of the behavior-control program. No matter how alarmed CIA officials became over the Russian peril, they still managed to quarrel with their internal rivals over control of Agency funds and manpower. Between 1950 and 1952, responsibility for mind control went from the Office of Security to the Scientific Intelligence unit back to Security again. In the process, BLUEBIRD was rechristened ARTICHOKE. The bureaucratic wars were drawn-out affairs, baffling to outsiders; yet many of the crucial turns in behavioral research came out of essentially bureaucratic considerations on the part of the contending officials. In general, the Office of Security was full of pragmatists who were anxious to weed out communists (and homosexuals) everywhere. They believed the intellectuals from Scientific Intelligence had failed to produce "one new, usable paper, suggestion, drug, instrument, name of an individual, etc., etc.," as one document puts it. The learned gentlemen from Scientific Intelligence felt that the former cops, military men, and investigators in Security lacked the technical background to handle so awesome a task as controlling the human mind.

"Jurisdictional conflict was constant in this area," a Senate committee would state in 1976. A 1952 report to the chief of the CIA's Medical Staff (itself a participant in the infighting) drew a harsher conclusion: "There exists a glaring lack of cooperation among the various intra-Agency groups fostered by petty jealousies and personality differences that result in the retardation of the enhancing and advancing of the Agency as a body." When Security took ARTICHOKE back from Scientific Intelligence in 1952, the victory lasted only two and one-half years before most of the behavioral work went to yet another CIA outfit, full of Ph.D.s with operational experience - the Technical Services Staff (TSS).[5]

There was bureaucratic warfare outside the CIA as well, although there were early gestures toward interagency cooperation. In April 1951 the CIA Director approved liaison with Army, Navy, and Air Force intelligence to avoid duplication of effort. The Army and Navy were both looking for truth drugs, while the prime concern of the Air Force was interrogation techniques used on downed pilots. Representatives of each service attended regular meetings to discuss ARTICHOKE matters. The Agency also invited the FBI, but J. Edgar Hoover's men stayed away.

During their brief period of cooperation, the military and the CIA also exchanged information with the British and Canadian governments. At the first session in June 1951, the British representative announced at the outset that there had been nothing new in the interrogation business since the days of the Inquisition and that there was little hope of achieving valuable results through research. He wanted to concentrate on propaganda and political warfare as they applied to such threats as communist penetration of trade unions. The CIA's minutes of the session record that this skeptical Englishman finally agreed to the importance of behavioral research, but one doubts the sincerity of this conversion. The minutes also record a consensus of "no conclusive evidence" that either Western countries or the Soviets had made any "revolutionary progress" in the field, and describe Soviet methods as "remarkably similar ... to the age-old methods." Nonetheless, the representatives of the three countries agreed to continue investigating behavior-control methods because of their importance to "cold war operations." To what extent the British and Canadians continued cannot be told. The CIA did not stop until the 1970s.

Bureaucratic conflict was not the only aspect of ordinary government life that persisted through the Cold War. Officials also maintained their normal awareness of the ethical and legal consequences of their decisions. Often they went through contorted rationalizations and took steps to protect themselves, but at least they recognized and paused over the various ethical lines before crossing them. It would be unfair to say that all moral awareness evaporated. Officials agonized over the consequences of their acts, and much of the bureaucratic record of behavior control is the history of officials dealing with moral conflicts as they arose.

The Security office barely managed to recruit the team psychiatrist in time for the first mission to Japan, and for years, Agency officials had trouble attracting qualified medical men to the project. Speculating why, one Agency memo listed such reasons as the CIA's comparatively low salaries for doctors and ARTICHOKE's narrow professional scope, adding that a candidate's "ethics might be such that he might not care to cooperate in certain more revolutionary phases of our project." This consideration became explicit in Agency recruiting. During the talent search, another CIA memo stated why another doctor seemed suitable: "His ethics are such that he would be completely cooperative in any phase of our program, regardless of how revolutionary it may be."

The matter was even more troublesome in the task of obtaining guinea pigs for mind-control experiments. "Our biggest current problem," noted one CIA memo, "is to find suitable subjects." The men from ARTICHOKE found their most convenient source among the flotsam and jetsam of the international spy trade: "individuals of dubious loyalty, suspected agents or plants, subjects having known reason for deception, etc." as one Agency document described them. ARTICHOKE officials looked on these people as "unique research material," from whom meaningful secrets might be extracted while the experiments went on.

It is fair to say that the CIA operators tended to put less value on the lives of these subjects than they did on those of American college students, upon whom preliminary, more benign testing was done. They tailored the subjects to suit the ethical sensitivity of the experiment. A psychiatrist who worked on an ARTICHOKE team stresses that no one from the Agency wanted subjects to be hurt. Yet he and his colleagues were willing to treat dubious defectors and agents in a way which not only would be professionally unethical in the United States but also an indictable crime. In short, these subjects were, if not expendable, at least not particularly prized as human beings. As a CIA psychologist who worked for a decade in the behavior-control program, puts it, "One did not put a high premium on the civil rights of a person who was treasonable to his own country or who was operating effectively to destroy us." Another ex-Agency psychologist observes that CIA operators did not have "a universal concept of mankind" and thus were willing to do things to foreigners that they would have been reluctant to try on Americans. "It was strictly a patriotic vision," he says.

ARTICHOKE officials never seemed to be able to find enough subjects. The professional operators - particularly the traditionalists - were reluctant to turn over agents to the Security men with their unproved methods. The field men did not particularly want outsiders, such as the ARTICHOKE crew, getting mixed up in their operations. In the spy business, agents are very valuable property indeed, and operators tend to be very protective of them. Thus the ARTICHOKE teams were given mostly the dregs of the clandestine underworld to work on.

Inexorably, the ARTICHOKE men crossed the clear ethical lines. Morse Allen believed it proved little or nothing to experiment on volunteers who gave their informed consent. For all their efforts to act naturally, volunteers still knew they were playing in a make-believe game. Consciously or intuitively, they understood that no one would allow them to be harmed. Allen felt that only by testing subjects "for whom much is at stake (perhaps life and death)," as he wrote, could he get reliable results relevant to operations. In documents and conversation, Allen and his coworkers called such realistic tests "terminal experiments" - terminal in the sense that the experiment would be carried through to completion. It would not end when the subject felt like going home or when he or his best interest was about to be harmed. Indeed, the subject usually had no idea that he had ever been part of an experiment.

In every field of behavior control, academic researchers took the work only so far. From Morse Allen's perspective, somebody then had to do the terminal experiment to find out how well the technique worked in the real world: how drugs affected unwitting subjects, how massive electroshock influenced memory, how prolonged sensory deprivation disturbed the mind. By definition, terminal experiments went beyond conventional ethical and legal limits. The ultimate terminal experiments caused death, but ARTICHOKE sources state that those were forbidden.

For career CIA officials, exceeding these limits in the name of national security became part of the job, although individual operators usually had personal lines they would not cross. Most academics wanted no part of the game at this stage - nor did Agency men always like having these outsiders around. If academic and medical consultants were brought along for the terminal phase, they usually did the work overseas, in secret. As Cornell Medical School's famed neurologist Harold Wolff explained in a research proposal he made to the CIA, when any of the tests involved doing harm to the subjects, "We expect the Agency to make available suitable subjects and a proper place for the performance of the necessary experiments." Any professional caught trying the kinds of things the Agency came to sponsor - holding subjects prisoner, shooting them full of unwanted drugs - probably would have been arrested for kidnapping or aggravated assault. Certainly such a researcher would have been disgraced among his peers. Yet, by performing the same experiment under the CIA's banner, he had no worry from the law. His colleagues could not censure him because they had no idea what he was doing. And he could take pride in helping his country.

Without having been there in person, no one can know exactly what it felt like to take part in a terminal experiment. In any case, the subjects probably do not have fond memories of the experience. While the researchers sometimes resembled Alphonse and Gastone, they took themselves and their work very seriously. Now they are either dead, or, for their own reasons, they do not want to talk about the tests. Only in the following case have I been able to piece together anything approaching a firsthand account of a terminal experiment, and this one is quite mild compared to the others the ARTICHOKE men planned.

Notes 2

The origins of the CIA's ARTICHOKE program and accounts of the early testing came from the following Agency Documents # 192, 15 January 1953; #3,17 May 1949; A/B, I,8/1,24 February 1949; February 10, 1951 memo on Special Interrogations (no document #); A/B, II, 30/2, 28 September 1949; #5, 15 August 1949; #8, 27 September 1949; #6, 23 August 1949; #13, 5 April 1950; #18, 9 May 1950; #142 (transmittal slip), 19 May 1952; #124, 25 January 1952; A/B, IV, 23/32, 3 March 1952; #23, 21 June 1950; #10, 27 February 1950; #37, 27 October 1950; A/B, I, 39/1, 12 December 1950; A/B, II, 2/2, 5 March 1952; A/B, II, 2/1, 15 February 1952; A/B, V, 134/3, 3 December 1951; A/B, I, 38/5, 1 June 1951; and #400, undated, "Specific Cases of Overseas Testing and Applications of Behavioral Drugs."

The documents were supplemented by interviews with Ray Cline, Harry Rositzke, Michael Burke, Hugh Cunningham, and several other ex-CIA men who asked to remain anonymous. The Final Report of the Select Committee to Study Governmental Operations with Respect to Intelligence (henceforth called the Church Committee Report) provided useful background.

Documents giving background on terminal experiments include #A/B, II, 10/57; #A/B, II, 10/58, 31 August, 1954; #A/B, II, 10/ 17, 27 September 1954; and #A/B, I, 76/4, 21 March 1955.

Footnotes 2

1. For a better-documented case of narcotherapy and narcohypnosis, see Chapter 3.
2. While the regular polygraphing of CIA career employees apparently never has turned up a penetration agent in the ranks, it almost certainly has a deterrent effect on those considering coming out of the homosexual closet or on those considering dipping into the large sums of cash dispensed from proverbial black bags.
3. Whether the Agency ultimately funded this or the electric-shock proposal cited above cannot be determined from the documents.
4. The CIA refused to supply either a briefing or additional material when I asked for more background on Soviet behavior-control programs.
5. This Agency component, responsible for providing the supporting gadgets disguises, forgeries, secret writing, and weapons, has been called during its history the Technical Services Division and the Office of Technical Services as well as TSS, the name which will be used throughout this book.

3. The Professor and the "A" Treatment

The three men were all part of the same Navy team, traveling together to Germany. Their trip was so sensitive that they had been ordered to ignore each other, even as they waited in the terminal at Andrews Air Force Base outside Washington on a sweltering August morning in 1952. Just the month before, Gary Cooper had opened in High Noon, and the notion of showdown - whether with outlaws or communists - was in the air. With war still raging in Korea, security consciousness was high. Even so, the secrecy surrounding this Navy mission went well beyond ordinary TOP SECRET restrictions, for the team was slated to link up in Frankfurt with a contingent from the most hush-hush agency of all, the CIA. Then the combined group was going to perform dangerous experiments on human subjects. Both Navy and CIA officials believed that any disclosure about these tests would cause grave harm to the American national interest.

The Navy team sweated out a two-hour delay at Andrews before the four-engine military transport finally took off. Not until the plane touched down at the American field in the Azores did one of the group, a representative of Naval intelligence, flash a prearranged signal indicating that they were not being watched and they could talk. "It was all this cloak-and-dagger crap," recalls another participant, Dr. Samuel Thompson, a psychiatrist, physiologist, and pharmacologist who was also a Navy commander.

The third man in the party was G. Richard Wendt, chairman of the Psychology Department at the University of Rochester and a part-time Navy contractor. A small 46-yearold man with graying blond hair and a fair-sized paunch, Wendt had been the only one with companionship during the hours of decreed silence. He had brought along his attractive young assistant, ostensibly to help him with the experiments. She was not well received by the Navy men, nor would she be appreciated by the CIA operators in Frankfurt. The behavior-control field was very much a man's world, except when women subjects were used. The professor's relationship with this particular lady was destined to become a source of friction with his fellow experimenters, and, eventually, a topic of official CIA reporting.

In theory, Professor Wendt worked under Dr. Thompson's supervision in a highly classified Navy program called Project CHATTER, but the strong-minded psychologist did not take anyone's orders easily. Very much an independent spirit, Wendt ironically, had accepted CHATTER's goal of weakening, if not eliminating, free will in others. The Navy program, which had started in 1947, was aimed at developing a truth drug that would force people to reveal their innermost secrets.

Thompson, who inherited Wendt and CHATTER in 1951 when he became head of psychiatric research at the Naval Medical Research Institute, remembers Naval intelligence telling him of the need for a truth drug in case "someone planted an Abomb in one of our cities and we had twelve hours to find out from a person where it was. What could we do to make him talk?" Thompson concedes he was always "negative" about the possibility that such a drug could ever exist, but he cites the fear that the Russians might develop their own miracle potion as reason enough to justify the program. Also, Thompson and the other U.S. officials could not resist looking for a pill or panacea that would somehow make their side all-knowing or all-powerful.

Professor Wendt had experimented with drugs for the Navy before he became involved in the search for a truth serum. His earlier work had been on the use of Dramamine and other methods to prevent motion sickness, and now that he was doing more sensitive research, the Navy hid it under the cover of continuing his "motion sickness" study. At the end of 1950, the Navy gave Wendt a $300,000 contract to study such substances as barbiturates, amphetamines, alcohol, and heroin. To preserve secrecy, which often reached fetish proportions in mind-control research, the money flowed to him not through Navy channels but out of the Secretary of Defense's contingency fund. For those drugs that were not available from pharmaceutical companies, Navy officials went to the Federal Bureau of Narcotics. The Commissioner of Narcotics personally signed the papers, and special couriers carried pouches of illegal drugs through Washington streets and then up to the professor at Rochester. Receipts show that the Bureau sent the Navy 30 grams of pure heroin and 11 pounds of "Mexican grown" marijuana, among other drugs.

Like most serious drug researchers, Wendt sampled everything first before testing on assistants and students. The drug that took up the most space in his first progress report was heroin. He had became his own prime subject. At weekly intervals, he told the Navy, the psychologist gave himself heroin injections and then wrote down his reactions as he moved through the "full range" of his life: driving, shopping, recreation, manual work, family relations, and sexual activity. He noted in himself "slight euphoria ... heightened aesthetic appreciation ... absentminded behavior ... lack of desire to operate at full speed ... lack of desire for alcohol ... possibly reduced sex interest ... feeling of physical well-being." He concluded in his report that heroin could have "some, but slight value for interrogation" if used on someone "worked on for a long period of time."[1]

Wendt never had any trouble getting student volunteers. He simply posted a notice on a campus bulletin board, and he wound up with a long waiting list. He chose only men subjects over 21, and he paid everyone accepted after a long interview $1.00 an hour. With so much government money to spend, he hired over 20 staff assistants, and he built a whole new testing facility in the attic of the school library. Wendt was cautious with his students, and he apparently did not share the hard drugs with them. He usually tested subjects in small groups - four to eight at a time. He and his associates watched through a two-way mirror and wrote down the subjects' reactions. He always used both placebos (inert substances) and drugs; the students never knew what - if anything - they were taking. According to Dr. Thompson, to have alerted them in advance and thus given themselves a chance to steel themselves up "would have spoiled the experiment."

Nonetheless, Wendt's procedure was a far cry from true unwitting testing. Any drug that was powerful enough to break through an enemy's resistance could have a traumatic effect on the person taking it - particularly if the subject was totally unaware of what was happening. The Navy research plan was to do preliminary studies on subjects like Wendt's students, and then, as soon as the drug showed promise, to try it under field conditions. Under normal scientific research, the operational tests would not have been run before the basic work was finished. But the Navy could not wait. The drugs were to be tested on involuntary subjects. Thompson readily admits that this procedure was "unethical," but he says, "We felt we had to do it for the good of country."

During the summer of 1952, Professor Wendt announced that he had found a concoction "so special" that it would be "the answer" to the truth-drug problem, as Thompson recalls it. "I thought it would be a good idea to call the Agency," says Thompson. "I thought they might have someone with something to spill." Wendt was adamant on one point: He would not tell anyone in the Navy or the CIA what his potion contained. He would only demonstrate. Neither the CHATTER nor ARTICHOKE teams could resist the bait. The Navy had no source of subjects for terminal experiments, but the CIA men agreed to furnish the human beings - in Germany - even though they had no idea what Wendt had in store for his guinea pigs. The CIA named the operation CASTIGATE.

After settling into a Frankfurt hotel, Wendt, Thompson, and the Naval Intelligence man set out to meet the ARTICHOKE crew at the local CIA headquarters. It was located in the huge, elongated building that had housed the I. G. Farben industrial complex until the end of the war. The frantic bustle of a U.S. military installation provided ideal cover for this CIA base, and the arrival of a few new Americans attracted no special attention. The Navy group passed quickly through the lobby and rode up the elevator. At the CIA outer office, the team members had to show identification, and Thompson says they were frisked. The Naval Intelligence man had to check his revolver.

A secretary ushered the Navy group in to meet the ARTICHOKE contingent, which had arrived earlier from Washington. The party included team leader Morse Allen, his boss in the Office of Security, Paul Gaynor, and a prominent Washington psychiatrist who regularly left his private practice to fly off on special missions for the Agency. Also present were case officers from the CIA's Frankfurt base who had taken care of the support arrangements - the most important of which was supplying the subjects.

Everyone at the meeting wanted to know what drugs Wendt was going to use on the five selected subjects, who included one known double agent, one suspected double, and the three defectors. The professor still was not talking. Dr. Thompson asked what would happen if something went wrong and the subject died. He recalls one of the Frankfurt CIA men replying, "Disposal of the body would be no problem."

After the session ended, Thompson took Wendt aside and pointed out that since the professor, unlike Thompson, was neither a psychiatrist nor a pharmacologist, he was acting irresponsibly in not having a qualified physician standing by with antidotes in case of trouble. Wendt finally relented and confided in Thompson that he was going to slip the subjects a combination of the depressant Seconal, the stimulant Dexedrine, and tetrahydrocannabinol, the active ingredient in marijuana. Thompson was dumbfounded. He remembers wanting to shoot Wendt on the spot. These were all well-known drugs that had been thoroughly tested. Indeed, even the idea of mixing Seconal and Dexedrine was not original: The combined drug already had its own brand name - Dexamyl (and it would eventually have a street name, "the goofball"). Thompson quickly passed on to the CIA men what Wendt had in mind.[2] They, too, were more than a little disappointed.

Nevertheless, there was never any thought of stopping the experiments. The ARTICHOKE team had its own methods to try, even if Wendt's proved a failure, and the whole affair had developed its own momentum. Since this was one of the early ARTICHOKE trips into the field, the team was still working to perfect the logistics of testing. It had reserved two CIA "safehouses" in the countryside not far from Frankfurt, and Americans had been assigned to guard the experimental sites. Agency managers had already completed the paperwork for the installation of hidden microphones and two-way mirrors, so all the team members could monitor the interrogations.

The first safehouse proved to be a solid old farmhouse set picturesquely in the middle of green fields, far from the nearest dwelling. The ARTICHOKE and CHATTER groups drove up just as the CIA's carpenters were cleaning up the mess they had made in ripping a hole through the building's thick walls. The house had existed for several hundred years without an observation glass peering in on the sitting room, and it had put up some structural resistance to the workmen.

Subject #1 arrived in the early afternoon, delivered in a CIA sedan by armed operators, who had handcuffed him, shackled his feet, and made him lie down on the floor of the back seat. Agency officials described him as a suspected Russian agent, about 40 years old, who had a "Don Juan complex." One can only imagine how the subject must have reacted to these rather inconsistent Americans who only a few hours earlier had literally grabbed him out of confinement, harshly bound him, and sat more or less on top of him as they wandered through idyllic German farm country, and who now were telling him to relax as they engaged him in friendly conversation and offered him a beer. He had no way of knowing that it would be the last unspiked drink he would have for quite some time.

On the following morning, the testing started in earnest. Wendt put 20 mg. of Seconal in the subject's breakfast and then followed up with 50 mg. of Dexedrine in each of his two morning cups of coffee. Wendt gave him a second dose of Seconal in his luncheon beer. The subject was obviously not his normal self - whatever that was. What was clear was that Wendt was in way over his head, and even the little professor seemed to realize it. "I don't know how to deal with these people," he told the CIA psychiatric consultant. Wendt flatly refused to examine the subject, leaving the interrogation to the consultant. For his part, the consultant had little success in extracting information not already known to the CIA.

The third day was more of the same: Seconal with breakfast, Dexedrine and marijuana in a glass of water afterwards. The only break from the previous day's routine came at 10:10 A.M. when the subject was allowed to play a short poker game. Then he was given more of Wendt's drugs in two red capsules that were, he was told, "a prescription for his nerves." By 2:40 P.M., Wendt declared that this subject was not the right personality type for his treatment. He explained to his disgusted colleagues that if someone is determined to lie, these drugs will only make him a better liar. He said that the marijuana extract produced a feeling of not wanting to hold anything back and that it worked best on people who wanted to tell the truth but were afraid to. OSS had discovered the same thing almost a decade earlier.

Wendt retired temporarily from the scene, and the others concluded it would be a shame to waste a good subject. They decided to give him the "A" (for ARTICHOKE) treatment. This, too, was not very original. It had been used during the war to interrogate prisoners and treat shell-shocked soldiers. As practiced on the suspected Russian agent, it consisted of injecting enough sodium pentothal into the vein of his arm to knock him out and then, twenty minutes later, stimulating him back to semiconsciousness with a shot of Benzedrine. In this case, the benzedrine did not revive the subject enough to suit the psychiatric consultant and he told Dr. Thompson to give the subject another 10 mg. ten minutes later. This put the subject into a state somewhere between waking and sleeping - almost comatose and yet bug-eyed. In hypnotic tones that had to be translated into Russian by an interpreter, the consultant used the technique of "regression" to convince the subject he was talking to his wife Eva at some earlier time in his life. This was no easy trick, since a male interpreter was playing Eva. Nevertheless, the consultant states he could "create any fantasy" with 60 to 70 percent of his patients, using narcotherapy (as in this case) or hypnosis. For roughly an hour, the subject seemed to have no idea he was not speaking with his wife but with CIA operatives trying to find out about his relationship with Soviet intelligence. When the subject started to doze, the consultant had Thompson give him a doubled jolt of Benzedrine. A half hour later, the subject began to weep violently. The consultant decided to end the session, and in his most soothing voice, he urged the subject to fall asleep. As the subject calmed down, the consultant suggested, with friendly and soothing words, that the subject would remember nothing of the experience when he woke up.

Inducing amnesia was an important Agency goal. "From the ARTICHOKE point of view," states a 1952 document, "the greater the amnesia produced, the more effective the results." Obviously if a victim remembered the "A" treatment, it would stop being a closely guarded ARTICHOKE secret. Presumably, some subject who really did work for the Russians would tell them how the Americans had worked him over. This reality made "disposal" of ARTICHOKE subjects a particular problem. Killing them seems to have been ruled out, but Agency officials made sure that some stayed in foreign prisons for long periods of time. While in numerous specific cases, ARTICHOKE team members claimed success in making their subjects forget, their outside consultants had told them "that short of cutting a subject's throat, a true amnesia cannot be guaranteed." As early as 1950, the Agency had put out a contract to a private researcher to find a memory-destroying drug, but to no apparent avail.[3] In any case, it would be unreasonable to assume that over the years at least one ARTICHOKE subject did not shake off the amnesic commands and tell the Russians what happened to him. As was so often the case with CIA operations, the enemy probably had a much better idea of the Agency's activities than the folks back home.

Back at the safehouse, Wendt was far from through. Four more subjects would be brought to him. The next one was an alleged double agent whom the CIA had codenamed EXPLOSIVE. Agency documents describe him as a Russian "professional agent type" and "a hard-boiled individual who apparently has the ability to lie consistently but not very effectively." He was no stranger to ARTICHOKE team members who, a few months before, had plied him with a mixture of drugs and hypnosis under the cover of a "psychiatric-medical" exam. At that time, a professional hypnotist had accompanied the team, and he had given his commands through an elaborate intercom system to an interpreter who, in turn, was apparently able to put EXPLOSIVE under.[4] Afterward, the team reported to the CIA's Director that EXPLOSIVE had revealed "extremely valuable" information and that he had been made to forget his interrogation through a hypnotically induced amnesia. Since that time EXPLOSIVE had been kept in custody. Now he was being brought out to give Professor Wendt a crack at him with the Seconal-Dexedrine-marijuana combination.

This time, Wendt gave the subject all three drugs together in one beer, delivered at the cocktail hour. Next came Seconal in a dinner beer and then all three once more in a postprandial beer. There were little, if any, positive results. Wendt ended the session after midnight and commented, "At least we learned one thing from this experiment. The people you have to deal with here are different from American college students."

During the next week, the CIA men brought Wendt three more subjects, with little success. The general attitude toward Wendt became, in Thompson's words, "hostile as all hell." Both the Agency and the Navy groups questioned his competence. With one subject, the professor declared he had given too strong a dose; with the next, too weak. While he had advertised his drugs as tasteless, the subjects realized they had swallowed something. As one subject in the next room was being interrogated in Russian that no one was bothering to translate, Wendt took to playing the same pattern on the piano over and over for a half hour. While the final subject was being questioned, Wendt and his female assistant got a little tipsy on beer. Wendt became so distracted during this experiment that he finally admitted, "My thoughts are elsewhere." His assistant began to giggle. Her presence had become like an open sore - which was made more painful when Mrs. Wendt showed up in Frankfurt and the professor threatened to jump off a church tower, Thompson recalls.

Wendt is not alive to give his version of what happened, but both CIA and Navy sources are consistent in their description of him. ARTICHOKE team leader Morse Allen felt he had been the victim of "a fraud or at least a gross misinterpretation," and he described the trip as "a waste of time and money." A man who usually hid his feelings, Allen became livid when Wendt's assistant measured drugs out with a penknife. He recommended in his final report that those who develop drugs not be allowed to participate in future field testing. "This, of course, does not mean that experimental work is condemned by the ARTICHOKE team," he wrote, "but a common sense approach in this direction will preclude arguments, alibis, and complaints as in the recent situation." In keeping with this "common sense approach," he also recommended that as "an absolute rule," no women be allowed on ARTICHOKE missions - because of the possible danger and because "personal convenience, toilet facilities, etc., are complicated by the presence of women."

Morse Allen and his ARTICHOKE mates returned to the States still convinced that they could find ways to control human behavior, but the Navy men were shaken. Their primary contractor had turned out to be a tremendous embarrassment. Dr. Thompson stated he could never work with Wendt again. Navy officials soon summoned Wendt to Bethesda and told him they were canceling their support for his research. Adding insult to injury, they told him they expected refund of all unspent money. While the Navy managers made some effort to continue CHATTER at other institutions, the program never recovered from the Wendt fiasco. By the end of the next year, 1953, the Korean War had ended and the Navy abandoned CHATTER altogether.

Over the next two decades, the Navy would still sponsor large amounts of specialized behavioral research, and the Army would invest huge sums in schemes to incapacitate whole armies with powerful drugs. But the CIA clearly pulled far into the lead in mind control. In those areas in which military research continued, the Agency stayed way ahead. The CIA consistently was out on what was called the "cutting edge" of the research, sponsoring the lion's share of the most harrowing experiments. ARTICHOKE and its successor CIA programs became an enormous effort that harnessed the energies of hundreds of scientists.

The experience of the CIA psychiatric consultant provides a small personal glimpse of how it felt to be a soldier in the mind-control campaign. This psychiatrist, who insists on anonymity, estimates that he made between 125 and 150 trips overseas on Agency operations from 1952 through his retirement in 1966. "To be a psychiatrist chasing off to Europe instead of just seeing the same patients year after year, that was extraordinary," he reminisces. "I wish I was back in those days. I never got tired of it." He says his assignments called for "practicing psychiatry in an ideal way, which meant you didn't become involved with your patients. You weren't supposed to." Asked how he felt about using drugs on unwitting foreigners, he snaps, "Depends which side you were on. I never hurt anyone... . We were at war."

For the most part, the psychiatrist stopped giving the "A" treatment after the mid- 1950s but he continued to use his professional skills to assess and manipulate agents and defectors. His job was to help find out if a subject was under another country's control and to recommend how the person could be switched to the CIA's. In this work, he was contributing to the mainstream of CIA activity that permeates its institutional existence from its operations to its internal politics to its social life: the notion of controlling people. Finding reliable ways to do that is a primary CIA goal, and the business is often a brutal one. As former CIA Director Richard Helms stated in Senate testimony, "The clandestine operator ... is trained to believe you can't count on the honesty of your agent to do exactly what you want or to report accurately unless you own him body and soul."

Like all the world's secret services, the CIA sought to find the best methods of owning people and making sure they stayed owned. How could an operator be sure of an agent's loyalties? Refugees and defectors were flooding Western Europe, and the CIA wanted to exploit them. Which ones were telling the truth? Who was a deception agent or a provocateur. The Anglo-American secret invasion of Albania had failed miserably. Had they been betrayed?[5] Whom could the CIA trust?

One way to try to answer these questions is to use physical duress - or torture. Aside from its ethical drawbacks, however, physical brutality simply does not work very well. As a senior counterintelligence official explains, "If you have a blowtorch up someone's ass, he'll give you tactical information." Yet he will not be willing or able to play the modern espionage game on the level desired by the CIA. One Agency document excludes the use of torture "because such inhuman treatment is not only out of keeping with the traditions of this country, but of dubious effectiveness as compared with various supplemental psychoanalytical techniques."

The second and most popular method to get answers is traditional spy tradecraft. Given enough time, a good interrogator can very often find out a person's secrets. He applies persuasion and mental seduction, mixed with psychological pressures of every description - emotional carrots and sticks. A successful covert operator uses the same sorts of techniques in recruiting agents and making sure they stay in line. While the rest of the population may dabble in this sort of manipulation, the professional operator does it for a living, and he operates mostly outside the system of restraints that normally govern personal relationships. "I never gave a thought to legality or morality," states a retired and quite cynical Agency case officer with over 20 years' experience. "Frankly, I did what worked."

The operator pursues people he can turn into "controlled sources" - agents willing to do his bidding either in supplying intelligence or taking covert action. He seeks people in a position to do something useful for the Agency - or who someday might be in such a position, perhaps with CIA aid. Once he picks his target, he usually looks for a weakness or vulnerability he can play on. Like a good fisherman, the clever operator knows that the way to hook his prey is to choose an appropriate bait, which the target will think he is seizing because he wants to. The hook has to be firmly implanted; the agent sometimes tries to escape once he understands the implications of betraying his country. While the case officer might try to convince him he is acting for the good of his homeland, the agent must still face up to being branded a traitor.

Does every man have his price? Not exactly, states the senior counterintelligence man, but he believes a shrewd operator can usually find a way to reach anyone, particularly through his family. In developing countries, the Agency has caused family members to be arrested and mistreated by the local police, given or withheld medical care for a sick child, and, more prosaically, provided scholarships for a relative to study abroad. This kind of tactic does not work as well on a Russian or Western European, who does not live in a society where the CIA can exert pressure so easily.

Like a doctor's bedside manner or a lawyer's courtroom style, spy tradecraft is highly personalized. Different case officers swear by different approaches, and successful methods are carefully observed and copied. Most CIA operators seem to prefer using an ideological lure if they can. John Stockwell, who left the Agency in 1977 to write a book about CIA operations in Angola, believes his best agents were "people convinced they were doing the right thing ... who disliked communists and felt the CIA was the right organization." Stockwell recalls his Agency instructors "hammering away at the positive aspect of recruitment. This was where they established the myth of CIA case officers being good guys. They said we didn't use negative control, and we always made the relationship so that both parties were better off for having worked together." More cynical operators, like the one quoted above, take a different view: "You can't create real motivation in a person by waving the flag or by saying this is for the future good of democracy. You've got to have a firmer hold than that.... His opinions can change." This ex-operator favors approaches based either on revenge or helping the agent advance his career:

> Those are good motives because they can be created with the individual.... Maybe you start with a Communist party cell member and you help him become a district committee member by eliminating his competition, or you help him get a position where he can get even with someone. At the same time, he's giving you more and more information as he moves forward, and if you ever surface his reports, he's out of business. You've really got him wrapped up. You don't even have to tell him. He realizes it himself.

No matter what the approach to the prospective agent, the case officer tries to make money a factor in the relationship. Sometimes the whole recruiting pitch revolves around enrichment. In other instances, the case officer allows the target the illusion that he has sold out for higher motives. Always, however, the operator tries to use money to make the agent dependent. The situation can become sticky with money-minded agents when the case officer insists that part or all of the payments be placed in escrow, to prevent attracting undue attention. But even cash does not create control in the spy business. As the cynical case officer puts it, "Money is tenuous because somebody can always offer more."

Surprisingly, each of the CIA operators sampled agrees that overt blackmail is a highly overrated form of control. The senior counterintelligence man notes that while the Russians frequently use some variety of entrapment - sexual or otherwise - the CIA rarely did. "Very few [Agency] case officers were tough enough" to pull it off and sustain it, he says. "Anytime an agent has been forced to cooperate, you can take it for granted that he has two things on his mind: he is looking for a way out and for revenge. Given the slightest opportunity, he will hit you right between the eyes." Blackmail could backfire in unexpected ways. John Stockwell remembers an agent in Southeast Asia who wanted to quit: "The case officer leaned on the guy and said, 'Look, friend, we still need your intelligence, and we have receipts you signed which we can turn over to the local police.' The agent blew his brains out, leaving a suicide note regretting his cooperation with the CIA and telling how the Agency had tried to blackmail him. It caused some problems with the local government."

The case officer always tries to weave an ever-tightening web of control around his agent. His methods of doing so are so personal and so basic that they often reveal more about the case officer himself than the agent, reflecting his outlook and his personal philosophy. The cynical operator describes his usual technique, which turns out to be a form of false idealism: "You've got to treat a man as an equal and convince him you're partners in this thing. Even if he's a communist party member, you can't deal with him like a crumb. You sit down with him and ask how are the kids, and you remember that he told you last time that his son was having trouble in school. You build personal rapport. If you treat him like dirt or an object of use, eventually he'll turn on you or drop off the bandwagon."

John Stockwell's approach relies on the power of imagination in a humdrum world: "I always felt the real key was that you were offering something special - a real secret life - something that he and you only knew made him different from all the pedestrian paper shufflers in a government office or a boring party cell meeting. Everybody has a little of Walter Mitty in him - what a relief to know you really do work for the CIA in your spare time."

Sometimes a case officer wants to get the agent to do something he does not think he wants to do. One former CIA operator uses a highly charged metaphor to describe how he did it: "Sometimes one partner in a relationship wants to get into deviations from standard sex. If you have some control, you might be able to force your partner to try different things, but it's much better to lead her down the road a step at a time, to discuss it and fantasize until eventually she's saying, 'Let's try this thing.' If her inhibitions and moral reservations are eroded and she is turned on, it's much more fun and there's less chance of blowback [exposure, in spy talk].... It's the same with an agent."

All case officers - and particularly counterintelligence men - harbor recurring fears that their agents will betray them. The suspicious professional looks for telltale signs like lateness, nervousness, or inconsistency. He relies on his intuition. "The more you've been around agents, the more likely you are to sense that something isn't what it should be," comments the senior counterintelligence man. "It's like with children."

No matter how skillfully practiced, traditional spycraft provides only incomplete answers to the nagging question of how much the Agency can really trust an agent. All the sixth sense, digging, and deductive reasoning in the world do not produce certainty in a field that is based on deception and lies. Whereas the British, who invented the game, have historically understood the need for patience and a stiff upper lip, Americans tend to look for quick answers, often by using the latest technology. "We were very gimmick-prone," says the senior counterintelligence official. Gimmicks - machines, drugs, technical tricks - comprise the third method of behavior control, after torture and tradecraft. Like safecrackers who swear by the skill in their fingertips, most of the Agency's mainstream operators disparage newfangled gadgets. Many now claim that drugs, hypnosis, and other exotic methods actually detract from good tradecraft because they make operators careless and lazy.

Nevertheless, the operators and their high-level sponsors, like Allen Dulles and Richard Helms, consistently pushed for the magic technique - the deus ex machina - that would solve their problems. Caught in the muck and frustration of ordinary spywork, operators hoped for a miracle tool. Faced with liars and deceivers, they longed for a truth drug. Surrounded by people who knew too much, they sought a way to create amnesia. They dreamed of finding means to make unwilling people carry out specific tasks, such as stealing documents, provoking a fight, killing someone, or otherwise committing an antisocial act. Secret agents recruited by more traditional appeals to idealism, greed, ambition, or fear had always done such deeds, but they usually gave their spymasters headaches in the process. Sometimes they balked. Moreover, first they had to agree to serve the CIA. The best tradecraft in the world seldom works against a well-motivated target. (The cynical operator recalls offering the head of Cuban intelligence $1,000,00~in 1966 at a Madrid hotel - only to receive a flat rejection.) Plagued by the unsureness, Agency officials hoped to take the randomness - indeed, the free will - out of agent handling. As one psychologist who worked on behavior control describes it, "The problem of every intelligence operation is how do you remove the human element? The operators would come to us and ask for the human element to be removed." Thus the impetus toward mind-control research came not only from the lure of science and the fantasies of science fiction, it also came from the heart of the spy business.

Notes 3

The primary sources for the material on Professor Wendt's trip to Frankfurt were Dr. Samuel V. Thompson then of the Navy, the CIA psychiatric consultant, several of Wendt's former associates, as well as three CIA documents that described the testing: Document # 168, 19 September 1952, Subject: "Project LGQ"; Document # 168, 18 September 1952, Subject: Field Trip of ARTICHOKE team,20 August-September 1952; and #A/B, II, 33/21, undated, Subject: Special Comments.

Information on the Navy's Project CHATTER came from the Church Committee Report, Book I, pp. 337-38. Declassified Navy Documents N-23, February 13, 1951, Subject: Procurement of Certain Drugs; N-27, undated, Subject: Project CHATTER; N-29, undated, Subject: Status Report: Studies of Motion Sickness, Vestibular Function, and Effects of Drugs; N-35, October 27, 1951, Interim Report; N-38, 30 September, 1952, Memorandum for File; and N-39, 28 October, 1952, Memorandum for File.

The information on the heroin found in Wendt's safe comes from the Rochester Democrat and Chronicle, October 2, 1977 and considerable background on Wendt's Rochester testing program was found in the Rochester Times-Union, January 28, 1955. The CIA quote on heroin came from May 15,1952 OSI Memorandum to the Deputy Director, CIA, Subject: Special Interrogation.

Information on the Agency's interest in amnesia came from 14 January 1952 memo, Subject: BLUEBIRD/ARTICHOKE, Proposed Research; 7 March 1951, Subject: Informal Discussion with Chief [deleted] Regarding "Disposal"; 1 May 1951, Subject: Recommendation for Disposal of Maximum Custody Defectors; and #A/B, I, 75/13, undated, Subject: Amnesia.

The quote from Homer on nepenthe was found in Sidney Cohen's The Beyond Within: The LSD Story (New York: Atheneum, 1972).

The section on control came from interviews with John Stockwell and several other former CIA men.

Footnotes 3

1. What Wendt appears to have been getting at - namely, that repeated shots of heroin might have an effect on interrogation - was stated explicitly in a 1952 CIA document which declared the drug "can be useful in reverse because of the stresses produced when ... withdrawn from those addicted." Wendt's interest in heroin seems to have lasted to his death in 1977, long after his experiments had stopped. The woman who cleaned out his safe at that time told the Rochester Democrat and Chronicle she found a quantity of the white powder, along with syringes and a good many other drugs.
2. Being good undercover operators, the CIA men never let on to Wendt that they knew his secret, and Wendt was not about to give it away. Toward the end of the trip, he told the consultant he would feel "unpatriotic" if he were to share his secret because the ARTICHOKE team was "not competent" to use the drugs.
3. Homer reported the ancient Greeks had such a substance - nepenthe - "a drug to lull all pain and anger, and bring forgetfulness of every sorrow."
4. Neither Morse Allen nor anyone else on the ARTICHOKE teams spoke any foreign languages. Allen believed that the difficulty in communicating with the guinea pigs hampered ARTICHOKE research.
5. The answer was yes, in the sense that Soviet agent Harold "Kim" Philby, working as British intelligence's liaison with the CIA apparently informed his spymasters of specific plans to set up anticommunist resistance movements in Albania and all over Eastern Europe. The Russians almost certainly learned about CIA plans to overthrow communist rule in Eastern Europe and in the Soviet Union itself. Knowing of such operations presumably increased Soviet hostility.

Part II - Intelligence or "Witches potions"

4. LSD

Albert Hofmann's discovery of LSD in 1943 may have begun a new age in the exploration of the human mind, but it took six years for word to reach America. Even after Hofmann and his coworkers in Switzerland published their work in a 1947 article, no one in the United States seemed to notice. Then in 1949, a famous Viennese doctor named Otto Kauders traveled to the United States in search of research funds. He gave a conference at Boston Psychopathic Hospital,[1] a pioneering mental-health institution affiliated with Harvard Medical School, and he spoke about a new experimental drug called d-lysergic acid diethylamide. Milton Greenblatt, the hospital's research director, vividly recalls Kauders' description of how an infinitesimally small dose had rendered Dr. Hofmann temporarily "crazy." "We were very interested in anything that could make someone schizophrenic," says Greenblatt. If the drug really did induce psychosis for a short time, the Boston doctors reasoned, an antidote - which they hoped to find - might cure schizophrenia. It would take many years of research to show that LSD did not, in fact, produce a "model psychosis," but to the Boston doctors in 1949, the drug showed incredible promise. Max Rinkel, a neuropsychiatrist and refugee from Hitler's Germany, was so intrigued by Kauders' presentation that he quickly contacted Sandoz, the huge Swiss pharmaceutical firm where Albert Hofmann worked. Sandoz officials arranged to ship some LSD across the Atlantic.

The first American trip followed. The subject was Robert Hyde, a Vermont-born psychiatrist who was Boston Psychopathic's number-two man. A bold, innovative sort, Hyde took it for granted that there would be no testing program until he tried the drug. With Rinkel and the hospital's senior physician, H. Jackson DeShon looking on, Hyde drank a glass of water with 100 micrograms of LSD in it - less than half Hofmann's dose, but still a hefty jolt. DeShon describes Hyde's reaction as "nothing very startling." The perpetually active Hyde insisted on making his normal hospital rounds while his colleagues tagged along. Rinkel later told a scientific conference that Hyde became "quite paranoiac, saying that we had not given him anything. He also berated us and said the company had cheated us, given us plain water. That was not Dr. Hyde's normal behavior; he is a very pleasant man." Hyde's first experience was hardly as dramatic as Albert Hofmann's, but then the Boston psychiatrist had not, like Hofmann, set off on a voyage into the complete unknown. For better or worse, LSD had come to America in 1949 and had embarked on a strange trip of its own. Academic researchers would study it in search of knowledge that would benefit all mankind. Intelligence agencies, particularly the CIA, would subsidize and shape the form of much of this work to learn how the drug could be used to break the will of enemy agents, unlock secrets in the minds of trained spies, and otherwise manipulate human behavior. These two strains - of helping people and of controlling them - would coexist rather comfortably through the 1950s. Then, in the 1960s, LSD would escape from the closed world of scholar and spy, and it would play a major role in causing a cultural upheaval that would have an impact both on global politics and on intimate personal beliefs. The trip would wind up - to borrow some hyperbole from the musical Hair - with "the youth of America on LSD."

The counterculture generation was not yet out of the nursery, however, when Bob Hyde went tripping: Hyde himself would not become a secret CIA consultant for several years. The CIA and the military intelligence agencies were just setting out on their quest for drugs and other exotic methods to take possession of people's minds. The ancient desire to control enemies through magical spells and potions had come alive again, and several offices within the CIA competed to become the head controllers. Men from the Office of Security's ARTICHOKE program were struggling - as had OSS before them - to find a truth drug or hypnotic method that would aid in interrogation. Concurrently, the Technical Services Staff (TSS) was investigating in much greater depth the whole area of applying chemical and biological warfare (CBW) to covert operations. TSS was the lineal descendent of Stanley Lovell's Research and Development unit in OSS, and its officials kept alive much of the excitement and urgency of the World War II days when Lovell had tried to bring out the Peck's Bad Boy in American scientists. Specialists from TSS furnished backup equipment for secret operations: false papers, bugs, taps, suicide pills, explosive seashells, transmitters hidden in false teeth, cameras in tobacco pouches, invisible inks, and the like. In later years, these gadget wizards from TSS would become known for supplying some of history's more ludicrous landmarks, such as Howard Hunt's ill-fitting red wig; but in the early days of the CIA, they gave promise of transforming the spy world.

Within TSS, there existed a Chemical Division with functions that few others - even in TSS - knew about. These had to do with using chemicals (and germs) against specific people. From 1951 to 1956, the years when the CIA's interest in LSD peaked, Sidney Gottlieb, a native of the Bronx with a Ph.D. in chemistry from Cal Tech, headed this division. (And for most of the years until 1973, he would oversee TSS's behavioral programs from one job or another.) Only 33 years old when he took over the Chemical Division, Gottlieb had managed to overcome a pronounced stammer and a clubfoot to rise through Agency ranks. Described by several acquaintances as a "compensator," Gottlieb prided himself on his ability, despite his obvious handicaps, to pursue his cherished hobby, folk dancing. On returning from secret missions overseas, he invariably brought back a new step that he would dance with surprising grace. He could call out instructions for the most complicated dances without a break in his voice, infecting others with enthusiasm. A man of unorthodox tastes, Gottlieb lived in a former slave cabin that he had remodeled himself - with his wife, the daughter of Presbyterian missionaries in India, and his four children. Each morning, he rose at 5:30 to milk the goats he kept on his 15 acres outside Washington. The Gottliebs drank only goat's milk, and they made their own cheese. They also raised Christmas trees which they sold to the outside world. Greatly respected by his former colleagues, Gottlieb, who refused to be interviewed for this book, is described as a humanist, a man of intellectual humility and strength, willing to carry out, as one ex-associate puts it, "the tough things that had to be done." This associate fondly recalls, "When you watched him, you gained more and more respect because he was willing to work so hard to get an idea across. He left himself totally exposed. It was more important for us to get the idea than for him not to stutter." One idea he got across was that the Agency should investigate the potential use of the obscure new drug, LSD, as a spy weapon.

At the top ranks of the Clandestine Services (officially called the Directorate of Operations but popularly known as the "dirty tricks department"), Sid Gottlieb had a champion who appreciated his qualities, Richard Helms. For two decades, Gottlieb would move into progressively higher positions in the wake of Helms' climb to the highest position in the Agency. Helms, the tall, smooth "preppie," apparently liked the way the Jewish chemist, who had started out at Manhattan's City College, could thread his way through complicated technical problems and make them understandable to nonscientists. Gottlieb was loyal and he followed orders. Although many people lay in the chain of command between the two men, Helms preferred to avoid bureaucratic niceties by dealing directly with Gottlieb.

On April 3, 1953, Helms proposed to Director Allen Dulles that the CIA set up a program under Gottlieb for "covert use of biological and chemical materials." Helms made clear that the Agency could use these methods in "present and future clandestine operations" and then added, "Aside from the offensive potential, the development of a comprehensive capability in this field ... gives us a thorough knowledge of the enemy's theoretical potential, thus enabling us to defend ourselves against a foe who might not be as restrained in the use of these techniques as we are." Once again, as it would throughout the history of the behavioral programs, defense justified offense. Ray Cline, often a bureaucratic rival of Helms, notes the spirit in which the future Director pushed this program: "Helms fancied himself a pretty tough cookie. It was fashionable among that group to fancy they were rather impersonal about dangers, risks, and human life. Helms would think it sentimental and foolish to be against something like this."

On April 13, 1953 - the same day that the Pentagon announced that any U.S. prisoner refusing repatriation in Korea would be listed as a deserter and shot if caught - Allen Dulles approved the program, essentially as put forth by Helms. Dulles took note of the "ultra-sensitive work" involved and agreed that the project would be called MKULTRA.[2] He approved an initial budget of $300,000, exempted the program from normal CIA financial controls, and allowed TSS to start up research projects "without the signing of the usual contracts or other written agreements." Dulles ordered the Agency's bookkeepers to pay the costs blindly on the signatures of Sid Gottlieb and Willis Gibbons, a former U.S. Rubber executive who headed TSS.

As is so often the case in government, the activity that Allen Dulles approved with MKULTRA was already under way, even before he gave it a bureaucratic structure. Under the code name MKDELTA, the Clandestine Services had set up procedures the year before to govern the use of CBW products. (MKDELTA now became the operational side of MKULTRA.) Also in 1952, TSS had made an agreement with the Special Operations Division (SOD) of the Army's biological research center at Fort Detrick, Maryland whereby SOD would produce germ weapons for the CIA's use (with the program called MKNAOMI). Sid Gottlieb later testified that the purpose of these programs was "to investigate whether and how it was possible to modify an individual's behavior by covert means. The context in which this investigation was started was that of the height of the

Cold War with the Korean War just winding down; with the CIA organizing its resources to liberate Eastern Europe by paramilitary means; and with the threat of Soviet aggression very real and tangible, as exemplified by the recent Berlin airlift" (which occurred in 1948).

In the early days of MKULTRA, the roughly six TSS professionals who worked on the program spent a good deal of their time considering the possibilities of LSD.[3] "The most fascinating thing about it," says one of them, "was that such minute quantities had such a terrific effect." Albert Hofmann had gone off into another world after swallowing less than 1/100,000 of an ounce. Scientists had known about the mind-altering qualities of drugs like mescaline since the late nineteenth century, but LSD was several thousand times more potent. Hashish had been around for millennia, but LSD was roughly a million times stronger (by weight). A two-suiter suitcase could hold enough LSD to turn on every man, woman, and child in the United States. "We thought about the possibility of putting some in a city water supply and having the citizens wander around in a more or less happy state, not terribly interested in defending themselves," recalls the TSS man. But incapacitating such large numbers of people fell to the Army Chemical Corps, which also tested LSD and even stronger hallucinogens. The CIA was concentrating on individuals. TSS officials understood that LSD distorted a person's sense of reality, and they felt compelled to learn whether it could alter someone's basic loyalties. Could the CIA make spies out of tripping Russians - or vice versa? In the early 1950s, when the Agency developed an almost desperate need to know more about LSD, almost no outside information existed on the subject. Sandoz had done some clinical studies, as had a few other places, including Boston Psychopathic, but the work generally had not moved much beyond the horse-and-buggy stage. The MKULTRA team had literally hundreds of questions about LSD's physiological, psychological, chemical, and social effects. Did it have any antidotes? What happened if it were combined with other drugs? Did it affect everyone the same way? What was the effect of doubling the dose? And so on.

TSS first sought answers from academic researchers, who, on the whole, gladly cooperated and let the Agency pick their brains. But CIA officials realized that no one would undertake a quick and systematic study of the drug unless the Agency itself paid the bill. Almost no government or private money was then available for what had been dubbed "experimental psychiatry." Sandoz wanted the drug tested, for its own commercial reasons, but beyond supplying it free to researchers, it would not assume the costs. The National Institutes of Mental Health had an interest in LSD's relationship to mental illness, but CIA officials wanted to know how the drug affected normal people, not sick ones. Only the military services, essentially for the same reasons as the CIA, were willing to sink much money into LSD, and the Agency men were not about to defer to them. They chose instead to take the lead - in effect to create a whole new field of research.

Suddenly there was a huge new market for grants in academia, as Sid Gottlieb and his aides began to fund LSD projects at prestigious institutions. The Agency's LSD pathfinders can be identified: Bob Hyde's group at Boston Psychopathic, Harold Abramson at Mt. Sinai Hospital and Columbia University in New York, Carl Pfeiffer at the University of Illinois Medical School, Harris Isbell of the NIMH-sponsored Addiction Research Center in Lexington, Kentucky, Louis Jolyon West at the University of Oklahoma, and Harold Hodge's group at the University of Rochester. The Agency disguised its involvement by passing the money through two conduits: the Josiah Macy, Jr. Foundation, a rich establishment institution which served as a cutout (intermediary) only for a year or two, and the Geschickter Fund for Medical Research, a Washington, D.C. family foundation, whose head, Dr. Charles Geschickter, provided the Agency with a variety of services for more than a decade. Reflexively, TSS officials felt they had to keep the CIA connection secret. They could only "assume," according to a 1955 study, that Soviet scientists understood the drug's "strategic importance" and were capable of making it themselves. They did not want to spur the Russians into starting their own LSD program or into devising countermeasures.

The CIA's secrecy was also clearly aimed at the folks back home. As a 1963 Inspector General's report stated, "Research in the manipulation of human behavior is considered by many authorities in medicine and related fields to be professionally unethical"; therefore, openness would put "in jeopardy" the reputations of the outside researchers. Moreover, the CIA Inspector General declared that disclosure of certain MKULTRA activities could result in "serious adverse reaction" among the American public.

At Boston Psychopathic, there were various levels of concealment. Only Bob Hyde and his boss, the hospital superintendent, knew officially that the CIA was funding the hospital's LSD program from 1952 on, to the tune of about $40,000 a year. Yet, according to another member of the Hyde group, Dr. DeShon, all senior staff understood where the money really came from. "We agreed not to discuss it," says DeShon. "I don't see any objection to this. We never gave it to anyone without his consent and without explaining it in detail." Hospital officials told the volunteer subjects something about the nature of the experiments but nothing about their origins or purpose. None of the subjects had any idea that the CIA was paying for the probing of their minds and would use the results for its own purposes; most of the staff was similarly ignorant.

Like Hyde, almost all the researchers tried LSD on themselves. Indeed, many believed they gained real insight into what it felt like to be mentally ill, useful knowledge for health professionals who spent their lives treating people supposedly sick in the head. Hyde set up a multidisciplinary program - virtually unheard of at the time - that brought together psychiatrists, psychologists, and physiologists. As subjects, they used each other, hospital patients, and volunteers - mostly students - from the Boston area. They worked through a long sequence of experiments that served to isolate variable after variable. Palming themselves off as foundation officials, the men from MKULTRA frequently visited to observe and suggest areas of future research. One Agency man, who himself tripped several times under Hyde's general supervision, remembers that he and his colleagues would pass on a nugget that another contractor like Harold Abramson had gleaned and ask Hyde to perform a follow-up test that might answer a question of interest to the Agency. Despite these tangents, the main body of research proceeded in a planned and orderly fashion. The researchers learned that while some subjects seemed to become schizophrenic, many others did not. Surprisingly, true schizophrenics showed little reaction at all to LSD, unless given massive doses. The Hyde group found out that the quality of a person's reaction was determined mainly by the person's basic personality structure (set) and the environment (setting) in which he or she took the drug. The subject's expectation of what would happen also played a major part. More than anything else, LSD tended to intensify the subject's existing characteristics - often to extremes. A little suspicion could grow into major paranoia, particularly in the company of people perceived as threatening.

Unbeknownst to his fellow researchers, the energetic Dr. Hyde also advised the CIA on using LSD in covert operations. A CIA officer who worked with him recalls: "The idea would be to give him the details of what had happened [with a case], and he would speculate. As a sharp M.D. in the old-school sense, he would look at things in ways that a lot of recent bright lights couldn't get.... He had a good sense of makedo." The Agency paid Hyde for his time as a consultant, and TSS officials eventually set aside a special MKULTRA subproject as Hyde's private funding mechanism. Hyde received funds from yet another MKULTRA subproject that TSS men created for him in 1954, so he could serve as a cutout for Agency purchases of rare chemicals. His first buy was to be $32,000 worth of corynanthine, a possible antidote to LSD, that would not be traced to the CIA.

Bob Hyde died in 1976 at the age of 66, widely hailed as a pacesetter in mental health. His medical and intelligence colleagues speak highly of him both personally and professionally. Like most of his generation, he apparently considered helping the CIA a patriotic duty. An Agency officer states that Hyde never raised doubts about his covert work. "He wouldn't moralize. He had a lot of trust in the people he was dealing with [from the CIA]. He had pretty well reached the conclusion that if they decided to do something [operationally], they had tried whatever else there was and were willing to risk it."

Most of the CIA's academic researchers published articles on their work in professional journals, but those long, scholarly reports often gave an incomplete picture of the research. In effect, the scientists would write openly about how LSD affects a patient's pulse rate, but they would tell only the CIA how the drug could be used to ruin that patient's marriage or memory. Those researchers who were aware of the Agency's sponsorship seldom published anything remotely connected to the instrumental and rather unpleasant questions the MKULTRA men posed for investigation. That was true of Hyde and of Harold Abramson, the New York allergist who became one of the first Johnny Appleseeds of LSD by giving it to a number of his distinguished colleagues. Abramson documented all sorts of experiments on topics like the effects of LSD on Siamese fighting fish and snails,[4] but he never wrote a word about one of his early LSD assignments from the Agency. In a 1953 document, Sid Gottlieb listed subjects he expected Abramson to investigate with the $85,000 the Agency was furnishing him. Gottlieb wanted "operationally pertinent materials along the following lines: a. Disturbance of Memory; b. Discrediting by Aberrant Behavior; c. Alteration of Sex Patterns; d. Eliciting of Information; e. Suggestibility; f. Creation of Dependence."

Dr. Harris Isbell, whose work the CIA funded through Navy cover with the approval of the Director of the National Institutes of Health, published his principal findings, but he did not mention how he obtained his subjects. As Director of the Addiction Research Center at the huge Federal drug hospital in Lexington, Kentucky, he had access to a literally captive population. Inmates heard on the grapevine that if they volunteered for Isbell's program, they would be rewarded either in the drug of their choice or in time off from their sentences. Most of the addicts chose drugs - usually heroin or morphine of a purity seldom seen on the street. The subjects signed an approval form, but they were not told the names of the experimental drugs or the probable effects. This mattered little, since the "volunteers" probably would have granted their informed consent to virtually anything to get hard drugs.

Given Isbell's almost unlimited supply of subjects, TSS officials used the Lexington facility as a place to make quick tests of promising but untried drugs and to perform specialized experiments they could not easily duplicate elsewhere. For instance, Isbell did one study for which it would have been impossible to attract student volunteers. He kept seven men on LSD for 77 straight days.[5] Such an experiment is as chilling as it is astonishing - both to lovers and haters of LSD. Nearly 20 years after Dr. Isbell's early work, counterculture journalist Hunter S. Thompson delighted and frightened his readers with accounts of drug binges lasting a few days, during which Thompson felt his brain boiling away in the sun, his nerves wrapping around enormous barbed wire forts, and his remaining faculties reduced to their reptilian antecedents. Even Thompson would shudder at the thought of 77 days straight on LSD, and it is doubtful he would joke about the idea. To Dr. Isbell, it was just another experiment. "I have had seven patients who have now been taking the drug for more than 42 days," he wrote in the middle of the test, which he called "the most amazing demonstration of drug tolerance I have ever seen." Isbell tried to "break through this tolerance" by giving triple and quadruple doses of LSD to the inmates.

Filled with intense curiosity, Isbell tried out a wide variety of unproven drugs on his subjects. Just as soon as a new batch of scopolamine, rivea seeds, or bufotenine arrived from the CIA or NIMH, he would start testing. His relish for the task occasionally shone through the dull scientific reports. "I will write you a letter as soon as I can get the stuff into a man or two," he informed his Agency contact.

No corresponding feeling shone through for the inmates, however. In his few recorded personal comments, he complained that his subjects tended to be afraid of the doctors and were not as open in describing their experiences as the experimenters would have wished. Although Isbell made an effort to "break through the barriers" with the subjects, who were nearly all black drug addicts, Isbell finally decided "in all probability, this type of behavior is to be expected with patients of this type." The subjects have long since scattered, and no one apparently has measured the aftereffects of the more extreme experiments on them.

One subject who could be found spent only a brief time with Dr. Isbell. Eddie Flowers was 19 years old and had been in Lexington for about a year when he signed up for Isbell's program. He lied about his age to get in, claiming he was 21. All he cared about was getting some drugs. He moved into the experimental wing of the hospital where the food was better and he could listen to music. He loved his heroin but knew nothing about drugs like LSD. One day he took something in a graham cracker. No one ever told him the name, but his description sounds like it made him trip - badly, to be sure. "It was the worst shit I ever had," he says. He hallucinated and suffered for 16 or 17 hours. "I was frightened. I wouldn't take it again." Still, Flowers earned enough "points" in the experiment to qualify for his "payoff in heroin. All he had to do was knock on a little window down the hall. This was the drug bank. The man in charge kept a list of the amount of the hard drug each inmate had in his account. Flowers just had to say how much he wanted to withdraw and note the method of payment. "If you wanted it in the vein, you got it there," recalls Flowers who now works in a Washington, D.C. drug rehabilitation center.

Dr. Isbell refuses all request for interviews. He did tell a Senate subcommittee in 1975 that he inherited the drug payoff system when he came to Lexington and that "it was the custom in those days.... The ethical codes were not so highly developed, and there was a great need to know in order to protect the public in assessing the potential use of narcotics.... I personally think we did a very excellent job."

For every Isbell, Hyde, or Abramson who did TSS contract work, there were dozens of others who simply served as casual CIA informants, some witting and some not. Each TSS project officer had a skull session with dozens of recognized experts several times a year. "That was the only way a tiny staff like Sid Gottlieb's could possibly keep on top of the burgeoning behavioral sciences," says an ex-CIA official. "There would be no way you could do it by library research or the Ph.D. dissertation approach." The TSS men always asked their contacts for the names of others they could talk to, and the contacts would pass them on to other interesting scientists.

In LSD research, TSS officers benefited from the energetic intelligence gathering of their contractors, particularly Harold Abramson. Abramson talked regularly to virtually everyone interested in the drug, including the few early researchers not funded by the Agency or the military, and he reported his findings to TSS. In addition, he served as reporting secretary of two conference series sponsored by the Agency's sometime conduit, the Macy Foundation. These series each lasted over five year periods in the 1950s; one dealt with "Problems of Consciousness" and the other with "Neuropharmacology." Held once a year in the genteel surroundings of the Princeton Inn, the Macy Foundation conferences brought together TSS's (and the military's) leading contractors, as part of a group of roughly 25 with the multidisciplinary background that TSS officials so loved. The participants came from all over the social sciences and included such luminaries as Margaret Mead and Jean Piaget. The topics discussed usually mirrored TSS's interests at the time, and the conferences served as a spawning ground for ideas that allowed researchers to engage in some healthy cross-fertilization.

Beyond the academic world, TSS looked to the pharmaceutical companies as another source on drugs - and for a continuing supply of new products to test. TSS's Ray Treichler handled the liaison function, and this secretive little man built up close relationships with many of the industry's key executives. He had a particular knack for convincing them he would not reveal their trade secrets. Sometimes claiming to be from the Army Chemical Corps and sometimes admitting his CIA connection, Treichler would ask for samples of drugs that were either highly poisonous, or, in the words of the onetime director of research of a large company, "caused hypertension, increased blood pressure, or led to other odd physiological activity."

Dealing with American drug companies posed no particular problems for TSS. Most cooperated in any way they could. But relations with Sandoz were more complicated. The giant Swiss firm had a monopoly on the Western world's production of LSD until 1953. Agency officials feared that Sandoz would somehow allow large quantities to reach the Russians. Since information on LSD's chemical structure and effects was publicly available from 1947 on, the Russians could have produced it any time they felt it worthwhile. Thus, the Agency's phobia about Sandoz seems rather irrational, but it unquestionably did exist.

On two occasions early in the Cold War, the entire CIA hierarchy went into a dither over reports that Sandoz might allow large amounts of LSD to reach Communist countries. In 1951 reports came in through military channels that the Russians had obtained some 50 million doses from Sandoz. Horrendous visions of what the Russians might do with such a stockpile circulated in the CIA, where officials did not find out the intelligence was false for several years. There was an even greater uproar in 1953 when more reports came in, again through military intelligence, that Sandoz wanted to sell the astounding quantity of 10 kilos (22 pounds) of LSD enough for about 100 million doses - on the open market.

A top-level coordinating committee which included CIA and Pentagon representatives unanimously recommended that the Agency put up $240,000 to buy it all. Allen Dulles gave his approval, and off went two CIA representatives to Switzerland, presumably with a black bag full of cash. They met with the president of Sandoz and other top executives. The Sandoz men stated that the company had never made anything approaching 10 kilos of LSD and that, in fact, since the discovery of the drug 10 years before, its total production had been only 40 grams (about 11/2 ounces).[6] The manufacturing process moved quite slowly at that time because Sandoz used real ergot, which could not be grown in large quantities. Nevertheless, Sandoz executives, being good Swiss businessmen, offered to supply the U.S. Government with 100 grams weekly for an indefinite period, if the Americans would pay a fair price. Twice the Sandoz president thanked the CIA men for being willing to take the nonexistent 10 kilos off the market. While he said the company now regretted it had ever discovered LSD in the first place, he promised that Sandoz would not let the drug fall into communist hands. The Sandoz president mentioned that various Americans had in the past made "covert and sideways" approaches to Sandoz to find out about LSD, and he agreed to keep the U.S. Government informed of all future production and shipping of the drug. He also agreed to pass on any intelligence about Eastern European interest in LSD. The Sandoz executives asked only that their arrangement with the CIA be kept "in the very strictest confidence."

All around the world, the CIA tried to stay on top of the LSD supply. Back home in Indianapolis, Eli Lilly & Company was even then working on a process to synthesize LSD. Agency officials felt uncomfortable having to rely on a foreign company for their supply, and in 1953 they asked Lilly executives to make them up a batch, which the company subsequently donated to the government. Then, in 1954, Lilly scored a major breakthrough when its researchers worked out a complicated 12- to 15-step process to manufacture first lysergic acid (the basic building block) and then LSD itself from chemicals available on the open market. Given a relatively sophisticated lab, a competent chemist could now make LSD without a supply of the hard-to-grow ergot fungus. Lilly officers confidentially informed the government of their triumph. They also held an unprecedented press conference to trumpet their synthesis of lysergic acid, but they did not publish for another five years their success with the closely related LSD.

TSS officials soon sent a memo to Allen Dulles, explaining that the Lilly discovery was important because the government henceforth could buy LSD in "tonnage quantities," which made it a potential chemical-warfare agent. The memo writer pointed out, however, that from the MKULTRA point of view, the discovery made no difference since TSS was working on ways to use the drug only in small-scale covert operations, and the Agency had no trouble getting the limited amounts it needed. But now the Army Chemical Corps and the Air Force could get their collective hands on enough LSD to turn on the world.

Sharing the drug with the Army here, setting up research programs there, keeping track of it everywhere, the CIA generally presided over the LSD scene during the 1950s. To be sure, the military services played a part and funded their own research programs.[7] So did the National Institutes of Health, to a lesser extent. Yet both the military services and the NIH allowed themselves to be co-opted by the CIA - as funding conduits and intelligence sources. The Food and Drug Administration also supplied the Agency with confidential information on drug testing. Of the Western world's two LSD manufacturers, one - Eli Lilly - gave its entire (small) supply to the CIA and the military. The other - Sandoz - informed Agency representatives every time it shipped the drug. If somehow the CIA missed anything with all these sources, the Agency still had its own network of scholar-spies, the most active of whom was Harold Abramson who kept it informed of all new developments in the LSD field. While the CIA may not have totally cornered the LSD market in the 1950s, it certainly had a good measure of control - the very power it sought over human behavior.

Sid Gottlieb and his colleagues at MKULTRA soaked up pools of information about LSD and other drugs from all outside sources, but they saved for themselves the research they really cared about: operational testing. Trained in both science and espionage, they believed they could bridge the huge gap between experimenting in the laboratory and using drugs to outsmart the enemy. Therefore the leaders of MKULTRA initiated their own series of drug experiments that paralleled and drew information from the external research. As practical men of action, unlimited by restrictive academic standards, they did not feel the need to keep their tests in strict scientific sequence. They wanted results now - not next year. If a drug showed promise, they felt no qualms about trying it out operationally before all the test results came in. As early as 1953, for instance, Sid Gottlieb went overseas with a supply of a hallucinogenic drug - almost certainly LSD. With unknown results, he arranged for it to be slipped to a speaker at a political rally, presumably to see if it would make a fool of him.

These were freewheeling days within the CIA - then a young agency whose bureaucratic arteries had not started to harden. The leaders of MKULTRA had high hopes for LSD. It appeared to be an awesome substance, whose advent, like the ancient discovery of fire, would bring out primitive responses of fear and worship in people. Only a speck of LSD could take a strongwilled man and turn his most basic perceptions into willowy shadows. Time, space, right, wrong, order, and the notion of what was possible all took on new faces. LSD was a frightening weapon, and it took a swashbuckling boldness for the leaders of MKULTRA to prepare for operational testing the way they first did: by taking it themselves. They tripped at the office. They tripped at safehouses, and sometimes they traveled to Boston to trip under Bob Hyde's penetrating gaze. Always they observed, questioned, and analyzed each other. LSD seemed to remove inhibitions, and they thought they could use it to find out what went on in the mind underneath all the outside acts and pretensions. If they could get at the inner self, they reasoned, they could better manipulate a person - or keep him from being manipulated.

The men from MKULTRA were trying LSD in the early 1950s - when Stalin lived and Joe McCarthy raged. It was a foreboding time, even for those not professionally responsible for doomsday poisons. Not surprisingly, Sid Gottlieb and colleagues who tried LSD did not think of the drug as something that might enhance creativity or cause transcendental experiences. Those notions would not come along for years. By and large, there was thought to be only one prevailing and hardheaded version of reality, which was "normal," and everything else was "crazy." An LSD trip made people temporarily crazy, which meant potentially vulnerable to the CIA men (and mentally ill, to the doctors). The CIA experimenters did not trip for the experience itself, or to get high, or to sample new realities. They were testing a weapon; for their purposes, they might as well have been in a ballistics lab.

Despite this prevailing attitude in the Agency, at least one MKULTRA pioneer recalls that his first trip expanded his conception of reality: "I was shaky at first, but then I just experienced it and had a high. I felt that everything was working right. I was like a locomotive going at top efficiency. Sure there was stress, but not in a debilitating way. It was like the stress of an engine pulling the longest train it's ever pulled." This CIA veteran describes seeing all the colors of the rainbow growing out of cracks in the sidewalk. He had always disliked cracks as signs of imperfection, but suddenly the cracks became natural stress lines that measured the vibrations of the universe. He saw people with blemished faces, which he had previously found slightly repulsive. "I had a change of values about faces," he says. "Hooked noses or crooked teeth would become beautiful for that person. Something had turned loose in me, and all I had done was shift my attitude. Reality hadn't changed, but I had. That was all the difference in the world between seeing something ugly and seeing truth and beauty."

At the end of this day of his first trip, the CIA man and his colleagues had an alcohol party to help come down. "I had a lump in my throat," he recalls wistfully. Although he had never done such a thing before, he wept in front of his coworkers. "I didn't want to leave it. I felt I would be going back to a place where I wouldn't be able to hold on to this kind of beauty. I felt very unhappy. The people who wrote the report on me said I had experienced depression, but they didn't understand why I felt so bad. They thought I had had a bad trip."

This CIA man says that others with his general personality tended to enjoy themselves on LSD, but that the stereotypical CIA operator (particularly the extreme counterintelligence type who mistrusts everyone and everything) usually had negative reactions. The drug simply exaggerated his paranoia. For these operators, the official notes, "dark evil things would begin to lurk around," and they would decide the experimenters were plotting against them.

The TSS team understood it would be next to impossible to allay the fears of this ever-vigilant, suspicious sort, although they might use LSD to disorient or generally confuse such a person. However, they toyed with the idea that LSD could be applied to better advantage on more trusting types. Could a clever foe "re-educate" such a person with a skillful application of LSD? Speculating on this question, the CIA official states that while under the influence of the drug, "you tend to have a more global view of things. I found it awfully hard when stoned to maintain the notion: I am a U.S. citizen - my country right or wrong.... You tend to have these good higher feelings. You are more open to the brotherhood-of-man idea and more susceptible to the seamy sides of your own society.... I think this is exactly what happened during the 1960s, but it didn't make people more communist. It just made them less inclined to identify with the U.S. They took a plague-on-both-your-houses position."

As to whether his former colleagues in TSS had the same perception of the LSD experience, the man replies, "I think everybody understood that if you had a good trip, you had a kind of above-it-all look into reality. What we subsequently found was that when you came down, you remembered the experience, but you didn't switch identities. You really didn't have that kind of feeling. You weren't as suspicious of people. You listened to them, but you also saw through them more easily and clearly. We decided that this wasn't the kind of thing that was going to make a guy into a turncoat to his own country. The more we worked with it, the less we became convinced this was what the communists were using for brainwashing."

The early LSD tests - both outside and inside the Agency - had gone well enough that the MKULTRA scientists moved forward to the next stage on the road to "field" use: They tried the drug out on people by surprise. This, after all, would be the way an operator would give - or get - the drug. First they decided to spring it on each other without warning. They agreed among themselves that a coworker might slip it to them at any time. (In what may be an apocryphal story, a TSS staff man says that one of his former colleagues always brought his own bottle of wine to office parties and carried it with him at all times.) Unwitting doses became an occupational hazard.

MKULTRA men usually took these unplanned trips in stride, but occasionally they turned nasty. Two TSS veterans tell the story of a coworker who drank some LSDlaced coffee during his morning break. Within an hour, states one veteran, "he sort of knew he had it, but he couldn't pull himself together. Sometimes you take it, and you start the process of maintaining your composure. But this grabbed him before he was aware, and it got away from him." Filled with fear, the CIA man fled the building that then housed TSS, located on the edge of the Mall near Washington's great monuments. Having lost sight of him, his colleagues searched frantically, but he managed to escape. The hallucinating Agency man worked his way across one of the Potomac bridges and apparently cut his last links with rationality. "He reported afterwards that every automobile that came by was a terrible monster with fantastic eyes, out to get him personally," says the veteran. "Each time a car passed, he would huddle down against the parapet, terribly frightened. It was a real horror trip for him. I mean, it was hours of agony. It was like a dream that never stops - with someone chasing you."

After about an hour and a half, the victim's coworkers found him on the Virginia side of the Potomac, crouched under a fountain, trembling. "It was awfully hard to persuade him that his friends were his friends at that point," recalls the colleague. "He was alone in the world, and everyone was hostile. He'd become a full-blown paranoid. If it had lasted for two weeks, we'd have plunked him in a mental hospital." Fortunately for him, the CIA man came down by the end of the day. This was not the first, last, or most tragic bad trip in the Agency's testing program.[8]

By late 1953, only six months after Allen Dulles had formally created MKULTRA, TSS officials were already well into the last stage of their research: systematic use of LSD on "outsiders" who had no idea they had received the drug. These victims simply felt their moorings slip away in the midst of an ordinary day, for no apparent reason, and no one really knew how they would react.

Sid Gottlieb was ready for the operational experiments. He considered LSD to be such a secret substance that he gave it a private code name ("serunim") by which he and his colleagues often referred to the drug, even behind the CIA's heavily guarded doors. In retrospect, it seems more than bizarre that CIA officials - men responsible for the nation's intelligence and alertness when the hot and cold wars against the communists were at their peak - would be sneaking LSD into each other's coffee cups and thereby subjecting themselves to the unknown frontiers of experimental drugs. But these side trips did not seem to change the sense of reality of Gottlieb or of high CIA officials, who took LSD on several occasions. The drug did not transform Gottlieb out of the mind set of a master scientist-spy, a protégé of Richard Helms in the CIA's inner circle. He never stopped milking his goats at 5:30 every morning.

The CIA leaders' early achievements with LSD were impressive. They had not invented the drug, but they had gotten in on the American ground floor and done nearly everything else. They were years ahead of the scientific literature - l*et al*one the public - and spies win by being ahead. They had monopolized the supply of LSD and dominated the research by creating much of it themselves. They had used money and other blandishments to build a network of scientists and doctors whose work they could direct and turn to their own use. All that remained between them and major espionage successes was the performance of the drug in the field.

That, however, turned out to be a considerable stumbling block. LSD had an incredibly powerful effect on people, but not in ways the CIA could predict or control.

Notes 4

The description of Robert Hyde's first trip came from interviews with Dr. Milton Greenblatt, Dr. J. Herbert DeShon, and a talk by Max Rinkel at the 2nd Macy Conference on Neuropharmacology, pp. 235-36, edited by Harold A. Abramson, 1955: Madison Printing Company.

The descriptions of TSS and Sidney Gottlieb came from interviews with Ray Cline, John Stockwell, about 10 other ex-CIA officers, and other friends of Gottlieb.

Memos quoted on the early MKULTRA program include Memorandum from ADDP Helms to DCI Dulles, 4/3/53, Tab A, pp. 1-2 (quoted in Church Committee Report, Book I); APF A-1, April 13, 1953, Memorandum for Deputy Director (Administration, Subject: Project MKULTRA - Extremely Sensitive Research and Development Program; #A/B,I,64/6, 6 February 1952, Memorandum for the Record, Subject: Contract with [deleted]

#A/B,I,64/29, undated, Memorandum for Technical Services Staff, Subject: Alcohol Antagonists and Accelerators, Research and Development Project. The Gottlieb quote is from Hearing before the Subcommittee on Health and Scientific Research of the Senate Committee on Human Resources, September 21, 1977, p. 206.

The background data on LSD came particularly from The Beyond Within: The LSD Story by Sidney Cohen (New York: Atheneum,1972). Other sources included Origins of Psychopharmacology: From CPZ to LSD by Anne E. Caldwell (Springfield, III.: Charles C. Thomas, 1970) and Document 352, "An OSI Study of the Strategic Medical Importance of LSD-25," 30 August 1955.

TSS's use of outside researchers came from interviews with four former TSSers. MKULTRA Subprojects 8, 10, 63, and 66 described Robert Hyde's work. Subprojects 7, 27, and 40 concerned Harold Abramson. Hodge's work was in subprojects 17 and 46. Carl Pfeiffer's Agency connection, along with Hyde's, Abramson's, and Isbell's, was laid out by Lyman B. Kirkpatrick, Memorandum for the Record, 1 December 1953, Subject: Conversation with Dr. Willis Gibbons of TSS re Olson Case (found at p. 1030, Kennedy Subcommittee 1975 Biomedical and Behavioral Research Hearings). Isbell's testing program was also described at those hearings, as it was in Document # 14, 24 July, 1953, Memo For: Liaison & Security Officer/TSS, Subject #71 An Account of the Chemical Division's Contacts in the National Institute of Health; Document #37, 14 July 1954, subject [deleted]; and Document # 41,31 August,1956, subject; trip to Lexington, Ky.,21-23 August 1956. Isbell's program was further described in a "Report on ADAMHA Involvement in LSD Research," found at p. 993 of 1975 Kennedy subcommittee hearings. The firsthand account of the actual testing came from an interview with Edward M. Flowers, Washington, D.C.

The section on TSS's noncontract informants came from interviews with TSS sources, reading the proceedings of the Macy Conferences on "Problems of Consciousness" and "Neuropharmacology," and interviews with several participants including Sidney Cohen, Humphrey Osmond, and Hudson Hoagland.

The material on CIA's relations with Sandoz and Eli Lilly came from Document #24, 16 November, 1953, Subject: ARTICHOKE Conference; Document #268, 23 October, 1953, Subject: Meeting in Director's Office at 1100 hours on 23 October with Mr. Wisner and [deleted]; Document # 316,6 January,1954, Subject: Lysergic Acid Diethylamide (LSD-25); and Document #338, 26 October 1954, Subject: Potential Large Scale Availability of LSD through newly discovered synthesis by [deleted]; interviews with Sandoz and Lilly former executives; interviews with TSS sources; and Sidney Gottlieb's testimony before Kennedy subcommittee, 1977, p. 203.

Henry Beecher's US government connections were detailed in his private papers, in a report on the Swiss-LSD death to the CIA at p. 396, Church Committee Report, Book I, and in interviews with two of his former associates.

The description of TSS's internal testing progression comes from interviews with former staff members. The short reference to Sid Gottlieb's arranging for LSD to be given a speaker at a political rally comes from Document #A/B, II, 26/8, 9 June 1954, Subject: MKULTRA. Henry Beecher's report to the CIA on the Swiss suicide is found at p. 396, Church Committee Report, Book I.

Footnotes 4

1. During the 1950s, Boston Psychopathic changed its name to Massachusetts Mental Health Center, the name it bears today.
2. Pronounced M-K-ULTRA. The MK digraph simply identified it as a TSS project. As for the ULTRA part, it may have had its etymological roots in the most closely guarded Anglo-American World War II intelligence secret, the ULTRA program, which handled the cracking of German military codes. While good espionage tradecraft called for cryptonyms to have no special meaning, wartime experiences were still very much on the minds of men like Allen Dulles.
3. By no means did TSS neglect other drugs. It looked at hundreds of others from cocaine to nicotine, with special emphasis on special-purpose substances. One 1952 memo talked about the urgent operational need for a chemical "producing general listlessness and lethargy." Another mentioned finding - as TSS later did - a potion to accelerate the effects of liquor, called an "alcohol extender."
4. As happened to Albert Hofmann the first time, Abramson once unknowingly ingested some LSD, probably by swallowing water from his spiked snail tank. He started to feel bad, but with his wife's help, he finally pinpointed the cause. According to brain and dolphin expert John Lilly, who heard the story from Mrs. Abramson, Harold was greatly relieved that his discomfort was not grave. "Oh, it's nothing serious," he said. "It's just an LSD psychosis. I'll just go to bed and sleep it off."
5. Army researchers, as usual running about five years behind the CIA, became interested in the sustained use of LSD as an interrogation device during 1961 field tests (called Operation THIRD CHANCE). The Army men tested the drug in Europe on

nine foreigners and one American, a black soldier named James Thornwell, accused of stealing classified documents. While Thornwell was reacting to the drug under extremely stressful conditions, his captors threatened "to extend the state indefinitely, even to a permanent condition of insanity," according to an Army document. Thornwell is now suing the U.S. government for $30 million.

In one of those twists that Washington insiders take for granted and outsiders do not quite believe, Terry Lenzner, a partner of the same law firm seeking this huge sum for Thornwell, is the lawyer for Sid Gottlieb, the man who oversaw the 77-day trips at Lexington and even more dangerous LSD testing.

6. A 1975 CIA document clears up the mystery of how the Agency's military sources could have made such a huge error in estimating Sandoz's LSD supply (and probably also explains the earlier inaccurate report that the Russians had bought 50,000,000 doses). What happened, according to the document, was that the U.S. military attaché in Switzerland did not know the difference between a milligram (1/1,000 of a gram) and a kilogram (1,000 grams). This mix-up threw all his calculations off by a factor of 1,000,000.
7. Military security agencies supported the LSD work of such well-known researchers as Amedeo Marrazzi of the University of Minnesota and Missouri Institute of Psychiatry, Henry Beecher of Harvard and Massachusetts General Hospital, Charles Savage while he was at the Naval Medical Research Institute, James Dille of the University of Washington, Gerald Klee of the University of Maryland Medical School, Neil Burch of Baylor University (who performed later experiments for the CIA), and Paul Hoch and James Cattell of the New York State Psychiatric Institute, whose forced injections of a mescaline derivative led to the 1953 death of New York tennis professional Harold Blauer. (Dr. Cattell later told Army investigators, "We didn't know whether it was dog piss or what it was we were giving him.")
8. TSS officials had long known that LSD could be quite dangerous. In 1952, Harvard Medical School's Henry Beecher who regularly gave the Agency information on his talks with European colleagues, reported that a Swiss doctor had suffered severe depression after taking the drug and had killed herself three weeks later.

5. Concerning the Case of Dr. Frank Olsen

In November 1953, Sid Gottlieb decided to test LSD on a group of scientists from the Army Chemical Corps' Special Operations Division (SOD) at Fort Detrick in Frederick, Maryland. Although the Clandestine Services hierarchy had twice put TSS under strict notice not to use LSD without permission from above, Gottlieb must have felt that trying the drug on SOD men was not so different from giving it to his colleagues at the office. After all, officials at TSS and SOD worked intimately together, and they shared one of the darkest secrets of the Cold War: that the U.S. government maintained the capability - which it would use at times - to kill or incapacitate selected people with biological weapons. Only a handful of the highest CIA officials knew that TSS was paying SOD about $200,000 a year in return for operational systems to infect foes with disease.

Gottlieb planned to drop the LSD on the SOD men in the splendid isolation of a three-day working retreat. Twice a year, the SOD and TSS men who collaborated on MKNAOMI, their joint program, held a planning session at a remote site where they could brainstorm without interruption. On November 18, 1953, they gathered at Deep Creek Lodge, a log building in the woods of Western Maryland. It had been built as a Boy Scout camp 25 years earlier. Surrounded by the water of a mountain lake on three sides, with the peaks of the Appalachian chain looking down over the thick forest, the lodge was isolated enough for even the most security conscious spy. Only an occasional hunter was likely to wander through after the summer months.

Dr. John Schwab, who had founded SOD in 1950, Lt. Colonel Vincent Ruwet, its current chief, and Dr. Frank Olson, its temporary head earlier that year, led the Detrick group. These germ warriors came under the cover of being wildlife writers and lecturers off on a busman's holiday. They carefully removed the Fort Detrick parking stickers from their cars before setting out. Sid Gottlieb brought three coworkers from the Agency, including his deputy Robert Lashbrook.

They met in the living room of the lodge, in front of a roaring blaze in the huge walk-in fireplace. Then they split off into smaller groups for specialized meetings. The survivors among those who attended these sessions remain as tight-lipped as ever, willing to share a few details of the general atmosphere but none of the substance. However, from other sources at Fort Detrick and from government documents, the MKNAOMI research can be pieced together. It was this program that was discussed during the fateful retreat.

Under MKNAOMI, the SOD men developed a whole arsenal of toxic substances for CIA use. If Agency operators needed to kill someone in a few seconds with, say, a suicide pill, SOD provided super-deadly shellfish toxin.[1] On his ill-fated U-2 flight over the Soviet Union in 1960, Francis Gary Powers carried - and chose not to use - a drill bit coated with this poison concealed in a silver dollar. While perfect for someone anxious to die - or kill - instantly, shellfish toxin offered no time to escape and could be traced easily. More useful for assassination, CIA and SOD men decided, was botulinum. With an incubation period of 8 to 12 hours, it allowed the killer time to separate himself from the deed. Agency operators would later supply pills laced with this lethal food poison to its Mafia allies for inclusion in Fidel Castro's milkshake. If CIA officials wanted an assassination to look like a death from natural causes, they could choose from a long list of deadly diseases that normally occurred in particular countries. Thus in 1960, Clandestine Services chief Richard Bissell asked Sid Gottlieb to pick out an appropriate malady to kill the Congo's Patrice Lumumba. Gottlieb told the Senate investigators that he selected one that "was supposed to produce a disease that was ... indigenous to that area [of West Africa] and that could be fatal." Gottlieb personally carried the bacteria to the Congo, but this murderous operation was scrubbed before Lumumba could be infected. (The Congolese leader was killed shortly thereafter under circumstances that still are not clear.)

When CIA operators merely wanted to be rid of somebody temporarily, SOD stockpiled for them about a dozen diseases and toxins of varying strengths. At the relatively benign end of the SOD list stood Staph. enterotoxin, a mild form of food poisoning - mild compared to botulinum. This Staph. infection almost never killed and simply incapacitated its victim for 3 to 6 hours. Under the skilled guidance of Sid Gottlieb's wartime predecessor, Stanley Lovell, OSS had used this very substance to prevent Nazi official Hjalmar Schacht from attending an economic conference during the war. More virulent in the SOD arsenal was Venezuelan equine encephalomyelitis virus. It usually immobilized a person for 2 to 5 days and kept him in a weakened state for several more weeks. If the Agency wanted to incapacitate someone for a period of months, SOD had two different kinds of brucellosis.[2]

A former senior official at Fort Detrick was kind enough to run me through all the germs and toxins SOD kept for the CIA, listing their advantages and disadvantages. Before doing so, he emphasized that SOD was also trying to work out ways to protect U.S. citizens and installations from attack with similar substances. "You can't have a serious defense," he says, "unless someone has thought about offense." He stated that Japan made repeated biological attacks against China during World War II - which was one reason for starting the American program.[3] He knows of no use since by the Soviet Union or any other power.

According to the Detrick official, anyone contemplating use of a biological product had to consider many other factors besides toxicity and incubation period.

Can the germ be detected easily and countered with a vaccine? He notes that anthrax, a fatal disease (when inhaled) that SOD stored for CIA, has the advantage of symptoms that resemble pneumonia; similarly, Venezuelan equine encephalomyelitis can be mistaken for the grippe. While vaccines do exist for many of the stockpiled diseases, SOD was forever developing more virulent strains. "I don't know of any organism susceptible to a drug that can't be made more resistant," states the Detrick man.

Did the disease have a high degree of secondary spread? SOD preferred it not to, because these germ warfare men did not want to start epidemics - that was the job of others at Fort Detrick.

Was the organism stable? How did humidity affect it? SOD considered these and many other factors.

To the CIA, perhaps the most important question was whether it could covertly deliver the germ to infect the right person. One branch of SOD specialized in building delivery systems, the most famous of which now is the dart gun fashioned out of a .45 pistol that ex-CIA Director William Colby displayed to the world at a 1975 Senate hearing. The Agency had long been after SOD to develop a "non-discernible microbioinoculator" which could give people deadly shots that, according to a CIA document, could not be "easily detected upon a detailed autopsy." SOD also rigged up aerosol sprays that could be fired by remote control, including a fluorescent starter that was activated by turning on the light, a cigarette lighter that sprayed when lit, and an engine head bolt that shot off as the engine heated. "If you're going to infect people, the most likely way is respiratory," notes the high Detrick official. "Everybody breathes, but you might not get them to eat."

Frank Olson specialized in the airborne delivery of disease. He had been working in the field ever since 1943, when he came to Fort Detrick as one of the original military officers in the U. S. biological warfare program. Before the end of the war, he developed a painful ulcer condition that led him to seek a medical discharge from the uniformed military, but he had stayed on as a civilian. He joined SOD when it started in 1950. Obviously good at what he did, Olson served for several months as acting chief of SOD in 1952-53 but asked to be relieved when the added stress caused his ulcer to flare up. He happily returned to his lesser post as a branch chief, where he had fewer administrative duties and could spend more time in the laboratory. A lover of practical jokes, Olson was very popular among his many friends. He was an outgoing man, but, like most of his generation, he kept his inner feelings to himself. His great passion was his family, and he spent most of his spare time playing with his three kids and helping around the house. He had met his wife while they both studied at the University of Wisconsin.

Olson attended all the sessions and apparently did everything expected of him during the first two days at the lodge. After dinner on Thursday, November 19, 1953 - the same day that a Washington Post editorial decried the use of dogs in chemical experiments - Olson shared a drink of Cointreau with all but two of the men present. (One had a heart condition; the other, a reformed alcoholic, did not drink.) Unbeknownst to the SOD men, Sid Gottlieb had decided to spike the liqueur with LSD.[4]

> "To me, everyone was pretty normal," says SOD's Benjamin Wilson. "No one was aware anything had happened until Gottlieb mentioned it. [20 minutes after the drink] Gottlieb asked if we had noticed anything wrong. Everyone was aware, once it was brought to their attention." They tried to continue their discussion, but once the drug took hold, the meeting deteriorated into laughter and boisterous conversation. Two of the SOD men apparently got into an all-night philosophical conversation that had nothing to do with biological warfare. Ruwet remembers it as "the most frightening experience I ever had or hope to have." Ben Wilson recalls that "Olson was psychotic. He couldn't understand what happened. He thought someone was playing tricks on him.... One of

his favorite expressions was 'You guys are a bunch of thespians.'"

Olson and most of the others became increasingly uncomfortable and could not sleep.[5] When the group gathered in the morning, Olson was still agitated, obviously disturbed, as were several of his colleagues. The meeting had turned sour, and no one really wanted to do more business. They all straggled home during the day.

Alice Olson remembers her husband coming in before dinner that evening: "He said nothing. He just sat there. Ordinarily when he came back from a trip, he'd tell me about the things he could - what they had to eat, that sort of thing. During dinner, I said, 'It's a damned shame the adults in this family don't communicate anymore.' He said, 'Wait until the kids get to bed and I'll talk to you." Later that night, Frank Olson told his wife he had made "a terrible mistake," that his colleagues had laughed at him and humiliated him. Mrs. Olson assured him that the others were his friends, that they would not make fun of him. Still, Olson would not tell her any more. He kept his fears bottled up inside, and he shared nothing of his growing feeling that someone was out to get him. Alice Olson was accustomed to his keeping secrets. Although she realized he worked on biological warfare, they never talked about it. She had had only little glimpses of his profession. He complained about the painful shots he was always taking.[6] He almost never took a bath at home because he showered upon entering and leaving his office every day. When a Detrick employee died of anthrax (one of three fatalities in the base's 27-year history), Frank Olson told his wife the man had died of pneumonia.

Alice Olson had never even seen the building where her husband worked. Fort Detrick was built on the principle of concentric circles, with secrets concealed inside secrets. To enter the inner regions where SOD operated, one needed not only the highest security clearance but a "need to know" authorization. Her husband was not about to break out of a career of government-imposed secrecy to tell her about the TOP SECRET experiment that Sid Gottlieb had performed on him.

The Olsons spent an uncommunicative weekend together. On Sunday they sat on the davenport in their living room, holding hands - something they had not done for a long time. "It was a rotten November day," recalls Mrs. Olson. "The fog outside was so thick you could hardly see out the front door. Frank's depression was dreadful." Finally, she recalls, they packed up the three young children, and went off to the local theater. The film turned out to be Luther. "It was a very serious movie," remembers Mrs. Olson, "not a good one to see when you're depressed."

The following day, Olson appeared at 7:30 A.M. in the office of his boss, Lieutenant Colonel Ruwet, To Ruwet, Olson seemed "agitated." He told Ruwet he wanted either to quit or be fired. Taken aback, Ruwet reassured Olson that his conduct at the lodge had been "beyond reproach." Seemingly satisfied and relieved, Olson agreed to stay on and spent the rest of the day on routine SOD business. That evening, the Olsons spent their most lighthearted evening since before the retreat to Deep Creek Lodge, and they planned a farewell party for a colleague the following Saturday night.

Tuesday morning, Ruwet again arrived at his office to find a disturbed Frank Olson waiting for him. Olson said he felt "all mixed up" and questioned his own competence. He said that he should not have left the Army during the war because of his ulcer and that he lacked the ability to do his present work. After an hour, Ruwet decided Olson needed "psychiatric attention." Ruwet apparently felt that the CIA had caused Olson's problem in the first place, and instead of sending him to the base hospital, he called Gottlieb's deputy Robert Lashbrook to arrange for Olson to see a psychiatrist.

After a hurried conference, Lashbrook and Gottlieb decided to send Olson to Dr. Harold Abramson in New York. Abramson had no formal training in psychiatry and did not hold himself out to be a psychiatrist. He was an allergist and immunologist interested in treating the problems of the mind. Gottlieb chose him because he had a TOP SECRET CIA security clearance and because he had been working with LSD - under Agency contract - for several years. Gottlieb was obviously protecting his own bureaucratic position by not letting anyone outside TSS know what he had done. Having failed to observe the order to seek higher approval for LSD use, Gottlieb proceeded to violate another CIA regulation. It states, in effect, that whenever a potential flap arises that might embarrass the CIA or lead to a break in secrecy, those involved should immediately call the Office of Security. For health problems like Olson's, Security and the CIA medical office keep a long list of doctors (and psychiatrists) with TOP SECRET clearance who can provide treatment.

Gottlieb had other plans for Frank Olson, and off to New York went the disturbed SOD biochemist in the company of Ruwet and Lashbrook. Olson alternately improved and sank deeper and deeper into his feelings of depression, inadequacy, guilt, and paranoia. He began to think that the CIA was putting a stimulant like Benzedrine in his coffee to keep him awake and that it was the Agency that was out to get him. That first day in New York, Abramson saw Olson at his office. Then at 10:30 in the evening, the allergist visited Olson in his hotel room, armed with a bottle of bourbon and a bottle of the sedative Nembutal - an unusual combination for a doctor to give to someone with symptoms like Olson's.

Before Olson's appointment with Dr. Abramson the following day, he and Ruwet accompanied Lashbrook on a visit to a famous New York magician named John Mulholland, whom TSS had put under contract to prepare a manual that would apply "the magician's art to covert activities." An expert at pulling rabbits out of hats could easily find new and better ways to slip drugs into drinks, and Gottlieb signed up Mulholland to work on, among other things, "the delivery of various materials to unwitting subjects." Lashbrook thought that the magician might amuse Olson, but Olson became "highly suspicious." The group tactfully cut their visit short, and Lashbrook dropped Olson off at Abramson's office. After an hour's consultation with Abramson that afternoon the allergist gave Olson permission to return to Frederick the following day, Thanksgiving, to be with his family.

Olson, Ruwet, and Lashbrook had plane reservations for Thursday morning, so that night, in a preholiday attempt to lift spirits, they all went to see the Rodgers and Hammerstein hit musical, Me and Juliet. Olson became upset during the first act and told Ruwet that he knew people were waiting outside the theater to arrest him. Olson and Ruwet left the show at intermission, and the two old friends walked back to the Statler Hotel, near Penn Station. Later, while Ruwet slept in the next bed, Olson crept out of the hotel and wandered the streets. Gripped by the delusion that he was following Ruwet's orders, he tore up all his paper money and threw his wallet down a chute. At 5:30 A.M., Ruwet and Lashbrook found him sitting in the Statler lobby with his hat and coat on.

They checked out of the hotel and caught the plane back to Washington. An SOD driver picked Olson and Ruwet up at National Airport and started to drive them back to Frederick. As they drove up Wisconsin Avenue, Olson had the driver pull into a Howard Johnson's parking lot. He told Ruwet that he was "ashamed" to see his family in his present state and that he feared he might become violent with his children. Ruwet suggested he go back to see Abramson in New York, and Olson agreed. Ruwet and Olson drove back to Lashbrook's apartment on New Hampshire Avenue off Dupont Circle, and Lashbrook summoned Sid Gottlieb from Thanksgiving dinner in Virginia. All agreed that Lashbrook would take Olson back to New York while Ruwet would go back to Frederick to explain the situation to Mrs. Olson and to see his own family. (Ruwet was Olson's friend, whereas Lashbrook was no more than a professional acquaintance. Olson's son Eric believes that his father's mental state suffered when Ruwet left him in the hands of the CIA's Lashbrook, especially since Olson felt the CIA was "out to get him.") Olson and Lashbrook flew to LaGuardia airport and went to see Abramson at his Long Island office. Then the two men ate a joyless Thanksgiving dinner at a local restaurant. Friday morning Abramson drove them into Manhattan. Abramson, an allergist, finally realized that he had more on his hands with Olson than he could handle, and he recommended hospitalization. He wrote afterward that Olson "was in a psychotic state ... with delusions of persecution."

Olson agreed to enter Chestnut Lodge, a Rockville, Maryland sanitarium that had CIA-cleared psychiatrists on the staff. They could not get plane reservations until the next morning, so Olson and Lashbrook decided to spend one last night at the Statler. They took a room on the tenth floor. With his spirits revived, Olson dared to call his wife for the first time since he had left originally for New York. They had a pleasant talk, which left her feeling better.

In the early hours of the morning, Lashbrook woke up just in time to see Frank Olson crash through the drawn blinds and closed window on a dead run.

Within seconds, as a crowd gathered around Olson's shattered body on the street below, the cover-up started. Lashbrook called Gottlieb to tell him what had happened before he notified the police. Next, Lashbrook called Abramson, who, according to Lashbrook, "wanted to be kept out of the thing completely." Abramson soon called back and offered to assist. When the police arrived, Lashbrook told them he worked for the Defense Department. He said he had no idea why Olson killed himself, but he did know that the dead man had "suffered from ulcers." The detectives assigned to the case later reported that getting information out of Lashbrook was "like pulling teeth." They speculated to each other that the case could be a homicide with homosexual overtones, but they soon dropped their inquiries when Ruwet and Abramson verified Lashbrook's sketchy account and invoked high government connections.

Back in Washington, Sid Gottlieb finally felt compelled to tell the Office of Security about the Olson case. Director Allen Dulles personally ordered Inspector General Lyman Kirkpatrick to make a full investigation, but first, Agency officials tried to make sure that no outsider would tie Olson's death either to the CIA or LSD. Teams of Security officers were soon scurrying around New York and Washington, making sure the Agency had covered its tracks. One interviewed Lashbrook and then accompanied him to a meeting with Abramson. When Lashbrook and Abramson asked the security officer to leave them alone, he complied and then, in the best traditions of his office, listened in on the conversation covertly. From his report on their talk, it can safely be said that Lashbrook and Abramson conspired to make sure they told identical stories. Lashbrook dictated to Abramson, who made a recording of the symptoms that Olson was supposed to be suffering from and the problems that were bothering him. Lashbrook even stated that Mrs. Olson had suggested her husband see a psychiatrist months before the LSD incident.[7] Lashbrook's comments appeared in three reports Abramson submitted to the CIA, but these reports were internally inconsistent. In one memo, Abramson wrote that Olson's "psychotic state ... seemed to have been crystallized by [the LSD] experiment." In a later report, Abramson called the LSD dose "therapeutic" and said he believed "this dosage could hardly have had any significant role in the course of events that followed.[8]

The CIA officially - but secretly - took the position that the LSD had "triggered" Olson's suicide. Agency officials worked industriously behind the scenes to make sure that Mrs. Olson received an adequate government pension - two-thirds of her husband's base pay. Ruwet, who had threatened to expose the whole affair if Mrs. Olson did not get the pension, submitted a form saying Olson had died of a "classified illness." Gottlieb and Lashbrook kept trying to have it both ways in regard to giving Olson LSD, according to the CIA's General Counsel. They acknowledged LSD's triggering function in his death, but they also claimed it was "practically impossible" for the drug to have harmful aftereffects. The General Counsel called these two positions "completely inconsistent," and he wrote he was "not happy with what seems to me a very casual attitude on the part of TSS representatives to the way this experiment was conducted and to their remarks that this is just one of the risks running with scientific investigation."

As part of his investigation, Inspector General Kirkpatrick sequestered Gottlieb's LSD files, which Kirkpatrick remembers did not make Gottlieb at all happy. "I brought out his stutter," says Kirkpatrick with a wry smile. "He was quite concerned about his future." Kirkpatrick eventually recommended that some form of reprimand be given to Gottlieb, TSS chief Willis Gibbons, and TSS deputy chief James "Trapper" Drum, who had waited 20 days after Olson's death to admit that Gottlieb had cleared the experiment with him. Others opposed Kirkpatrick's recommendation. Admiral Luis deFlorez, the Agency's Research Chairman, sent a personal memo to Allen Dulles saying reprimands would be an "injustice" and would hinder "the spirit of initiative and enthusiasm so necessary in our work." The Director's office went along, and Kirkpatrick began the tortuous process of preparing letters for Dulles' signature that would say Gottlieb, Gibbons, and Drum had done something wrong, but nothing too wrong. Kirkpatrick went through six drafts of the Gottlieb letter alone before he came up with acceptable wording. He started out by saying TSS officials had exercised "exceedingly bad judgment." That was too harsh for high Agency officials, so Kirkpatrick tried "very poor judgment." Still too hard. He settled for "poor judgment." The TSS officials were told that they should not consider the letters to be reprimands and that no record of the letters would be put in their personnel files where they could conceivably harm future careers.

The Olson family up in Frederick did not get off so easily. Ruwet told them Olson had jumped or fallen out of the window in New York, but he mentioned not a word about the LSD, whose effects Ruwet himself believed had led to Olson's death. Ever the good soldier, Ruwet could not bring himself to talk about the classified experiment - even to ease Alice Olson's sorrow. Mrs. Olson did not want to accept the idea that her husband had willfully committed suicide. "It was very important to me - almost the core of my life - that my children not feel their father had walked out on them," recalls Mrs. Olson.

For the next 22 years, Alice Olson had no harder evidence than her own belief that her husband did not desert her and the family. Then in June 1975, the Rockefeller Commission studying illegal CIA domestic operations reported that a man fitting Frank Olson's description had leaped from a New York hotel window after the CIA had given him LSD without his knowledge. The Olson family read about the incident in the Washington Post. Daughter Lisa Olson Hayward and her husband went to see Ruwet, who had retired from the Army and settled in Frederick. In an emotional meeting, Ruwet confirmed that Olson was the man and said he could not tell the family earlier because he did not have permission. Ruwet tried to discourage them from going public or seeking compensation from the government, but the Olson family did both. [9] On national television, Alice Olson and each of her grown children took turns reading from a prepared family statement:

> We feel our family has been violated by the CIA in two ways," it said. "First, Frank Olson was experimented upon illegally and negligently. Second, the true nature of his death was concealed for twenty-two years.... In telling our story, we are concerned that neither the personal pain this family has experienced nor the moral and political outrage we feel be slighted. Only in this way can Frank Olson's death become part of American memory and serve the purpose of political and ethical reform so urgently needed in our society.

The statement went on to compare the Olsons with families in the Third World "whose hopes for a better life were destroyed by CIA intervention." Although Eric Olson read those words in behalf of the whole family, they reflected more the politics of the children than the feelings of their mother, Alice Olson. An incredibly strong woman who seems to have made her peace with the world, Mrs. Olson went back to college after her husband's death, got a degree, and held the family together while she taught school. She has no malice in her heart toward Vin Ruwet, her friend who withheld that vital piece of information from her all those years. He comforted her and gave support during the most difficult of times, and she deeply appreciates that. Mrs. Olson defends Ruwet by saying he was in "a bad position," but then she stops in mid-sentence and says, "If I had only been given some indication that it was the pressure of work.... If only I had had something I could have told the kids. I don't know how [Ruwet] could have done it either. It was a terrible thing for a man who loved him."

"I'm not vindicative toward Vin [Ruwet]," reflects Mrs. Olson. "Gottlieb is a different question. He was despicable." She tells how Gottlieb and Lashbrook both attended Olson's funeral in Frederick and contributed to a memorial fund. A week or two later, the two men asked to visit her. She knew they did not work at Detrick, but she did not really understood where they came from or their role. "I didn't want to see them," she notes. "Vin told me it would make them feel better. I didn't want an ounce of flesh from them. I didn't think it was necessary, but, okay, I agreed. In retrospect, it was so bizarre, it makes me sick ... I was a sucker for them."

Gottlieb and Lashbrook apparently never returned to the biological warfare offices at SOD. Little else changed, however. Ray Treichler and Henry Bortner took over CIA's liaison with SOD. SOD continued to manufacture and stockpile bacteriological agents for the CIA until 1969, when President Richard Nixon renounced the use of biological warfare tactics.

And presumably, someone replaced Frank Olson.

Notes 5

The description of the CIA's relationship with SOD at Fort Detrick comes from interviews with several ex-Fort Detrick employees; Church Committee hearings on "Unauthorized Storage of Toxic Agents, Volume 1; Church Committee "Summary Report on CIA Investigation of MKNAOMI" found in Report, Book I, pp. 360-63; and/ Kennedy subcommittee hearings on Biological Testing Involving Human Subjects by the Department of Defense, 1977. The details of Sid Gottlieb's involvement in the plot to kill Patrice Lumumba are found in the Church Committee's Interim Report on "Alleged Assassination Plots Involving Foreign Leaders," pp. 20-21. The Church committee allowed Gottlieb to be listed under the pseudonym Victor Scheider, but several sources confirm Gottlieb's true identity, as does the biographic data on him submitted to the Kennedy subcommittee by the CIA, which puts him in the same job attributed to "Scheider" at the same time. The plot to give botulinum to Fidel Castro is outlined in the Assassination report, pp. 79-83. The incident with the Iraqi colonel is on p. 181 of the same report.

The several inches of CIA documents on the Olson case were released by the Olson family in 1976 and can be found in the printed volume of the 1975 Kennedy subcommittee hearings on Biomedical and Behavioral

Research, pp.1005-1132. They form the base of much of the narrative, along with interviews with Alice Olson, Eric Olson, Benjamin Wilson, and several other ex-SOD men (who added next to nothing). Information also was gleaned from Vincent Ruwet's testimony before the Kennedy subcommittee in 1975, pp. 138-45 and the Church committee's summary of the affair, Book I, pp. 394-403. The quote on Harold Abramson's intention to give his patients unwitting doses of LSD is found in MKULTRA subproject 7, June 8, 1953, letter to Dr. [deleted]. Magician John Mulholland's work for the Agency is described in MKULTRA subprojects 19 and 34.

Footnotes 5

1. Toxins are chemical substances, not living organisms, derived from biological agents. While they can make people sick or dead, they cannot reproduce themselves like bacteria. Because of their biological origin, toxins came under the responsibility of Fort Detrick rather than Edgewood Arsenal, the facility which handled the chemical side of America's chemical and biological warfare (CBW) programs.
2. Brucellosis may well have been the disease that Gottlieb selected in the spring of 1960 when the Clandestine Services' Health Alteration Committee approved an operation to disable an Iraqi colonel, said to be "promoting Soviet-bloc political interests" for at least three months. Gottlieb told the Church committee that he had a monogrammed handkerchief treated with the incapacitating agency, and then mailed it to the colonel. CIA officials told the committee that the colonel was shot by a firing squad - which the Agency had nothing to do with - before the handkerchief arrived.
3. For some reason, the U.S. government has made it a point not to release information about Japanese use of biological warfare. The senior Detrick source says, "We knew they sprayed Manchuria. We had the results of how they produced and disseminated [the biological agents, including anthrax].... I read the autopsy reports myself. We had people who went over to Japan after the war."
4. Gottlieb stated just after Olson's death, at a time when he was trying to minimize his own culpability, that he had talked to the SOD men about LSD and that they had agreed in general terms to the desirability of unwitting testing. Two of the SOD group in interviews and a third in congressional testimony flatly deny the Gottlieb version. Gottlieb and the SOD men all agree Gottlieb gave no advance warning that he was giving them a drug in their liqueur.
5. For the very reason that most trips last about eight hours no matter what time a subject takes the drug, virtually all experimenters, including TSS's own contractors, give LSD in the morning to avoid the discomfort of sleepless nights.
6. To enter the SOD building, in addition to needing an incredibly hard-to-get security clearance, one had to have an up-to-date shot card with anywhere from 10 to 20 immunizations listed. The process was so painful and time consuming that at one point in the 1960s the general who headed the whole Army Chemical Corps decided against inspecting SOD and getting an on-the-spot briefing. When asked about this incident, an SOD veteran who had earlier resigned said, "That's the way we kept them out. Those [military] types didn't need to know. Most of the security violations came from the top level.... He could have gone in without shots if he had insisted. The safety director would have protested, but he could have."
7. Mrs. Olson says that this is an outright lie.
8. Nonpsychiatrist Abramson who allowed chemist Lashbrook to tell him about his patient's complexes clearly had a strange idea what was "therapeutic" - or psychotherapeutic, for that matter. In Abramson's 1953 proposal to the CIA for $85,000 to study LSD, he wrote that over the next year he "hoped" to give hospital patients "who are essentially normal from a psychiatric point of view ... unwitting doses of the drug for psychotherapeutic purposes." His treatment brings to mind the William Burroughs character in Naked Lunch who states; "Now, boys, you won't see this operation performed very often, and there's a reason for that ... you see, it has absolutely no medical value."
9. President Gerald Ford later personally apologized to the Olson family, and Congress passed a bill in 1976 to pay $750,000 in compensation to Mrs. Olson and her three children. The family voluntarily abandoned the suit.

6. Them Unwitting: The Safehouses

Frank Olson's death could have been a major setback for the Agency's LSD testing, but the program, like Sid Gottlieb's career, emerged essentially unscathed. High CIA officials did call a temporary halt to all experiments while they investigated the Olson case and re-examined the general policy. They cabled the two field stations that had supplies of the drug (Manila and Atsugi, Japan) not to use it for the time being, and they even took away Sid Gottlieb's own private supply and had it locked up in his boss' safe, to which no one else had the combination. In the end, however, Allen Dulles accepted the view Richard Helms put forth that the only "operationally realistic" way to test drugs was to try them on unwitting people. Helms noted that experiments which gave advance warning would be "pro forma at best and result in a false sense of accomplishment and readiness." For Allen Dulles and his top aides, the possible importance of LSD clearly outweighed the risks and ethical problem of slipping the drug to involuntary subjects. They gave Gottlieb back his LSD.

Once the CIA's top echelon had made its decision to continue unwitting testing, there remained, in Richard Helms' words, "only then the question of how best to do it." The Agency's role in the Olson affair had come too perilously close to leaking out for the comfort of the security-minded, so TSS officials simply had to work out a testing system with better cover. That meant finding subjects who could not be so easily traced back to the Agency.

Well before Olson's death, Gottlieb and the MKULTRA crew had started pondering how best to do unwitting testing. They considered using an American police force to test drugs on prisoners, informants, and suspects, but they knew that some local politicians would inevitably find out. In the Agency view, such people could not be trusted to keep sensitive secrets. TSS officials thought about trying Federal prisons or hospitals, but, when sounded out, the Bureau of Prisons refused to go along with true unwitting testing (as opposed to the voluntary, if coercive, form practiced on drug addicts in Kentucky). They contemplated moving the program overseas, where they and the ARTICHOKE teams were already performing operational experiments, but they decided if they tested on the scale they thought was necessary, so many foreigners would have to know that it would pose an unacceptable security risk.

Sid Gottlieb is remembered as the brainstorming genius of the MKULTRA group - and the one with a real talent for showing others, without hurting their feelings, why their schemes would not work. States an ex-colleague who admires him greatly, "In the final analysis, Sid was like a good soldier - if the job had to be done, he did it. Once the decision was made, he found the most effective way."

In this case, Gottlieb came up with the solution after reading through old OSS files on Stanley Lovell's search for a truth drug. Gottlieb noted that Lovell had used George White, a prewar employee of the Federal Bureau of Narcotics, to test concentrated marijuana. Besides trying the drug out on Manhattan Project volunteers and unknowing suspected Communists, White had slipped some to August Del Gracio, the Lucky Luciano lieutenant. White had called the experiment a great success. If it had not been - if Del Gracio had somehow caught on to the drugging - Gottlieb realized that the gangster would never have gone to the police or the press. His survival as a criminal required he remain quiet about even the worst indignities heaped upon him by government agents.

To Gottlieb, underworld types looked like ideal test subjects. Nevertheless, according to one TSS source, "We were not about to fool around with the Mafia." Instead, this source says they chose "the borderline underworld" - prostitutes, drug addicts, and other small-timers who would be powerless to seek any sort of revenge if they ever found out what the CIA had done to them. In addition to their being unlikely whistle-blowers, such people lived in a world where an unwitting dose of some drug - usually knockout drops - was an occupational hazard anyway. They would therefore be better equipped to deal with - and recover from - a surprise LSD trip than the population as a whole. Or so TSS officials rationalized. "They could at least say to themselves, 'Here I go again. I've been slipped a mickey,"' says a TSS veteran. Furthermore, this veteran remembers, his former colleagues reasoned that if they had to violate the civil rights of anyone, they might as well choose a group of marginal people.

George White himself had left OSS after the war and returned to the Narcotics Bureau. In 1952 he was working in the New York office. As a high-ranking narcotics agent, White had a perfect excuse to be around drugs and people who used them. He had proved during the war that he had a talent for clandestine work, and he certainly had no qualms when it came to unwitting testing. With his job, he had access to all the possible subjects the Agency would need, and if he could use LSD or any other drug to find out more about drug trafficking, so much the better. From a security viewpoint, CIA officials could easily deny any connection to anything White did, and he clearly was not the crybaby type. For Sid Gottlieb, George White was clearly the one. The MKULTRA chief decided to contact White directly to see if he might be interested in picking up with the CIA where he had left off with OSS.

Always careful to observe bureaucratic protocol, Gottlieb first approached Harry Anslinger, the longtime head of the Federal Bureau of Narcotics, and got permission to use White on a part-time basis. Then Gottlieb traveled to New York and made his pitch to the narcotics agent, who stood 5'7", weighed over 200 pounds, shaved his head, and looked something like an extremely menacing bowling ball. After an early-morning meeting, White scrawled in his sweat-stained, leather-bound diary for that day, June 9, 1952: "Gottlieb proposed I be a CIA consultant - I agree." By writing down such a thing and using Gottlieb's true name,[1] White had broken CIA security regulations even before he started work. But then, White was never known as a man who followed rules.

Despite the high priority that TSS put on drug testing, White's security approval did not come through until almost a year later. "It was only last month that I got cleared," the outspoken narcotics agent wrote to a friend in 1953. "I then learned that a couple of crew-cut, pipe-smoking punks had either known me - or heard of me - during OSS days and had decided I was 'too rough' for their league and promptly blackballed me. It was only when my sponsors discovered the root of the trouble they were able to bypass the blockade. After all, fellas, I didn't go to Princeton."

People either loved or hated George White, and he had made some powerful enemies, including New York Governor Thomas Dewey and J. Edgar Hoover. Dewey would later help block White from becoming the head of the Narcotics Bureau in New York City, a job White sorely wanted. For some forgotten reason, Hoover had managed to stop White from being hired by the CIA in the Agency's early days, at a time when he would have preferred to leave narcotics work altogether. These were two of the biggest disappointments of his life. White's previous exclusion from the CIA may explain why he jumped so eagerly at Gottlieb's offer and why at the same time he privately heaped contempt on those who worked for the Agency. A remarkably heavy drinker, who would sometimes finish off a bottle of gin in one sitting, White often mocked the CIA crowd over cocktails. "He thought they were a joke," recalls one longtime crony. "They were too complicated, and they had other people do their heavy stuff."

Unlike his CIA counterparts, White loved the glare of publicity. A man who gloried in talking about himself and cultivating a hard-nosed image, White knew how to milk a drug bust for all it was worth - a skill that grew out of early years spent as a newspaper reporter in San Francisco and Los Angeles. In search of a more financially secure profession, he had joined the Narcotics Bureau in 1934, but he continued to pal around with journalists, particularly those who wrote favorably about him. Not only did he come across in the press as a cop hero, but he helped to shape the picture of future Kojaks by serving as a consultant to one of the early-television detective series. To start a raid, he would dramatically tip his hat to signal his agents - and to let the photographers know that the time had come to snap his picture. "He was sort of vainglorious," says another good friend, "the kind of guy who if he did something, didn't mind having the world know about it."[2]

The scientists from TSS, with their Ph.D.s and lack of street experience, could not help admiring White for his swashbuckling image. Unlike the men from MKULTRA, who, for all their pretensions, had never worked as real-live spies, White had put his life on the line for OSS overseas and had supposedly killed a Japanese agent with his bare hands. The face of one ex-TSS man lit up, like a little boy's on Christmas morning, as he told of racing around New York in George White's car and parking illegally with no fear of the law. "We were Ivy League, white, middle-class," notes another former TSSer. "We were naive, totally naive about this, and he felt pretty expert. He knew the whores, the pimps, the people who brought in the drugs. He'd purportedly been in a number of shootouts where he'd captured millions of dollars worth of heroin.... He was a pretty wild man. I know I was afraid of him. You couldn't control this guy ... I had a little trouble telling who was controlling who in those days."

White lived with extreme personal contradictions. As could be expected of a narcotics agent, he violently opposed drugs. Yet he died largely because his beloved alcohol had destroyed his liver. He had tried everything else, from marijuana to LSD, and wrote an acquaintance, "I did feel at times I was having a 'mind-expanding' experience but this vanished like a dream immediately after the session." He was a law-enforcement official who regularly violated the law. Indeed, the CIA turned to him because of his willingness to use the power of his office to ride roughshod over the rights of others - in the name of "national security," when he tested LSD for the Agency, in the name of stamping out drug abuse, for the Narcotics Bureau. As yet another close associate summed up White's attitude toward his job, "He really believed the ends justified the means."

George White's "pragmatic" approach meshed perfectly with Sid Gottlieb's needs for drug testing. In May 1953 the two men, who wound up going folk dancing together several times, formally joined forces. In CIA jargon, White became MKULTRA subproject #3. Under this arrangement, White rented two adjacent Greenwich Village apartments, posing as the sometime artist and seaman "Morgan Hall." White agreed to lure guinea pigs to the "safehouse" - as the Agency men called the apartments - slip them drugs, and report the results to Gottlieb and the others in TSS. For its part, the CIA let the Narcotics Bureau use the place for undercover activities (and often for personal pleasure) whenever no Agency work was scheduled, and the CIA paid all the bills, including the cost of keeping a well-stocked liquor cabinet - a substantial bonus for White. Gottlieb personally handed over the first $4,000 in cash, to cover the initial costs of furnishing the safehouse in the lavish style that White felt befitted him.

Gottlieb did not limit his interest to drugs. He and other TSS officials wanted to try out surveillance equipment. CIA technicians quickly installed see-through mirrors and microphones through which eavesdroppers could film, photograph, and record the action. "Things go wrong with listening devices and two-way mirrors, so you build these things to find out what works and what doesn't," says a TSS source. "If you are going to entrap, you've got to give the guy pictures [flagrante delicto] and voice recordings. Once you learn how to do it so that the whole thing looks comfortable, cozy, and safe, then you can transport the technology overseas and use it." This TSS man notes that the Agency put to work in the bedrooms of Europe some of the techniques developed in the George White safehouse operation.

In the safehouse's first months, White tested LSD, several kinds of knockout drops, and that old OSS standby, essence of marijuana. He served up the drugs in food, drink, and cigarettes and then tried to worm information - usually on narcotics matters - from his "guests." Sometimes MKULTRA men came up from Washington to watch the action. A September 1953 entry in White's diary noted: "Lashbrook at 81 Bedford Street - Owen Winkle and LSD surprise - can wash." Sid Gottlieb's deputy, Robert Lashbrook, served as "project monitor" for the New York safehouse.[3]

White had only been running the safehouse six months when Olson died (in Lashbrook's company), and Agency officials suspended the operation for reevaluation. They soon allowed him to restart it, and then Gottlieb had to order White to slow down again. A New York State commissioner had summoned the narcotics agent to explain his role in the deal that wound up with Governor Dewey pardoning Lucky Luciano after the war. The commissioner was asking questions that touched on White's use of marijuana on Del Gracio, and Gottlieb feared that word of the CIA's current testing might somehow leak out. This storm also soon passed, but then, in early 1955, the Narcotics Bureau transferred White to San Francisco to become chief agent there. Happy with White's performance, Gottlieb decided to let him take the entire safehouse operation with him to the Coast. White closed up the Greenwich Village apartments, leaving behind unreceipted "tips" for the landlord "to clear up any difficulties about the alterations and damages," as a CIA document put it.[4]

White soon rented a suitable "pad" (as he always called it) on Telegraph Hill, with a stunning view of San Francisco Bay, the Golden Gate Bridge, and Alcatraz. To supplement the furniture he brought from the New York safehouse, he went out and bought items that gave the place the air of the brothel it was to become: Toulouse-Lautrec posters, a picture of a French cancan dancer, and photos of manacled women in black stockings. "It was supposed to look rich," recalls a narcotics agent who regularly visited, "but it was furnished like crap."

White hired a friend's company to install bugging equipment, and William Hawkins, a 25-year-old electronics whiz then studying at Berkley put in four DD-4 microphones disguised as electrical wall outlets and hooked them up to two F-301 tape recorders, which agents monitored in an adjacent "listening post." Hawkins remembers that White "kept a pitcher of martinis in the refrigerator, and he'd watch me for a while as I installed a microphone and then slip off." For his own personal "observation post," White had a portable toilet set up behind a two-way mirror, where he could watch the proceedings, usually with drink in hand.

The San Francisco safehouse specialized in prostitutes. "But this was before The Hite Report and before any hooker had written a book," recalls a TSS man, "so first we had to go out and learn about their world. In the beginning, we didn't know what a john was or what a pimp did." Sid Gottlieb decided to send his top staff psychologist, John Gittinger, to San Francisco to probe the demimonde.

George White supplied the prostitutes for the study, although White, in turn, delegated much of the pimping function to one of his assistants, Ira "Ike" Feldman. A muscular but very short man, whom even the 5'7" White towered over, Feldman tried even harder than his boss to act tough. Dressed in suede shoes, a suit with flared trousers, a hat with a turned-up brim, and a huge zircon ring that was supposed to look like a diamond, Feldman first came to San Francisco on an undercover assignment posing as an East Coast mobster looking to make a big heroin buy. Using a drug-addicted prostitute name Janet Jones, whose common-law husband states that Feldman paid her off with heroin, the undercover man lured a number of suspected drug dealers to the "pad" and helped White make arrests.

As the chief Federal narcotics agent in San Francisco, White was in a position to reward or punish a prostitute. He set up a system whereby he and Feldman provided Gittinger with all the hookers the psychologist wanted. White paid off the women with a fixed number of "chits." For each chit, White owed one favor. "So the next time the girl was arrested with a john," says an MKULTRA veteran, "she would give the cop George White's phone number. The police all knew White and cooperated with him without asking questions. They would release the girl if he said so. White would keep good records of how many chits each person had and how many she used. No money was exchanged, but five chits were worth $500 to $1,000." Prostitutes were not the only beneficiaries of White's largess. The narcotics agent worked out a similar system to forgive the transgressions of small time drug pushers when the MKULTRA men wanted to talk to them about "the rules of their game," according to the source.

TSS officials wanted to find out everything they could about how to apply sex to spying, and the prostitute project became a general learning and then training ground for CIA carnal operations. After all, states one TSS official, "We did quite a study of prostitutes and their behavior.... At first nobody really knew how to use them. How do you train them? How do you work them? How do you take a woman who is willing to use her body to get money out of a guy to get things which are much more important, like state secrets. I don't care how beautiful she is - educating the ordinary prostitute up to that level is not a simple task."

The TSS men continually tried to refine their knowledge. They realized that prostitutes often wheedled extra money out of a customer by suggesting some additional service as male orgasm neared. They wondered if this might not also be a good time to seek sensitive information. "But no," says the source, "we found the guy was focused solely on hormonal needs. He was not thinking of his career or anything else at that point." The TSS experts discovered that the postsexual, light-up-acigarette period was much better suited to their ulterior motives. Says the source:

> Most men who go to prostitutes are prepared for the fact that [after the act] she's beginning to work to get herself out of there, so she can get back on the street to make some more money... . To find a prostitute who is willing to stay is a hell of a shock to anyone used to prostitutes. It has a tremendous effect on the guy. It's a boost to his ego if she's telling him he was really neat, and she wants to stay for a few more hours.... Most of the time, he gets pretty vulnerable. What the hell's he going to talk about? Not the sex, so he starts talking about his business. It's at this time she can lead him gently. But you have to train prostitutes to do that. Their natural inclination is to do exactly the opposite.

The men from MKULTRA learned a great deal about varying sexual preferences. One of them says:

> We didn't know in those days about hidden sadism and all that sort of stuff. We learned a lot about human nature in the bedroom. We began to understand that when people wanted sex, it wasn't just what we had thought of - you know, the missionary position.... We started to pick up

> knowledge that could be used in operations, but with a lot of it we never figured out any way to use it operationally. We just learned.... All these ideas did not come to us at once. But evolving over three or four years in which these studies were going on, things emerged which we tried. Our knowledge of prostitutes' behavior became pretty damn good... . This comes across now that somehow we were just playing around and we just found all these exotic ways to waste the taxpayers' money on satisfying our hidden urges. I'm not saying that watching prostitutes was not exciting or something like that. But what I am saying was there was a purpose to the whole business.[5]

In the best tradition of Mata Hari, the CIA did use sex as a clandestine weapon, although apparently not so frequently as the Russians. While many in the Agency believed that it simply did not work very well, others like CIA operators in Berlin during the mid-1960s felt prostitutes could be a prime source of intelligence. Agency men in that city used a network of hookers to good advantage - or so they told visitors from headquarters. Yet, with its high proportion of Catholics and Mormons - not to mention the Protestant ethic of many of its top leaders - the Agency definitely had limits beyond which prudery took over. For instance, a TSS veteran says that a good number of case officers wanted no part of homosexual entrapment operations. And to go a step further, he recalls one senior KGB man who told too many sexual jokes about young boys. "It didn't take too long to recognize that he was more than a little fascinated by youths," says the source. "I took the trouble to point out he was probably too good, too well-trained, to be either entrapped or to give away secrets. But he would have been tempted toward a compromising position by a preteen. I mentioned this, and they said, 'As a psychological observer, you're probably quite right. But what the hell are we going to do about it? Where are we going to get a twelve-year-old boy?' " The source believes that if the Russian had had a taste for older men, U.S. intelligence might have mounted an operation, "but the idea of a twelve-year-old boy was just more than anybody could stomach."

As the TSS men learned more about the San Francisco hustlers, they ventured outside the safehouse to try out various clandestine-delivery gimmicks in public places like restaurants, bars, and beaches. They practiced ways to slip LSD to citizens of the demimonde while buying them a drink or lighting up a cigarette, and they then tried to observe the effects when the drug took hold. Because the MKULTRA scientists did not move smoothly among the very kinds of people they were testing, they occasionally lost an unwitting victim in a crowd - thereby sending a stranger off alone with a head full of LSD.

In a larger sense, all the test victims would become lost. As a matter of policy, Sid Gottlieb ordered that virtually no records be kept of the testing. In 1973, when Gottlieb retired from the Agency, he and Richard Helms agreed to destroy what they thought were the few existing documents on the program. Neither Gottlieb nor any other MKULTRA man has owned up to having given LSD to an unknowing subject, or even to observing such an experiment - except of course in the case of Frank Olson. Olson's death left behind a paper trail outside of Gottlieb's control and that hence could not be denied. Otherwise, Gottlieb and his colleagues have put all the blame for actual testing on George White, who is not alive to defend himself. One reason the MKULTRA veterans have gone to such lengths to conceal their role is obvious: fear of lawsuits from victims claiming damaged health.

At the time of the experiments, the subjects' health did not cause undue concern. At the safehouse, where most of the testing took place, doctors were seldom present. Dr. James Hamilton, a Stanford Medical School psychiatrist and White's OSS colleague, visited the place from time to time, apparently for studies connected to unwitting drug experiments and deviant sexual practices. Yet neither Hamilton nor any other doctor provided much medical supervision. From his perch atop the toilet seat, George White could do no more than make surface observations of his drugged victims. Even an experienced doctor would have had difficulty handling White's role. In addition to LSD, which they knew could cause serious, if not fatal problems, TSS officials gave White even more exotic experimental drugs to test, drugs that other Agency contractors may or may not have already used on human subjects. "If we were scared enough of a drug not to try it out on ourselves, we sent it to San Francisco," recalls a TSS source. According to a 1963 report by CIA Inspector General John Earman, "In a number of instances, however, the test subject has become ill for hours or days, including hospitalization in at least one case, and [White] could only follow up by guarded inquiry after the test subject's return to normal life. Possible sickness and attendant economic loss are inherent contingent effects of the testing."

The Inspector General noted that the whole program could be compromised if an outside doctor made a "correct diagnosis of an illness." Thus, the MKULTRA team not only made some people sick but had a vested interest in keeping doctors from finding out what was really wrong. If that bothered the Inspector General, he did not report his qualms, but he did say he feared "serious damage to the Agency" in the event of public exposure. The Inspector General was only somewhat reassured by the fact that George White "maintain[ed] close working relations with local police authorities which could be utilized to protect the activity in critical situations."

If TSS officials had been willing to stick with their original target group of marginal underworld types, they would have had little to fear from the police. After all, George White was the police. But increasingly they used the safehouse to test drugs, in the Inspector General's words, "on individuals of all social levels, high and low, native American and foreign." After all, they were looking for an operational payoff, and they knew people reacted differently to LSD according to everything from health and mood to personality structure. If TSS officials wanted to slip LSD to foreign leaders, as they contemplated doing to Fidel Castro, they would try to spring an unwitting dose on somebody as similar as possible. They used the safehouse for "dry runs" in the intermediate stage between the laboratory and actual operations.

For these dress rehearsals, George White and his staff procurer, Ike Feldman, enticed men to the apartment with prostitutes. An unsuspecting john would think he had bought a night of pleasure, go back to a strange apartment, and wind up zonked. A CIA document that survived Sid Gottlieb's shredding recorded this process. Its author, Gottlieb himself, could not break a lifelong habit of using nondescriptive language. For the MKULTRA chief, the whores were "certain individuals who covertly administer this material to other people in accordance with [White's] instructions." White normally paid the women $100 in Agency funds for their night's work, and Gottlieb's prose reached new bureaucratic heights as he explained why the prostitutes did not sign for the money: "Due to the highly unorthodox nature of these activities and the considerable risk incurred by these individuals, it is impossible to require that they provide a receipt for these payments or that they indicate the precise manner in which the funds were spent." The CIA's auditors had to settle for canceled checks which White cashed himself and marked either "Stormy" or, just as appropriately, "Undercover Agent." The program was also referred to as "Operation Midnight Climax."

TSS officials found the San Francisco safehouse so successful that they opened a branch office, also under George White's auspices, across the Golden Gate on the beach in Marin County.[6] Unlike the downtown apartment, where an MKULTRA man says "you could bring people in for quickies after lunch," the suburban Marin County outlet proved useful for experiments that required relative isolation. There, TSS scientists tested such MKULTRA specialties as stink bombs, itching and sneezing powders, and diarrhea inducers. TSS's Ray Treichler, the Stanford chemist, sent these "harassment substances" out to California for testing by White, along with such delivery systems as a mechanical launcher that could throw a foul-smelling object 100 yards, glass ampules that could be stepped on in a crowd to release any of Treichler's powders, a fine hypodermic needle to inject drugs through the cork in a wine bottle, and a drug-coated swizzle stick.

TSS men also planned to use the Marin County safehouse for an ill-fated experiment that began when staff psychologists David Rhodes and Walter Pasternak spent a week circulating in bars, inviting strangers to a party. They wanted to spray LSD from an aerosol can on their guests, but according to Rhodes' Senate testimony, "the weather defeated us." In the heat of the summer, they could not close the doors and windows long enough for the LSD to hang in the air and be inhaled. Sensing a botched operation, their MKULTRA colleague, John Gittinger (who brought the drug out from Washington) shut himself in the bathroom and let go with the spray. Still, Rhodes testified, Gittinger did not get high, and the CIA men apparently scrubbed the party.[7]

The MKULTRA crew continued unwitting testing until the summer of 1963 when the Agency's Inspector General stumbled across the safehouses during a regular inspection of TSS activities. This happened not long after Director John McCone had appointed John Earman to the Inspector General position.[8] Much to the displeasure of Sid Gottlieb and Richard Helms, Earman questioned the propriety of the safehouses, and he insisted that Director McCone be given a full briefing. Although President Kennedy had put McCone in charge of the Agency the year before, Helms - the professional's professional - had not bothered to tell his outsider boss about some of the CIA's most sensitive activities, including the safehouses and the CIA-Mafia assassination plots.[9] Faced with Earman's demands, Helms - surely one of history's most clever bureaucrats -

volunteered to tell McCone himself about the safehouses (rather than have Earman present a negative view of the program). Sure enough, Helms told Earman afterward, McCone raised no objections to unwitting testing (as Helms described it). A determined man and a rather brave one, Earman countered with a full written report to McCone recommending that the safehouses be closed. The Inspector General cited the risks of exposure and pointed out that many people both inside and outside the Agency found "the concepts involved in manipulating human behavior ... to be distasteful and unethical." McCone reacted by putting off a final decision but suspending unwitting testing in the meantime. Over the next year, Helms, who then headed the Clandestine Services, wrote at least three memos urging resumption. He cited "indications ... of an apparent Soviet aggressiveness in the field of covertly administered chemicals which are, to say the least, inexplicable and disturbing," and he claimed the CIA's "positive operational capacity to use drugs is diminishing owing to a lack of realistic testing."[10] To Richard Helms, the importance of the program exceeded the risks and the ethical questions, although he did admit, "We have no answer to the moral issue." McCone simply did nothing for two years. The director's indecision had the effect of killing the program, nevertheless. TSS officials closed the San Francisco safehouse in 1965 and the New York one in 1966.

Years later in a personal letter to Sid Gottlieb, George White wrote an epitaph for his role with the CIA: "I was a very minor missionary, actually a heretic, but I toiled wholeheartedly in the vineyards because it was fun, fun, fun. Where else could a red-blooded American boy lie, kill, cheat, steak rape, and pillage with the sanction and blessing of the All-Highest?"

After 10 years of unwitting testing, the men from MKULTRA apparently scored no major breakthroughs with LSD or other drugs. They found no effective truth drug, recruitment pill, or aphrodisiac. LSD had not opened up the mind to CIA control. "We had thought at first that this was the secret that was going to unlock the universe," says a TSS veteran. "We found that human beings had resources far greater than imagined."

Yet despite the lack of precision and uncertainty, the CIA still made field use of LSD and other drugs that had worked their way through the MKULTRA testing progression. A 1957 report showed that TSS had already moved 6 drugs out of the experimental stage and into active use. Up to that time, CIA operators had utilized LSD and other psychochemicals against 33 targets in 6 different operations. Agency officials hoped in these cases either to discredit the subject by making him seem insane or to "create within the individual a mental and emotional situation which will release him from the restraint of self-control and induce him to reveal information willingly under adroit manipulation." The Agency has consistently refused to release details of these operations, and TSS sources who talk rather freely about other matters seem to develop amnesia when the subject of field use comes up. Nevertheless, it can be said that the CIA did establish a relationship with an unnamed foreign secret service to interrogate prisoners with LSD-like drugs. CIA operators participated directly in these interrogations, which continued at least until 1966. Often the Agency showed more concern for the safety of its operational targets abroad than it did for its unwitting victims in San Francisco, since some of the foreign subjects were given medical examinations before being slipped the drug.[11]

In these operations, CIA men sometimes brought in local doctors for reasons that had nothing to do with the welfare of the patient. Instead, the doctor's role was to certify the apparent insanity of a victim who had been unwittingly dosed with LSD or an even more durable psychochemical like BZ (which causes trips lasting a week or more and which tends to induce violent behavior). If a doctor were to prescribe hospitalization or other severe treatment, the effect on the subject could be devastating. He would suffer not only the experience itself, including possible confinement in a mental institution, but also social stigma. In most countries, even the suggestion of mental problems severely damages an individual's professional and personal standing (as Thomas Eagleton, the recipient of some shock therapy, can testify). "It's an old technique," says an MKULTRA veteran. "You neutralize someone by having their constituency doubt them." The Church committee confirms that the Agency used this technique at least several times to assassinate a target's character.[12]

Still, the Clandestine Services did not frequently call on TSS for LSD or other drugs. Many operators had practical and ethical objections. In part to overcome such objections and also to find better ways to use chemical and biological substances in covert operations, Sid Gottlieb moved up in 1959 to become Assistant for Scientific Matters to the Clandestine Services chief. Gottlieb found that TSS had kept the MKULTRA programs so secret that many field people did not even know what techniques were available. He wrote that tight controls over field use in MKDELTA operations "may have generated a general defeatism among case officers," who feared they would not receive permission or that the procedure was not worth the effort.

Gottlieb tried to correct these shortcomings by providing more information on the drug arsenal to senior operators and by streamlining the approval process. He had less luck in overcoming views that drugs do not work or are not reliable, and that their operational use leads to laziness and poor tradecraft.

If the MKULTRA program had ever found that LSD or any other drug really did turn a man into a puppet, Sid Gottlieb would have had no trouble surmounting all those biases. Instead, Gottlieb and his fellow searchers came frustratingly close but always fell short of finding a reliable control mechanism. LSD certainly penetrated to the innermost regions of the mind. It could spring loose a whole gamut of feelings, from terror to insight. But in the end, the human psyche proved so complex that even the most skilled manipulator could not anticipate all the variables. He could use LSD and other drugs to chip away at free will. He could score temporary victories, and he could alter moods, perception - sometimes even beliefs. He had the power to cause great harm, but ultimately he could not conquer the human spirit.

Notes 6

The CIA's reaction to Frank Olson's death is described in numerous memos released by the Agency to the Olson family, which can be found at pp.1005-1132 of the Kennedy Subcommittee 1975 hearings on Biomedical and Behavioral Research. See particularly at p. 1077, 18 December 1953, Subject: The Suicide of Frank Olson and at p. 1027, 1 December 1953, Subject: Use of LSD.

Richard Helms' views on unwitting testing are found in Document #448, 17 December 1963, Subject: Testing of Psychochemicals and Related Materials and in a memorandum to the CIA Director, June 9, 1964, quoted from on page 402 of the Church Committee Report, Book I.

George White's diary and letters were donated by his widow to Foothills Junior College, Los Altos, California and are the source of a treasure chest of material on him, including his letter to a friend explaining his almost being "blackballed" from the CIA, the various diary entries cited, including references to folk-dancing with Gottlieb, the interview with Hal Lipset where he explains his philosophy on chasing criminals, and his letter to Sid Gottlieb dated November 21, (probably) 1972.

The New York and San Francisco safehouses run by George White are the subjects of MKULTRA subprojects 3,14,16,42, and 149. White's tips to the landlord are described in 42-156, his liquor bills in 42-157, "dry-runs" in 42-91. The New York safehouse run by Charles Siragusa is subproject 132. The "intermediate" tests are described in document 132-59.

Paul Avery, a San Francisco freelance writer associated with the Center for Investigative Reporting in Oakland, California interviewed William Hawkins and provided assistance on the details of the San Francisco safehouse and George White's background. Additional information on White came from interviews with his widow, several former colleagues in the Narcotics Bureau, and other knowledgeable sources in various San Francisco law-enforcement agencies. An ex-Narcotics Bureau official told of Dr. James Hamilton's study of unusual sexual practices and the description of his unwitting drug testing comes from MKULTRA subproject 2, which is his subproject.

Ray Treichler discussed some of his work with harassment substances in testimony before the Kennedy subcommittee on September 20, 1977, pp. 105-8. He delivered his testimony under the pseudonym "Philip Goldman."

"The Gang that Couldn't Spray Straight" article appeared in the September 20, 1977 Washington Post.

Richard Helms' decision not to tell John McCone about the CIA's connection to the Mafia in assassination attempts against Castro is described in the Church Committee's Assassination report, pp. 102-3.

The 1957 Inspector General's Report on TSS, Document #417 and the 1963 inspection of MKULTRA, 14 August 1963, Document #59 provided considerable detail throughout the entire chapter. The Church Committee Report on MKULTRA in Book I, pp. 385-422 also provided considerable information.

Sid Gottlieb's job as Assistant to the Clandestine Services chief for Scientific Matters is described in Document

#74 (operational series) 20 October 1959, Subject: Application of Imaginative Research on the Behavioral and Physical Sciences to [deleted] Problems" and in the 1963 Inspector General's report.

Interviews with ex-CIA Inspector General Lyman Kirkpatrick, another former Inspector General's staff employee, and several ex-TSS staffers contributed significantly to this chapter.

Helms' letter to the Warren Commission on "Soviet Brainwashing Techniques," dated 19 June 1964, was obtained from the National Archives.

The material on the CIA's operational use of LSD came from the Church Committee Report, Book I, pp. 399-403 and from an affidavit filed in the Federal Court case of John D. Marks v. Central Intelligence Agency, et. al., Civil Action No. 76-2073 by Eloise R. Page, Chief, Policy and Coordination Staff of the CIA's Directorate of Operations. In listing all the reasons why the Agency should not provide the operational documents, Ms. Page gave some information on what was in the documents. The passages on TSS's and the Medical Office's positions on the use of LSD came from a memo written by James Angleton, Chief, Counterintelligence Staff on December 12, 1957 quoted in part at p. 401 of the Church Committee Report, Book I.

Footnotes 6

1. CIA operators and agents all had cover names by which they were supposed to be called - even in classified documents. Gottlieb was "Sherman R. Grifford." George White became "Morgan Hall."
2. One case which put White in every newspaper in the country was his 1949 arrest of blues singer Billie Holliday on an opium charge. To prove she had been set up and was not then using drugs, the singer checked into a California sanitarium that had been recommended by a friend of a friend, Dr. James Hamilton. The jury then acquitted her. Hamilton's involvement is bizarre because he had worked with George White testing truth drugs for OSS, and the two men were good friends. White may have put his own role in perspective when he told a 1970 interviewer he "enjoyed" chasing criminals. "It was a game for me," he said. "I felt quite a bit of compassion for a number of the people that I found it necessary to put in jail, particularly when you'd see the things that would happen to their families. I'd give them a chance to stay out of jail and take care of their families by giving me information, perhaps, and they would stubbornly refuse to do so. They wouldn't be a rat, as they would put it."
3. Despite this indication from White's diary that Lashbrook came to the New York safehouse for an "LSD surprise" and despite his signature on papers authorizing the subproject, Lashbrook flatly denied all firsthand knowledge of George White's testing in 1977 Senate testimony. Subcommittee chairman Edward Kennedy did not press Lashbrook, nor did he refer the matter to the Justice Department for possible perjury charges.
4. This was just one of many expenditures that would drive CIA auditors wild while going over George White's accounts. Others included $44.04 for a telescope, liquor bills over $1,000 "with no record as to the necessity of its use," and $31.75 to make an on-the-spot payment to a neighborhood lady whose car he hit. The reason stated for using government funds for the last expense: "It was important to maintain security and forestall an insurance investigation."
5. In 1984, George Orwell wrote about government-encouraged prostitution: "Mere debauchery did not matter very much, so long as it was furtive and joyless, and only involved the women of a submerged and despised class."
6. In 1961 MKULTRA officials started a third safehouse in New York, also under the Narcotics Bureau's supervision. This one was handled by Charles Siragusa who, like White, was a senior agent and OSS veteran.
7. Rhodes' testimony about this incident, which had been set up in advance with Senator Edward Kennedy's staff, brought on the inevitable "Gang That Couldn't Spray Straight" headline in the Washington Post. This approach turned the public perception of a deadly serious program into a kind of practical joke carried out badly by a bunch of bumblers.
8. Lyman Kirkpatrick, the longtime Inspector General who had then recently left the job to take a higher Agency post, had personally known of the safehouse operation since right after Olson's death and had never raised any noticeable objection. He now states he was "shocked" by the unwitting testing, but that he "didn't have the authority to follow up ... I was trying to determine what the tolerable limits were of what I could do and still keep my job."
9. Trying to explain why he had specifically decided not to inform the CIA Director about the Agency's relationship with the mob, Helms stated to the Church committee, "Mr. McCone was relatively new to this organization, and I guess I must have thought to myself, well this is going to look peculiar to him ... This was, you know not a very savory effort." Presumably, Helms had similar reasons for not telling McCone about the unwitting drug-testing in the safehouses.
10. Helms was a master of telling different people different stories to suit his purposes. At the precise time he was raising the Soviet menace to push McCone into letting the unwitting testing continue, he wrote the Warren Commission that not only did Soviet behavioral research lag five years behind the West's but that "there is no present evidence that the Soviets have any singular, new potent, drugs ... to force a course of action on an individual."
11. TSS officials led by Sid Gottlieb, who were responsible for the operational use of LSD abroad, took the position that there was "no danger medically" in unwitting doses and that neither giving a medical exam or having a doctor present was necessary. The Agency's Medical Office disagreed, saying the drug was "medically dangerous." In 1957 Inspector General Lyman Kirkpatrick noted it would be "unrealistic" to give the Medical Office what amounted to veto power over covert operations by letting Agency doctors rule on the health hazard to subjects in the field.
12. While I was doing the research for this book, many people approached me claiming to be victims of CIA drugging plots. Although I listened carefully to all and realized that some might be authentic victims, I had no way of distinguishing between someone acting strangely and someone made to act strangely. Perhaps the most insidious aspect of this whole technique is

that anyone blaming his aberrant behavior on a drug or on the CIA gets labeled a hopeless paranoid and his case is thrown into the crank file. There is no better cover than operating on the edge of madness.

One leftist professor in a Latin American university who had opposed the CIA says that he was working alone in his office one day in 1974 when a strange woman entered and jabbed his wrist with a pin stuck in a small round object. Almost immediately, he become irrational, broke glasses, and threw water in colleagues' faces. He says his students spotted an ambulance waiting for him out front. They spirited him out the back door and took him home, where he tripped (or had psychotic episodes) for more than a week. He calls the experience a mix of "heaven and hell," and he shudders at the thought that he might have spent the time in a hospital "with nurses and straitjackets." Although he eventually returned to his post at the university, he states that it took him several years to recover the credibility he lost the day he "went crazy at the office." If the CIA was involved, it had neutralized a foe.

7. Mushrooms to Counterculture

The MKULTRA scientists reaped little but disaster, mischief, and disappointment from their efforts to use LSD as a miracle weapon against the minds of their opponents. Nevertheless, their insatiable need to try every possibility led them to test hundreds of other substances, including all the drugs that would later be called psychedelic. These drugs were known to have great potency. They were derived from natural botanical products, and the men from MKULTRA believed from the beginning that rare organic materials might somehow have the greatest effect on the human mind. The most amazing of the psychedelics came from odd corners of the natural world. A1bert Hofmann created LSD largely out of ergot, a fungus that grows on rye; mescaline is nothing more than the synthetic essence of peyote cactus. Psilocybin, the drug that Timothy Leary preferred to LSD for his Harvard experiments, was synthesized from exotic Mexican mushrooms that occupy a special place in CIA history.

When the MKULTRA team first embarked on its mind-control explorations, the "magic mushroom" was only a rumor or fable in the linear history of the Western world. On nothing more than the possibility that the legend was based on fact, the Agency's scientists tracked the mushroom to the most remote parts of Mexico and then spent lavishly to test and develop its mind-altering properties. The results, like the LSD legacy, were as startling as they were unintended.

Among the botanicals that mankind has always turned to for intoxicants and poisons, mushrooms stand out. There is something enchantingly odd about the damp little buttons that can thrill a gourmet or kill one, depending on the subtle differences among the countless varieties. These fungi have a long record in unorthodox warfare. Two thousand years before the CIA looked to unleash powerful mushrooms in covert operations, the Roman Empress Agrippina eliminated her husband Claudius with a dish of poisonous mushrooms. According to Roman history, Agrippina wanted the emperor dead so that her son Nero could take the throne. She planned to take advantage of Claudius' love for the delicious *Amanita caesarea* mushroom, but she had to choose carefully among its deadly look-alikes. The poison could not be "sudden and instantaneous in its operation, lest the desperate achievement should be discovered," wrote Gordon and Valentina Wasson in their monumental and definitive work, Mushrooms, Russia and History. The Empress settled on the lethal *Amanita phalloides*, a fungus the Wassons considered well suited to the crime: "The victim would not give away the game by abnormal indispositions at the meal, but when the seizure came he would be so severely stricken that thereafter he would no longer be in command of his own affairs." Agrippina knew her mushrooms, and Nero became Emperor.

CIA mind-control specialists sought to emulate and surpass that kind of sophistication, as it might apply to any conceivable drug. Their fixation on the "magic mushroom" grew indirectly out of a meeting between drug experts and Morse Allen, head of the Agency's ARTICHOKE program, in October 1952. One expert told Allen about a shrub called piule, whose seeds had long been used as an intoxicant by Mexican Indians at religious ceremonies. Allen, who wanted to know about anything that distorted reality, immediately arranged for a young CIA scientist to take a Mexican field trip and gather samples of piule as well as other plants of "high narcotic and toxic value of interest to ARTICHOKE."

That young scientist arrived in Mexico City early in 1953. He could not advertise the true purpose of his trip because of ARTICHOKE's extreme secrecy, so he assumed cover as a researcher interested in finding native plants which were anesthetics. Fluent in Spanish and familiar with Mexico, he had no trouble moving around the country, meeting with leading experts on botanicals. Then he was off into the mountains south of the capital with his own field-testing equipment, gathering specimens and testing them crudely on the spot. By February, he had collected sacks full of material, including 10 pounds of piule. Before leaving Mexico to look for more samples around the Caribbean, the young scientist heard amazing tales about special mushrooms that grew only in the hot and rainy summer months. Such stories had circulated among Europeans in Mexico since Cortez had conquered the country early in the sixteenth century. Spanish friars had reported that the Aztecs used strange mushrooms in their religious ceremonies, which these converters of the heathens described as "demonic holy communions." Aztec priests called the special mushrooms *teonanacatl*, "God's flesh." But Cortez's plunderers soon lost track of the rite, as did the traders and anthropologists who followed in their wake. Only the legend survived.

Back in Washington, the young scientist's samples went straight to the labs, and Agency officials scoured the historical record for accounts of the strange mushrooms. Morse Allen himself, though responsible in ARTICHOKE research for everything from the polygraph to hypnosis, took the trouble to go through the Indian lore. "Very early accounts of the ceremonies of some tribes of Mexican Indians show that mushrooms are used to produce hallucinations and to create intoxication in connection with religious festivals," he wrote. "In addition, this literature shows that witch doctors or 'divinators' used some types of mushrooms to produce confessions or to locate stolen objects or to predict the future." Here was a possible truth drug, Morse Allen reasoned. "Since it had been determined that no area of human knowledge is to be left unexplored in connection with the ARTICHOKE program, it was therefore regarded as essential that the peculiar qualities of the mushroom be explored...." Allen declared. "Full consideration," he concluded, should be given to sending an Agency man back to Mexico during the summer. The CIA had begun its quest for "God's flesh."

Characteristically, Morse Allen was planning ahead in case the CIA's searchers came up with a mushroom worth having in large quantities. He knew that the supply from the tropics varied by season, and, anyway, it would be impractical to go to Mexico for fungi each time an operational need popped up. So Allen decided to see if it were possible to grow the mushrooms at home, either outdoors or in hothouses. On June 24, 1953, he and an associate drove from Washington to Toughkenamon, Pennsylvania, in the heart of "the largest mushroom-growing area in the world." At a three-hour session with the captains of the mushroom industry, Allen explained the government's interest in poisonous and narcotic fungi. Allen reported that the meeting "was primarily designed to obtain a 'foothold' in the center of the mushroom-growing industry where, if requirements for mushroom growing were demanded, it would be done by professionals in the trade." The mushroom executives were quite reluctant to grow toxic products because they knew that any accidental publicity would scare their customers. In the end, however, their patriotism won out, and they agreed to grow any kind of fungus the government desired. Allen considered the trip a great success.

As useful as this commitment might be, an element of chance remained as long as the CIA had to depend on the natural process. But if the Agency could find synthetic equivalents for the active ingredients, it could manufacture rather than grow its own supply. Toward this goal of bypassing nature, Morse Allen had little choice but to turn for help to the man who the following year would wrest most of the ARTICHOKE functions from his grasp: Sid Gottlieb. Gottlieb, himself a Ph.D. in chemistry, had scientists working for him who knew what to do on the level of test tubes and beakers. Allen ran ARTICHOKE out of the Office of Security, which was not equipped for work on the frontiers of science.

Gottlieb and his colleagues moved quickly into the mysteries of the Mexican hallucinogens. They went to work on the chemical structures of the piule and other plants that Morse Allen's emissary brought back from his field trip, but they neglected to report their findings to the bureaucratically outflanked Allen. Gottlieb and the MKULTRA crew soon got caught up in the search for the magic mushroom. While TSS had its own limited laboratory facilities, it depended on secret contractors for most research and development. Working with an associate, a cadaverously thin chemistry Ph.D. named Henry Bortner, Gottlieb passed the tropical plants to a string of corporate and academic researchers. One of them, Dr. James Moore, a 29-yearold chemist at Parke, Davis & Company in Detroit, was destined to be the first man in the CIA camp to taste the magic mushroom. Moore's career was typical of the specialists in the CIA's vast network of private contractors. His path to the mushroom led through several jobs and offbeat assignments, always with Agency funds and direction behind him. A precise, meticulous man of scientific habits, Moore was hardly the sort one would expect to find chasing psychedelic drugs. Such pursuits began for him in March 1953, when he had returned to his lab at Parke, Davis after a year of postdoctoral research at the University of Basel. His supervisor had called him in with an intriguing proposal: How would he like to work inside the company on a CIA contract? "Those were not particularly prosperous times, and the company was glad to get someone else to pay my salary [$8,000 a year]," notes Moore 25 years later. "If I had thought I was participating in a scheme run by a small band of mad individuals, I would have demurred."

He accepted the job.

The Agency contracted with Parke, Davis, as it did with numerous other drug companies, universities, and government agencies to develop behavioral products and poisons from botanicals. CIA-funded chemists extracted deadly substances like the arrow-poison curare from natural products, while others worked on ways to deliver these poisons most effectively, like the "nondiscernible microbioinoculator" (or dart gun) that the

Army Chemical Corps invented. CIA-connected botanists collected - and then chemists analyzed - botanicals from all over the tropics: a leaf that killed cattle, several plants deadly to fish, another leaf that caused hair to fall out, sap that caused temporary blindness, and a host of other natural products that could alter moods, dull or stimulate nerves, or generally disorient people. Among the plants Moore investigated was Jamaica dogwood, a plant used by Caribbean natives to stun fish so they could be easily captured for food. This work resulted in the isolation of several new substances, one of which Moore named "lisetin," in honor of his daughter.

Moore had no trouble adjusting to the secrecy demanded by his CIA sponsors, having worked on the Manhattan Project as a graduate student. He dealt only with his own case officer, Henry Bortner, and two or three other CIA men in TSS. Once Moore completed his chemical work on a particular substance, he turned the results over to Bortner and apparently never learned of the follow-up. Moore worked in his own little isolated compartment, and he soon recognized that the Agency preferred contractors who did not ask questions about what was going on in the next box.

In 1955 Moore left private industry for academia, moving from Detroit to the relatively placid setting of the University of Delaware in Newark. The school made him an assistant professor, and he moved into a lab in the Georgian red-brick building that housed the chemistry department. Along with his family, Moore brought his CIA contract - then worth $16,000 a year, of which he received $650 per month, with the rest going to pay research assistants and overhead. Although the Agency allowed a few top university officials to be briefed on his secret connection, Moore appeared to his colleagues and students to be a normal professor who had a healthy research grant from the Geschickter Fund for Medical Research in Washington.

In the world of natural products - particularly mushrooms - the CIA soon made Moore a full-service agent. With some help from his CIA friends, he made contact with the leading lights in mycology (the study of mushrooms), attended professional meetings, and arranged for others to send him samples. From the CIA's point of view, he could not have had better cover. As Sid Gottlieb wrote, Moore "maintains the fiction that the botanical specimens he collects are for his own use since his field interest is natural-product chemistry." Under this pretext, Moore had a perfect excuse to make and purchase for the CIA chemicals that the Agency did not want traced. Over the years, Moore billed the Agency for hundreds of purchases, including 50 cents for an unidentified pamphlet, $433.13 for a particular shipment of mescaline, $1147.60 for a large quantity of mushrooms, and $12,000 for a quarter-ton of fluothane, an inhalation anesthetic. He shipped his purchases on as Bortner directed.

Moore eventually became a kind of short-order cook for what CIA documents call "offensive CW, BW" weapons at "very low cost and in a few days' time ..." If there were an operational need, Bortner had only to call in the order, and Moore would whip up a batch of a "reputed depilatory" or hallucinogens like DMT or the incredibly potent BZ. On one occasion in 1963, Moore prepared a small dose of a very lethal carbamate poison - the same substance that OSS used two decades earlier to try to kill Adolf Hitler. Moore charged the Agency his regular consulting fee, $100, for this service.

"Did I ever consider what would have happened if this stuff were given to unwitting people?" Moore asks, reflecting on his CIA days. "No. Particularly no. Had I been given that information, I think I would have been prepared to accept that. If I had been knee-jerk about testing on unwitting subjects, I wouldn't have been the type of person they would have used. There was nothing that I did that struck me as being so sinister and deadly.... It was all investigative."

James Moore was only one of many CIA specialists on the lookout for the magic mushroom. For three years after Morse Allen's man returned from Mexico with his tales of wonder, Moore and the others in the Agency's network pushed their lines of inquiry among contacts and travelers into Mexican villages so remote that Spanish had barely penetrated. Yet they found no magic mushrooms. Given their efforts, it was ironic that the man who beat them to "God's flesh" was neither a spy nor a scientist, but a banker. It was R. Gordon Wasson, vice-president of J. P. Morgan & Company, amateur mycologist, and co-author with his wife Valentina of Mushrooms, Russia and History. Nearly 30 years earlier, Wasson and his Russian-born wife had become fascinated by the different ways that societies deal with the mushroom, and they followed their lifelong obsession with these fungi, in all their glory, all over the globe.[1] They found whole nationalities, such as the Russians and the Catalans, were mycophiles, while others like the Spaniards and the Anglo-Saxons were not.

They learned that in ancient Greece and Rome there was a belief that certain kinds of mushrooms were brought into being by lightning bolts. They discovered that widely scattered peoples, including desert Arabs, Siberians, Chinese, and Maoris of New Zealand, have shared the idea that mushrooms have supernatural connections. Their book appeared in limited edition, selling new in 1957 for $125. It contains facts and legends, lovingly told, as well as beautiful photographs of nearly every known species of mushroom.

Inevitably, the Wassons heard tell of "God's flesh," and in 1953 they started spending their vacations pursuing it. They took their first unsuccessful trek to Mexico about the time James Moore got connected to the CIA and Morse Allen met with the Pennsylvania mushroom executives. They had no luck until their third expedition, when Gordon Wasson and his traveling companion, Allan Richardson, found their holy grail high in the mountains above Oaxaca. On June 29, 1955, they entered the town hall in a village called Huautla de Jiménez. There, they found a young Indian about 35, sitting by a large table in an upstairs room. Unlike most people in the village, he spoke Spanish. "He had a friendly manner," Wasson later wrote, "and I took a chance. Leaning over the table, I asked him earnestly and in a low voice if I could speak to him in confidence. Instantly curious, he encouraged me. 'Will you,' I went on, 'help me learn the secrets of the divine mushroom?' and I used the Indian name *nti sheeto*, correctly pronouncing it with glottal stop and tonal differentiation of the syllables. When [he] recovered from his surprise he said warmly that nothing could be easier."

Shortly thereafter, the Indian led Wasson and Richardson down into a deep ravine where mushrooms were growing in abundance. The white men snapped picture after picture of the fungi and picked a cardboard boxfull. Then, in the heavy humid heat of the afternoon, the Indian led them up the mountain to a woman who performed the ancient mushroom rite. Her name was María Sabina. She was not only a curandera, or shaman, of "the highest quality," wrote Wasson, but a "señora sin mancha, a woman without stain." Wasson described her as middle-aged and short, "with a spirituality in her expression that struck us at once. She had a presence. We showed our mushrooms to the woman and her daughter. They cried out in rapture over the firmness, the fresh beauty and abundance of our young specimens. Through the interpreter we asked if they would serve us that night. They said yes."

That night, Wasson, Richardson, and about 20 Indians gathered in one of the village's adobe houses. The natives wore their best clothes and were friendly to the white strangers. The host provided chocolate drinks, which evoked for Wasson accounts of similar beverages being served early Spanish writers. María Sabina sat on a mat before a simple altar table that was adorned with the images of the Child Jesus and the Baptism in Jordan. After cleaning the mushrooms, she handed them out to all the adults present, keeping 26 for herself and giving Wasson and Richardson 12 each.

María Sabina put out the last candle about midnight, and she chanted haunting, tightly measured melodies. The Indian celebrants responded with deep feeling. Both Wasson and Richardson began to experience intense hallucinations that did not diminish until about 4:00 A.M. "We were never more wide awake, and the visions came whether our eyes were open or closed," Wasson wrote:

> They emerged from the center of the field of our vision, opening up as they came, now rushing, now slowly at the pace that our will chose. They were vivid in color, always harmonious. They began with art motifs, such as might decorate carpets or textiles or wallpaper or the drawing board of an architect. Then they evolved into palaces with courts, arcades, gardens - resplendent palaces with semiprecious stones.... Could the miraculous mobility that I was now enjoying be the explanation for the flying witches that played some important part in the folklore and fairy tales of northern Europe? These reflections passed through my mind at the very time that I was seeing the vision, for the effect of the mushrooms is to bring about a fission of the spirit, a split in the person, a kind of schizophrenia, with the rational side continuing to reason and to observe the sensations that the other side is enjoying. The mind is attached by an elastic cord to the vagrant senses.

Thus Gordon Wasson described the first known mushroom trip by "outsiders" in recorded history. The CIA's men missed the event, but they quickly learned of it, even though Wasson's visit was a private noninstitutional one to a place where material civilization had not reached. Such swiftness was assured by the breadth of the Agency's informant network, which included formal liaison arrangements with agencies like the Agriculture Department and the FDA and informal contacts all over the world. A botanist in Mexico City sent the report that reached both CIA headquarters and then James Moore. In the best bureaucratic form, the CIA description of Wasson's visions stated sparsely that the New York banker thought he saw "a multitude of architectural forms." Still, "God's flesh" had been located, and the MKULTRA leaders snatched up information that Wasson planned to return the following summer and bring back some mushrooms.

During the intervening winter, James Moore wrote Wasson - "out of the blue," as Wasson recalls - and expressed a desire to look into the chemical properties of Mexican fungi. Moore eventually suggested that he would like to accompany Wasson's party, and, to sweeten the proposition, he mentioned that he knew a foundation that might be willing to help underwrite the expedition. Sure enough, the CIA's conduit, the Geschickter Fund, made a $2,000 grant. Inside the MKULTRA program, the quest for the divine mushroom became Subproject 58.

Joining Moore and Wasson on the 1956 trip were the world-renowned French mycologist Roger Heim and a colleague from the Sorbonne. The party made the final leg of the trip, one at a time, in a tiny Cessna, but when it was Moore's turn, the load proved too much for the plane. The pilot suddenly took a dramatic right angle turn through a narrow canyon and made an unscheduled stop on the side of a hill. Immediately on landing, an Indian girl ran out and slid blocks under the wheels, so the plane would not roll back into a ravine. The pilot decided to lighten the load by leaving Moore among the local Indians, who spoke neither English nor Spanish. Later in the day, the plane returned and picked up the shaken Moore.

Finally in Huautla, sleeping on a dirt floor and eating local food, everyone reveled in the primitiveness of the adventure except Moore, who suffered. In addition to diarrhea, he recalls, "I had a terribly bad cold, we damned near starved to death, and I itched all over." Beyond his physical woes, Moore became more and more alienated from the others, who got on famously. Moore was a "complainer," according to Wasson. "He had no empathy for what was going on," recalls Wasson. "He was like a landlubber at sea. He got sick to his stomach and hated it all." Moore states, "Our relationship deteriorated during the course of the trip."

Wasson returned to the same María Sabina who had led him to the high ground the year before. Again the ritual started well after dark and, for everyone but Moore, it was an enchanted evening. Sings Wasson: "I had the most superb feeling - a feeling of ecstasy. You're raised to a height where you have not been in everyday life - not ever." Moore, on the other hand, never left the lowlands. His description: "There was all this chanting in the dialect. Then they passed the mushrooms around, and we chewed them up. I did feel the hallucinogenic effect, although 'disoriented' would be a better word to describe my reaction."

Soon thereafter, Moore returned to Delaware with a bag of mushrooms - just in time to take his pregnant wife to the hospital for delivery. After dropping her off with the obstetrician, he continued down the hall to another doctor about his digestion. Already a thin man, Moore had lost 15 pounds. Over the next week, he slowly nursed himself back to health. He reported in to Bortner and started preliminary work in his lab to isolate the active ingredient in the mushrooms. Bortner urged him on; the men from MKULTRA were excited at the prospect that they might be able to create "a completely new chemical agent." They wanted their own private supply of "God's flesh." Sid Gottlieb wrote that if Moore succeeded, it was "quite possible" that the new drugs could "remain an Agency secret."

Gottlieb's dream of a CIA monopoly on the divine mushroom vanished quickly under the influence of unwanted competitors, and indeed, the Agency soon faced a control problem of burgeoning proportions. While Moore toiled in his lab, Roger Heim in Paris unexpectedly pulled off the remarkable feat of growing the mushrooms in artificial culture from spore prints he had made in Mexico. Heim then sent samples to none other than Albert Hofmann, the discoverer of LSD, who quickly isolated and chemically reproduced the active chemical ingredient. He named it psilocybin.

The dignified Swiss chemist had beaten out the CIA,[2] and the men from MKULTRA found themselves trying to obtain formulas and supplies from overseas. Instead of locking up the world's supply of the drug in a safe somewhere, they had to keep track of disbursements from Sandoz, as they were doing with LSD. Defeated by the old master, Moore laid his own work aside and sent away to Sandoz for a supply of psilocybin.

This lapse in control still did not quash the hopes of Agency officials that the mushroom might become a powerful weapon in covert operations. Agency scientists rushed it into the experimental stage. Within three summers of the first trip with James Moore, the CIA's queasy professor from America, the mushroom had journeyed through laboratories on two continents, and its chemical essence had worked its way back to Agency conduits and a contractor who would test it. In Kentucky, Dr. Harris Isbell ordered psilocybin injected into nine black inmates at the narcotics prison. His staff laid the subjects out on beds as the drug took hold and measured physical symptoms every hour: blood pressure, knee-jerk reflexes, rectal temperature, precise diameter of eye pupils, and so on. In addition, they recorded the inmates' various subjective feelings:

> After 30 minutes, anxiety became quite definite and was expressed as consisting of fear that something evil was going to happen, fear of insanity, or of death.... At times patients had the sensation that they could see the blood and bones in their own body or in that of another person. They reported many fantasies or dreamlike states in which they seemed to be elsewhere. Fantastic experiences, such as trips to the moon or living in gorgeous castles were occasionally reported.... Two of the 9 patients ... felt their experiences were caused by the experimenters controlling their minds...

Experimental data piled up, with operational testing to follow.

But the magic mushroom never became a good spy weapon. It made people behave strangely but no one could predict where their trips would take them. Agency officials craved certainty.

On the other hand, Gordon Wasson found revelation. After a lifetime of exploring and adoring mushrooms, he had discovered the greatest wonder of all in that remote Indian village. His experience inspired him to write an account of his journey for the "Great Adventures" series in Life magazine. The story, spread across 17 pages of text and color photographs, was called "Seeking the Magic Mushroom: A New York banker goes to Mexico's mountains to participate in the age-old rituals of Indians who chew strange growths that produce visions." In 1957, before the Russian sputnik shook America later that year, Life introduced its millions of readers to the mysteries of hallucinogens, with a tone of glowing but dignified respect. Wasson wrote movingly of his long search for mushroom lore, and he became positively rhapsodic in reflecting on his Mexican "trip":

> In man's evolutionary past, as he groped his way out from his lowly past, there must have come a moment in time when he discovered the secret of the hallucinatory mushrooms. Their effect on him, as I see it, could only have been profound, a detonator to new ideas. For the mushrooms revealed to him worlds beyond the horizons known to him, in space and time, even worlds on a different plane of being, a heaven and perhaps a hell. For the credulous, primitive mind, the mushrooms must have reinforced mightily the idea of the miraculous. Many emotions are shared by men with the animal kingdom, but awe and reverence and the fear of God are peculiar to men. When we bear in mind the beatific sense of awe and ecstasy and caritas engendered by the divine mushrooms, one is emboldened to the point of asking whether they may not have planted in primitive man the very idea of God.

The article caused a sensation in the United States, where people had already been awakened to ideas like these by Aldous Huxley's The Doors of Perception. It lured waves of respectable adults - precursors of later hippie travelers - to Mexico in search of their own curanderas. (Wasson came to have mixed feelings about the response to his story, after several tiny Mexican villages were all but trampled by American tourists on the prowl for divinity.) One person whose curiosity was stimulated by the article was a young psychology professor named Timothy Leary. In 1959, in Mexico on vacation, he ate his first mushrooms. He recalls he "had no idea it was going to change my life." Leary had just been promised tenure at Harvard, but his life of conventional prestige lost appeal for him within five hours of swallowing the mushroom: "The revelation had come. The veil had been pulled back.... The prophetic call. The works. God had spoken."

Having responded to a Life article about an expedition that was partially funded by the CIA, Leary returned to a Harvard campus where students and professors had for years served as subjects for CIA- and military-funded LSD experiments. His career as a drug prophet lay before him. Soon he would be quoting in his own Kamasutra from the CIA's contractor Harold Abramson and others, brought together for scholarly drug conferences by the sometime Agency conduit, the Macy Foundation.

With LSD, as with mushrooms, the men from MKULTRA remained oblivious, for the most part, to the rebellious effect of the drug culture in the United States. "I don't think we were paying any attention to it," recalls a TSS official. The CIA's scientists looked at drugs from a different perspective and went on trying to fashion their spy arsenal. Through the entire 1960s and into the 1970s, the Agency would scour Latin America for poisonous and narcotic plants.[3] Earlier, TSS officials and contractors actually kept spreading the magic touch of drugs by forever pressing new university researchers into the field. Boston Psychopathic's Max Rinkel stirred up the interest of Rochester's Harold Hodge and told him how to get a grant from the Agency conduit, the Geschickter Fund. Hodge's group found a way to put a radioactive marker into LSD, and the MKULTRA crew made sure that the specially treated substance found its way to still more scientists. When a contractor like Harold Abramson spoke highly of the drug at a new conference or seminar, tens or hundreds of scientists, health professionals, and subjects - usually students - would wind up trying LSD.

One day in 1954, Ralph Blum, a senior at Harvard on his way to a career as a successful author, heard from a friend that doctors at Boston Psychopathic would pay $25 to anyone willing to spend a day as a happy schizophrenic. Blum could not resist. He applied, passed the screening process, took a whole battery of Wechsler psychological tests, and was told to report back on a given morning. That day, he was shown into a room with five other Harvard students. Project director Bob Hyde joined them and struck Blum as a reassuring father figure. Someone brought in a tray with six little glasses full of water and LSD. The students drank up. For Blum, the drug did not take hold for about an hour and a half - somewhat longer than the average. While Hyde was in the process of interviewing him, Blum felt his mind shift gears. "I looked at the clock on the wall and thought how well behaved it was. It didn't pay attention to itself. It just stayed on the wall and told time." Blum felt that he was looking at everything around him from a new perspective. "It was a very subtle thing," he says. "My ego filter had been pretty much removed. I turned into a very accessible state - accessible to myself. I knew when someone was lying to me, and the richness of the experience was such that I didn't want to suffer fools gladly." Twenty-four years later, Blum concludes: "It was undeniably a very important experience for me. It made a difference in my life. It began to move the log jam of my old consciousness. You can't do it with just one blast. It was the beginning of realizing it was safe to love again. Although I wouldn't use them until much later, it gave me a new set of optics. It let me know there was something downstream."[4]

Many student subjects like Blum thought LSD transformed the quality of their lives. Others had no positive feelings, and some would later use the negative memories of their trips to invalidate the whole drug culture and stoned thinking process of the 1960s. In a university city like Boston where both the CIA and the Army were carrying on large testing programs at hospitals connected to Harvard, volunteering for an LSD trip became quite popular in academic circles. Similar reactions, although probably not as pronounced, occurred in other intellectual centers. The intelligence agencies turned to America's finest universities and hospitals to try LSD, which meant that the cream of the country's students and graduate assistants became the test subjects.

In 1969 the Bureau of Narcotics and Dangerous Drugs published a fascinating little study designed to curb illegal LSD use. The authors wrote that the drug's "early use was among small groups of intellectuals at large Eastern and West Coast universities. It spread to undergraduate students, then to other campuses. Most often, users have been introduced to the drug by persons of higher status. Teachers have influenced students; upperclassmen have influenced lower-classmen." Calling this a "trickle-down phenomenon," the authors seem to have correctly analyzed how LSD got around the country. They left out only one vital element, which they had no way of knowing: That somebody had to influence the teachers and that up there at the top of the LSD distribution system could be found the men of MKULTRA.

Harold Abramson apparently got a great kick out of getting his learned friends high on LSD. He first turned on Frank Fremont-Smith, head of the Macy Foundation which passed CIA money to Abramson. In this cozy little world where everyone knew everybody, Fremont-Smith organized the conferences that spread the word about LSD to the academic hinterlands. Abramson also gave Gregory Bateson, Margaret Mead's former husband, his first LSD. In 1959 Bateson, in turn, helped arrange for a beat poet friend of his named Allen Ginsberg to take the drug at a research program located of f the Stanford campus. No stranger to the hallucinogenic effects of peyote, Ginsberg reacted badly to what he describes as "the closed little doctor's room full of instruments," where he took the drug. Although he was allowed to listen to records of his choice (he chose a Gertrude Stein reading, a Tibetan mandala, and Wagner), Ginsberg felt he "was being connected to Big Brother's brain." He says that the experience resulted in "a slight paranoia that hung on all my acid experiences through the mid-1960s until I learned from meditation how to disperse that."

Anthropologist and philosopher Gregory Bateson then worked at the Veterans Administration Hospital in Palo Alto. From 1959 on, Dr. Leo Hollister was testing LSD at that same hospital. Hollister says he entered the hallucinogenic field reluctantly because of the "unscientific" work of the early LSD researchers. He refers specifically to most of the people who attended Macy conferences. Thus, hoping to improve on CIA and military-funded work, Hollister tried drugs out on student volunteers, including a certain Ken Kesey, in 1960. Kesey said he was a jock who had only been drunk once before, but on three successive Tuesdays, he tried different psychedelics. "Six weeks later I'd bought my first ounce of grass," Kesey later wrote, adding, "Six months later I had a job at that hospital as a psychiatric aide." Out of that experience, using drugs while he wrote, Kesey turned out One Flew Over the Cuckoo's Nest. He went on to become the counterculture's second most famous LSD visionary, spreading the creed throughout the land, as Tom Wolfe would chronicle in The Electric Kool-Aid Acid Test.

CIA officials never meant that the likes of Leary, Kesey, and Ginsberg should be turned on. Yet these men were, and they, along with many of the lesser-known experimental subjects, like Harvard's Ralph Blum, created the climate whereby LSD escaped the government's control and became available by the early sixties on the black market. No one at the Agency apparently foresaw that young Americans would voluntarily take the drug - whether for consciousness expansion or recreational purposes. The MKULTRA experts were mainly on a control trip, and they proved incapable of gaining insight from their own LSD experiences of how others less fixated on making people do their bidding would react to the drug.

It would be an exaggeration to put all the blame on - or give all the credit to - the CIA for the spread of LSD. One cannot forget the nature of the times, the Vietnam War, the breakdown in authority, and the wide availability of other drugs, especially marijuana. But the fact remains that LSD was one of the catalysts of the traumatic upheavals of the 1960s. No one could enter the world of psychedelics without first passing, unawares, through doors opened by the Agency. It would become a supreme irony that the CIA's enormous search for weapons among drugs - fueled by the hope that spies could, like Dr. Frankenstein, control life with genius and machines - would wind up helping to create the wandering, uncontrollable minds of the counterculture.

Notes 7

R. Gordon and Valentina Wasson's mammoth work, Mushrooms, Russia and History, (New York: Pantheon, 1957), was the source for the account of the Empress Agrippina's murderous use of mushrooms. Wasson told the story of his various journeys to Mexico in a series of interviews and in a May 27, 1957 Life magazine article, "Seeking the Magic Mushroom."

Morse Allen learned of piule in a sequence described in document #A/B,I,33/7, 14 November 1952, Subject: Piule. The sending of the young CIA scientist to Mexico was outlined in #A/B, I,33/3,5 December 1952. Morse Allen commented on mushroom history and covert possibilities in #A/B, I, 34/4, 26 June 1953, Subject: Mushrooms - Narcotic and Poisonous Varieties. His trip to the American mushroom-growing capital was described in Document Number illegible], 25 June 1953, Subject: Trip to Toughkenamon, Pennsylvania. The failure of TSS to tell Morse Allen about the results of the botanical lab work is outlined in #A/B, I, 39/5, 10 August 1954 Subject: Reports; Request for from TSS [deleted].

James Moore told much about himself in a long interview and in an exchange of correspondence. MKULTRA Subproject 51 dealt with Moore's consulting relationship with the Agency and Subproject 52 with his ties as a procurer of chemicals. See especially Document 51-46, 8 April 1963, Subject: MKULTRA Subproject 51; 51-24, 27 August 1956, Subject: MKULTRA Subproject 51-B; 52-94, 20 February 1963, Subject: (BB) Chemical and Physical Manipulants; 52-19, 20 December 1962; 52-17, 1 March 1963; 52-23, 6 December 1962; 52-64, 24 August 1959.

The CIA's arrangements with the Department of Agriculture are detailed in #A/B, I, 34/4, 26 June, 1953, Subject: Mushrooms - Narcotic and Poisonous varieties and Document [number illegible], 13 April 1953, Subject: Interview with Cleared Contacts.

Dr. Harris Isbell's work with psilocybin is detailed in Isbell document # 155, "Comparison of the Reaction Induced by Psilocybin and LSD-25 in Man."

Information on the counterculture and its interface with CIA drug-testing came from interviews with Timothy Leary, Allen Ginsburg, Humphrey Osmond, John Lilly, Sidney Cohen, Ralph Blum, Herbert Kelman, Leo Hollister, Herbert DeShon, and numerous others. Ken Kesey described his first trip in Garage Sale (New York: Viking Press, 1973). Timothy Leary's Kamasutra was actually a book hand-produced in four copies and called Psychedelic Theory: Working Papers from the Harvard IFlF Psychedelic Research Project, 1960-1963. Susan Berns Wolf Rothchild kindly made her copy available. The material about Harold Abramson's turning on Frank Fremont-Smith and Gregory Bateson came from the proceedings of a conference on LSD sponsored by the Josiah Macy, Jr. Foundation on April 22, 23, and 24, 1959, pp. 8-22.

Footnotes 7

1. On their honeymoon, in the summer of 1927, the Wassons were strolling along a mountain path when suddenly Valentina abandoned Gordon's side. "She had spied wild mushrooms in the forest," wrote Wasson, "and racing over the carpet of dried leaves in the woods, she knelt in poses of adoration before one cluster and then another of these growths. In ecstasy she called each kind by an endearing Russian name. Like all good Anglo-Saxons, I knew nothing about the fungal world and felt the less I knew about these putrid, treacherous excrescences the better. For her they were things of grace infinitely inviting to the perceptive mind." In spite of his protests, Valentina gathered up the mushrooms and brought them back to the lodge were she cooked them for dinner. She ate them all - alone. Wasson wanted no part of the fungi. While she mocked his horror, he predicted in the face of her laughter he would wake up a widower the next morning. When Valentina survived, the couple decided to find an explanation for "the strange cultural cleavage" that had caused them to react so differently to mushrooms. From then on, they were hooked, and the world became the richer.
2. Within two years, Albert Hofmann would scoop the CIA once again, with some help from Gordon Wasson. In 1960 Hofmann broke down and chemically recreated the active ingredient in hallucinatory ololiuqui seeds sent him by Wasson before the Agency's contractor, William Boyd Cook of Montana State University, could do the job. Hofmann's and Wasson's professional relationship soon grew into friendship, and in 1962 they traveled together on horseback to Huautla de Jiménez to visit María Sabina. Hofmann presented the curandera with some genuine Sandoz psilocybin. Wasson recalls: "Of course, Albert Hofmann is so conservative he always gives too little a dose, and it didn't have any effect." The crestfallen Hofmann believed he had duplicated "God's flesh," and he doubled the dose. Then María Sabina had her customary visions, and she reported, according to Wasson, the drug was the "same" as the mushroom. States Wasson, whose prejudice for real mushrooms over chemicals is unmistakable, "I don't think she said it with very much enthusiasm."
3. See Chapter 12.
4. Lincoln Clark, a psychiatrist who tested LSD for the Army at Massachusetts General Hospital, reflects a fairly common view among LSD researchers when he belittles drug-induced thinking of the sort described by Blum. "Everybody who takes LSD has an incredible experience that you can look at as having positive characteristics. I view it as pseudo-insight. This is part of the usual response of intellectually pretentious people." On the other hand, psychiatrist Sidney Cohen, who has written an important book on LSD, noted that to experience a visionary trip, "the devotee must have faith in, or at least be open to the possibility of the 'other state.' ... He must 'let go,' not offer too much resistance to losing his personal identity. The ability to surrender oneself is probably the most important operation of all."

Part III - Spells - electrodes and hypnosis

8. Brainwashing

In September 1950, the Miami News published an article by Edward Hunter titled " 'Brain-Washing' Tactics Force Chinese into Ranks of Communist Party." It was the first printed use in any language of the term "brainwashing," which quickly became a stock phrase in Cold War headlines. Hunter, a CIA propaganda operator who worked under cover as a journalist, turned out a steady stream of books and articles on the subject. He made up his coined word from the Chinese hsi-nao - "to cleanse the mind" - which had no political meaning in Chinese.

American public opinion reacted strongly to Hunter's ideas, no doubt because of the hostility that prevailed toward communist foes, whose ways were perceived as mysterious and alien. Most Americans knew something about the famous trial of the Hungarian Josef Cardinal Mindszenty, at which the Cardinal appeared zombie-like, as though drugged or hypnotized. Other defendants at Soviet "show trials" had displayed similar symptoms as they recited unbelievable confessions in dull, cliché- ridden monotones. Americans were familiar with the idea that the communists had ways to control hapless people, and Hunter's new word helped pull together the unsettling evidence into one sharp fear. The brainwashing controversy intensified during the heavy 1952 fighting in Korea, when the Chinese government launched a propaganda offensive that featured recorded statements by captured U.S. pilots, who "confessed" to a variety of war crimes including the use of germ warfare.

The official American position on prisoner confessions was that they were false and forced. As expressed in an Air Force Headquarters document, "Confessions can be of truthful details.... For purposes of this section, 'confessions' are considered as being the forced admission to a lie." But if the military had understandable reasons to gloss over the truth or falsity of the confessions, this still did not address the fact that confessions had been made at all. Nor did it lay to rest the fears of those like Edward Hunter who saw the confessions as proof that the communists now had techniques "to put a man's mind into a fog so that he will mistake what is true for what is untrue, what is right for what is wrong, and come to believe what did not happen actually had happened, until he ultimately becomes a robot for the Communist manipulator."

By the end of the Korean War, 70 percent of the 7,190 U.S. prisoners held in China had either made confessions or signed petitions calling for an end to the American war effort in Asia. Fifteen percent collaborated fully with the Chinese, and only 5 percent steadfastly resisted. The American performance contrasted poorly with that of the British, Australian, Turkish, and other United Nations prisoners - among whom collaboration was rare, even though studies showed they were treated about as badly as the Americans. Worse, an alarming number of the prisoners stuck by their confessions after returning to the United States. They did not, as expected, recant as soon as they stepped on U.S. soil. Puzzled and dismayed by this wholesale collapse of morale among the POWs, American opinion leaders settled in on Edward Hunter's explanation: The Chinese had somehow brainwashed our boys.

But how? At the height of the brainwashing furor, conservative spokesmen often seized upon the very mystery of it all to give a religious cast to the political debate. All communists have been, by definition, brainwashed through satanic forces, they argued - thereby making the enemy seem like robots completely devoid of ordinary human feelings and motivation. Liberals favored a more scientific view of the problem. Given the incontrovertible evidence that the Russians and the Chinese could, in a very short time and often under difficult circumstances, alter the basic belief and behavior patterns of both domestic and foreign captives, liberals argued that there must be a technique involved that would yield its secrets under objective investigation.

CIA Director Allen Dulles favored the scientific approach, although he naturally encouraged his propaganda experts to exploit the more emotional interpretations of brainwashing. Dulles and the heads of the other American security agencies became almost frantic in their efforts to find out more about the Soviet and Chinese successes in mind control. Under pressure for answers, Dulles turned to Dr. Harold Wolff, a world-famous neurologist with whom he had developed an intensely personal relationship. Wolff was then treating Dulles' own son for brain damage suffered from a Korean War head wound. Together they shared the trauma of the younger Dulles' fits and mental lapses. Wolff, a skinny little doctor with an overpowering personality, became fast friends with the tall, patrician CIA Director. Dulles may have seen brainwashing as an induced form of brain damage or mental illness. In any case, in late 1953, he asked Wolff to conduct an official study of communist brainwashing techniques for the CIA. Wolff, who had become fascinated by the Director's tales of the clandestine world, eagerly accepted.

Harold Wolff was known primarily as an expert on migraine headaches and pain, but he had served on enough military and intelligence advisory panels that he knew how to pick up Dulles' mandate and expand on it. He formed a working partnership with Lawrence Hinkle, his colleague at Cornell University Medical College in New York City. Hinkle handled the administrative part of the study and shared in the substance. Before going ahead, the two doctors made sure they had the approval of Cornell's president, Deane W. Malott and other high university officials who checked with their contacts in Washington to make sure the project did indeed have the great importance that Allen Dulles stated. Hinkle recalls a key White House aide urging Cornell to cooperate. The university administration agreed, and soon Wolff and Hinkle were poring over the Agency's classified files on brainwashing. CIA officials also helped arrange interviews with former communist interrogators and prisoners alike. "It was done with great secrecy," recalls Hinkle. "We went through a great deal of hoop-de-do and signed secrecy agreements, which everyone took very seriously."

The team of Wolff and Hinkle became the chief brainwashing studiers for the U.S. government, although the Air Force and Army ran parallel programs.[1] Their secret report to Allen Dulles, later published in a declassified version, was considered the definitive U.S. Government work on the subject. In fact, if allowances are made for the Cold War rhetoric of the fifties, the Wolff-Hinkle report still remains one of the better accounts of the massive political re-education programs in China and the Soviet Union. It stated flatly that neither the Soviets nor the Chinese had any magical weapons - no drugs, exotic mental ray-guns, or other fanciful machines. Instead, the report pictured communist interrogation methods resting on skillful, if brutal, application of police methods. Its portrait of the Soviet system anticipates, in dry and scholarly form, the work of novelist Alexander Solzhenitzyn in The Gulag Archipelago. Hinkle and Wolff showed that the Soviet technique rested on the cumulative weight of intense psychological pressure and human weakness, and this thesis alone earned the two Cornell doctors the enmity of the more right-wing CIA officials such as Edward Hunter. Several of his former acquaintances remember that Hunter was fond of saying that the Soviets brainwashed people the way Pavlov had conditioned dogs.

In spite of some dissenters like Hunter, the Wolff-Hinkle model became, with later refinements, the best available description of extreme forms of political indoctrination. According to the general consensus, the Soviets started a new prisoner off by putting him in solitary confinement. A rotating corps of guards watched him constantly, humiliating and demeaning him at every opportunity and making it clear he was totally cut off from all outside support. The guards ordered him to stand for long periods, let him sit, told him exactly the position he could take to lie down, and woke him if he moved in the slightest while sleeping. They banned all outside stimuli - books, conversation, or news of the world.

After four to six weeks of this mind-deadening routine, the prisoner usually found the stress unbearable and broke down. "He weeps, he mutters, and prays aloud in his cell," wrote Hinkle and Wolff. When the prisoner reached this stage, the interrogation began. Night after night, the guards brought him into a special room to face the interrogator. Far from confronting his captive with specific misdeeds, the interrogator told him that he knew his own crimes - all too well. In the most harrowing Kafkaesque way, the prisoner tried to prove his innocence to he knew not what. Together the interrogator and prisoner reviewed the prisoner's life in detail. The interrogator seized on any inconsistency - no matter how minute - as further evidence of guilt, and he laughed at the prisoner's efforts to justify himself. But at least the prisoner was getting a response of some sort. The long weeks of isolation and uncertainty had made him grateful for human contact even grateful that his case was moving toward resolution. True, it moved only as fast as he was willing to incriminate himself, but ... Gradually, he came to see that he and his interrogator were working toward the same goal of wrapping up his case. In tandem, they ransacked his soul. The interrogator would periodically let up the pressure. He offered a cigarette, had a friendly chat, explained he had a job to do - making it all the more disappointing the next time he had to tell the prisoner that his confession was unsatisfactory.

As the charges against him began to take shape, the prisoner realized that he could end his ordeal only with a full confession. Otherwise the grueling sessions would go on forever. "The regimen of pressure has created an overall discomfort which is well nigh intolerable," wrote Hinkle and Wolff. "The prisoner invariably feels that 'something must be done to end this.' He must find a way out." A former KGB officer, one of many former interrogators and prisoners interviewed for the CIA study, said that more than 99 percent of all prisoners signed a confession at this stage.

In the Soviet system under Stalin, these confessions were the final step of the interrogation process, and the prisoners usually were shot or sent to a labor camp after sentencing. Today, Russian leaders seem much less insistent on exacting confessions before jailing their foes, but they still use the penal (and mental health) system to remove from the population classes of people hostile to their rule.

The Chinese took on the more ambitious task of re-educating their prisoners. For them, confession was only the beginning. Next, the Chinese authorities moved the prisoner into a group cell where his indoctrination began. From morning to night, he and his fellow prisoners studied Marx and Mao, listened to lectures, and engaged in self-criticism. Since the progress of each member depended on that of his cellmates, the group pounced on the slightest misconduct as an indication of backsliding. Prisoners demonstrated the zeal of their commitment by ferociously attacking deviations. Constant intimacy with people who reviled him pushed the resistant prisoner to the limits of his emotional endurance. Hinkle and Wolff found that "The prisoner must conform to the demands of the group sooner or later." As the prisoner developed genuine changes of attitude, pressure on him relaxed. His cellmates rewarded him with increasing acceptance and esteem. Their acceptance, in turn, reinforced his commitment to the Party, for he learned that only this commitment allowed him to live successfully in the cell. In many cases, this process produced an exultant sense of mission in the prisoner - a feeling of having finally straightened out his life and come to the truth. To be sure, this experience, which was not so different from religious conversion, did not occur in all cases or always last after the prisoner returned to a social group that did not reinforce it.

From the first preliminary studies of Wolff and Hinkle, the U.S. intelligence community moved toward the conclusion that neither the Chinese nor the Russians made appreciable use of drugs or hypnosis, and they certainly did not possess the brainwashing equivalent of the atomic bomb (as many feared). Most of their techniques were rooted in age-old methods, and CIA brainwashing researchers like psychologist John Gittinger found themselves poring over ancient documents on the Spanish Inquisition. Furthermore, the communists used no psychiatrists or other behavioral scientists to devise their interrogation system. The differences between the Soviet and Chinese systems seemed to grow out of their respective national cultures. The Soviet brainwashing system resembled a heavy-handed cop whose job was to isolate, break, and then subdue all the troublemakers in the neighborhood. The Chinese system was more like thousands of skilled acupuncturists, working on each other and relying on group pressure, ideology, and repetition. To understand further the Soviet or Chinese control systems, one had to plunge into the subtle mysteries of national and individual character.

While CIA researchers looked into those questions, the main thrust of the Agency's brainwashing studies veered off in a different direction. The logic behind the switch was familiar in the intelligence business. Just because the Soviets and the Chinese had not invented a brainwashing machine, officials reasoned, there was no reason to assume that the task was impossible. If such a machine were even remotely feasible, one had to assume the communists might discover it. And in that case, national security required that the United States invent the machine first. Therefore, the CIA built up its own elaborate brainwashing program, which, like the Soviet and Chinese versions, took its own special twist from our national character. It was a tiny replica of the Manhattan Project, grounded in the conviction that the keys to brainwashing lay in technology. Agency officials hoped to use old-fashioned American know-how to produce shortcuts and scientific breakthroughs. Instead of turning to tough cops, whose methods repelled American sensibilities, or the gurus of mass motivation, whose ideology Americans lacked, the Agency's brainwashing experts gravitated to people more in the mold of the brilliant - and sometimes mad - scientist, obsessed by the wonders of the brain.

In 1953 CIA Director Allen Dulles made a rare public statement on communist brainwashing: "We in the West are somewhat handicapped in getting all the details," Dulles declared. "There are few survivors, and we have no human guinea pigs to try these extraordinary techniques." Even as Dulles spoke, however, CIA officials acting under his orders had begun to find the scientists and the guinea pigs. Some of their experiments would wander so far across the ethical borders of experimental psychiatry (which are hazy in their own right) that Agency officials thought it prudent to have much of the work done outside the United States.

Call her Lauren G. For 19 years, her mind has been blank about her experience. She remembers her husband's driving her up to the old gray stone mansion that housed the hospital, Allan Memorial Institute, and putting her in the care of its director, Dr. D. Ewen Cameron. The next thing she recalls happened three weeks later:

> They gave me a dressing gown. It was way too big, and I was tripping all over it. I was mad. I asked why did I have to go round in this sloppy thing. I could hardly move because I was pretty weak. I remember trying to walk along the hall, and the walls were all slanted. It was then that I said, "Holy Smokes, what a ghastly thing." I remember running out the door and going up the mountain in my long dressing gown.

The mountain, named Mont Royal, loomed high above Montreal. She stumbled and staggered as she tried to climb higher and higher. Hospital staff members had no trouble catching her and dragging her back to the Institute. In short order, they shot her full of sedatives, attached electrodes to her temples, and gave her a dose of electroshock. Soon she slept like a baby.

Gradually, over the next few weeks, Lauren G. began to function like a normal person again. She took basket-weaving therapy and played bridge with her fellow patients. The hospital released her, and she returned to her husband in another Canadian city.

Before her mental collapse in 1959, Lauren G. seemed to have everything going for her. A refined, glamorous horsewoman of 30, whom people often said looked like Elizabeth Taylor, she had auditioned for the lead in National Velvet at 13 and married the rich boy next door at 20. But she had never loved her husband and had let her domineering mother push her into his arms. He drank heavily. "I was really unhappy," she recalls. "I had a horrible marriage, and finally I had a nervous breakdown. It was a combination of my trying to lose weight, sleep loss, and my nerves."

The family doctor recommended that her husband send her to Dr. Cameron, which seemed like a logical thing to do, considering his wide fame as a psychiatrist. He had headed Allan Memorial since 1943, when the Rockefeller Foundation had donated funds to set up a psychiatric facility at McGill University. With continuing help from the Rockefellers, McGill had built a hospital known far beyond Canada's borders as innovative and exciting. Cameron was elected president of the American Psychiatric Association in 1953, and he became the first president of the World Psychiatric Association. His friends joked that they had run out of honors to give him.

Cameron's passion lay in the more "objective" forms of therapy, with which he could more easily and swiftly bring about improvements in patients than with the notoriously slow Freudian methods. An impatient man, he dreamed of finding a cure for schizophrenia. No one could tell him he was not on the right track. Cameron's supporter at the Rockefeller Foundation, Robert Morrison, recorded in his private papers that he found the psychiatrist tense and ill-at-ease, and Morrison ventured that this may account for "his lack of interest and effectiveness in psychotherapy and failure to establish warm personal relations with faculty members, both of which were mentioned repeatedly when I visited Montreal." Another Rockefeller observer noted that Cameron "appears to suffer from deep insecurity and has a need for power which he nourishes by maintaining an extraordinary aloofness from his associates."

When Lauren G.'s husband delivered her to Cameron, the psychiatrist told him she would receive some electroshock, a standard treatment at the time. Besides that, states her husband, "Cameron was not very communicative, but I didn't think she was getting anything out of the ordinary." The husband had no way of knowing that Cameron would use an unproved experimental technique on his wife - much less that the psychiatrist intended to "depattern" her. Nor did he realize that the CIA was supporting this work with about $19,000 a year in secret funds.[2]

Cameron defined "depatterning" as breaking up existing patterns of behavior, both the normal and the schizophrenic, by means of particularly intensive electroshocks, usually combined with prolonged, drug-induced sleep. Here was a psychiatrist willing - indeed, eager - to wipe the human mind totally clean. Back in 1951, ARTICHOKE's Morse Allen had likened the process to "creation of a vegetable." Cameron justified this tabula rasa approach because he had a theory of "differential amnesia," for which he provided no statistical evidence when he published it. He postulated that after he produced "complete amnesia" in a subject, the person would eventually recover memory of his normal but not his schizophrenic behavior. Thus, Cameron claimed he could generate "differential amnesia." Creating such a state in which a man who knew too much could be made to forget had long been a prime objective of the ARTICHOKE and MKULTRA programs.

Needless to say, Lauren G. does not recall a thing today about those weeks when Cameron depatterned her. Afterward, unlike over half of the psychiatrist's depatterning patients, Lauren G. gradually recovered full recall of her life before the treatment, but then, she remembered her mental problems, too.[3] Her husband says she came out of the hospital much improved. She declares the treatment had no effect one way or another on her mental condition, which she believes resulted directly from her miserable marriage. She stopped seeing Cameron after about a month of outpatient electroshock treatments, which she despised. Her relationship with her husband further deteriorated, and two years later she walked out on him. "I just got up on my own hind legs," she states. "I said the hell with it. I'm going to do what I want and take charge of my own life. I left and started over." Now divorced and remarried, she feels she has been happy ever since.

Cameron's depatterning, of which Lauren G. had a comparatively mild version, normally started with 15 to 30 days of "sleep therapy." As the name implies, the patient slept almost the whole day and night. According to a doctor at the hospital who used to administer what he calls the "sleep cocktail," a staff member woke up the patient three times a day for medication that consisted of a combination of 100 mg. Thorazine, 100 mg. Nembutal, 100 mg. Seconal, 150 mg. Veronal, and 10 mg. Phenergan. Another staff doctor would also awaken the patient two or sometimes three times daily for electroshock treatments.[4] This doctor and his assistant wheeled a portable machine into the "sleep room" and gave the subject a local anesthetic and muscle relaxant, so as not to cause damage with the convulsions that were to come. After attaching electrodes soaked in saline solution, the attendant held the patient down and the doctor turned on the current. In standard, professional electroshock, doctors gave the subject a single dose of 110 volts, lasting a fraction of a second, once a day or every other day. By contrast, Cameron used a form 20 to 40 times more intense, two or three times daily, with the power turned up to 150 volts. Named the "Page-Russell" method after its British originators, this technique featured an initial one-second shock, which caused a major convulsion, and then five to nine additional shocks in the middle of the primary and follow-on convulsions. Even Drs. Page and Russell limited their treatment to once a day, and they always stopped as soon as their patient showed "pronounced confusion" and became "faulty in habits." Cameron, however, welcomed this kind of impairment as a sign the treatment was taking effect and plowed ahead through his routine.

The frequent screams of patients that echoed through the hospital did not deter Cameron or most of his associates in their attempts to "depattern" their subjects completely. Other hospital patients report being Petrified by the "sleep rooms," where the treatment took place, and they would usually creep down the opposite side of the hall.

Cameron described this combined sleep-electroshock treatment as lasting between 15 to 30 days, with some subjects staying in up to 65 days (in which case, he reported, he awakened them for three days in the middle). Sometimes, as in the case of Lauren G., patients would try to escape when the sedatives wore thin, and the staff would have to chase after them. "It was a tremendous nursing job just to keep these people going during the treatment," recalls a doctor intimately familiar with Cameron's operation. This doctor paints a picture of dazed patients, incapable of taking care of themselves, often groping their way around the hospital and urinating on the floor.

Cameron wrote that his typical depatterning patient - usually a woman - moved through three distinct stages. In the first, the subject lost much of her memory. Yet she still knew where she was, why she was there, and who the people were who treated her. In the second phase, she lost her "space-time image," but still wanted to remember. In fact, not being able to answer questions like, "Where am I?" and "How did I get here?" caused her considerable anxiety. In the third stage, all that anxiety disappeared. Cameron described the state as "an extremely interesting constriction of the range of recollections which one ordinarily brings in to modify and enrich one's statements. Hence, what the patient talks about are only his sensations of the moment, and he talks about them almost exclusively in highly concrete terms. His remarks are entirely uninfluenced by previous recollections - nor are they governed in any way by his forward anticipations. He lives in the immediate present. All schizophrenic symptoms have disappeared. There is complete amnesia for all events in his life."

Lauren G. and 52 other subjects at Allan Memorial received this level of depatterning in 1958 and 1959. Cameron had already developed the technique when the CIA funding started. The Agency sent the psychiatrist research money to take the treatment beyond this point. Agency officials wanted to know if, once Cameron had produced the blank mind, he could then program in new patterns of behavior, as he claimed he could. As early as 1953 - the year he headed the American Psychiatric Association - Cameron conceived a technique he called "psychic driving," by which he would bombard the subject with repeated verbal messages. From tape recordings based on interviews with the patient, he selected emotionally loaded "cue statements" - first negative ones to get rid of unwanted behavior and then positive to condition in desired personality traits. On the negative side, for example, the patient would hear this message as she lay in a stupor:

> Madeleine, you let your mother and father treat you as a child all through your single life. You let your mother check you up sexually after every date you had with a boy. You hadn't enough determination to tell her to stop it. You never stood up for yourself against your mother or father but would run away from trouble.... They used to call you "crying Madeleine." Now that you have two children, you don't seem to be able to manage them and keep a good relationship with your husband. You are drifting apart. You don't go out together. You have not been able to keep him interested sexually.

Leonard Rubenstein, Cameron's principal assistant, whose entire salary was paid from CIA-front funds, put the message on a continuous tape loop and played it for 16 hours every day for several weeks. An electronics technician, with no medical or psychological background, Rubenstein, an electrical whiz, designed a giant tape recorder that could play 8 loops for 8 patients at the same time. Cameron had the speakers installed literally under the pillows in the "sleep rooms." "We made sure they heard it," says a doctor who worked with Cameron. With some patients, Cameron intensified the negative effect by running wires to their legs and shocking them at the end of the message.

When Cameron thought the negative "psychic driving" had gone far enough, he switched the patient over to 2 to 5 weeks of positive tapes:

> You mean to get well. To do this you must let your feelings come out. It is all right to express your anger.... You want to stop your mother bossing you around. Begin to assert yourself first in little things and soon you will be able to meet her on an equal basis. You will then be free to be a wife and mother just like other women.

Cameron wrote that psychic driving provided a way to make "direct, controlled changes in personality," without having to resolve the subject's conflicts or make her relive past experiences. As far as is known, no present-day psychologist or psychiatrist accepts this view. Dr. Donald Hebb, who headed McGill's psychology department at the time Cameron was in charge of psychiatry, minces no words when asked specifically about psychic driving: "That was an awful set of ideas Cameron was working with. It called for no intellectual respect. If you actually look at what he was doing and what he wrote, it would make you laugh. If I had a graduate student who talked like that, I'd throw him out." Warming to his subject, Hebb continues: "Look, Cameron was no good as a researcher.... He was eminent because of politics." Nobody said such things at the time, however. Cameron was a very powerful man.

The Scottish-born psychiatrist, who never lost the burr in his voice, kept searching for ways to perfect depatterning and psychic driving. He held out to the CIA front - the Society for the Investigation of Human Ecology - that he could find more rapid and less damaging ways to break down behavior. He sent the Society a proposal that combined his two techniques with sensory deprivation and strong drugs. His smorgasbord approach brought together virtually all possible techniques of mind control, which he tested individually and together. When his Agency grant came through in 1957, Cameron began work on sensory deprivation.

For several years, Agency officials had been interested in the interrogation possibilities of this technique that Hebb himself had pioneered at McGill with Canadian defense and Rockefeller money. It consisted of putting a subject in a sealed environment - a small room or even a large box - and depriving him of all sensory input: eyes covered with goggles, ears either covered with muffs or exposed to a constant, monotonous sound, padding to prevent touching, no smells - with this empty regime interrupted only by meal and bathroom breaks. In 1955 Morse Allen of ARTICHOKE made contact at the National Institutes of Health with Dr.

Maitland Baldwin who had done a rather gruesome experiment in which an Army volunteer had stayed in the "box" for 40 hours until he kicked his way out after, in Baldwin's words, "an hour of crying loudly and sobbing in a most heartrending fashion." The experiment convinced Baldwin that the isolation technique could break any man, no matter how intelligent or strong-willed. Hebb, who unlike Baldwin released his subjects when they wanted, had never left anyone in "the box" for more than six days. Baldwin told Morse Allen that beyond that sensory deprivation would almost certainly cause irreparable damage. Nevertheless, Baldwin agreed that if the Agency could provide the cover and the subjects, he would do, according to Allen's report, "terminal type" experiments. After numerous meetings inside the CIA on how and where to fund Baldwin, an Agency medical officer finally shot down the project as being "immoral and inhuman," suggesting that those pushing the experiments might want to "volunteer their heads for use in Dr. Baldwin's 'noble' project."

With Cameron, Agency officials not only had a doctor willing to perform terminal experiments in sensory deprivation, but one with his own source of subjects. As part of his CIA-funded research, he had a "box" built in the converted stables behind the hospital that housed Leonard Rubenstein and his behavioral laboratory. Undaunted by the limits set in Hebb's work, Cameron left one woman in for 35 days, although he had so scrambled her mind with his other techniques that one cannot say, as Baldwin predicted to the Agency, if the prolonged deprivation did specific damage. This subject's name was Mary C., and, try as he might, Cameron could not get through to her. As the aloof psychiatrist wrote in his notes: "Although the patient was prepared by both prolonged sensory isolation (35 days) and by repeated depatterning, and although she received 101 days of positive driving, no favorable results were obtained."[5] Before prescribing this treatment, Cameron had diagnosed the 52-year-old Mary C.: "Conversion reaction in a woman of the involutional age with mental anxiety; hypochondriatic." In other words, Mary C. was going through menopause.

In his proposal to the CIA front, Cameron also said he would test curare, the South American arrow poison which, when liberally applied, kills by paralyzing internal body functions. In nonlethal doses, curare causes a limited paralysis which blocks but does not stop these functions. According to his papers, some of which wound up in the archives of the American Psychiatric Association, Cameron injected subjects with curare in conjunction with sensory deprivation, presumably to immobilize them further.

Cameron also tested LSD in combination with psychic driving and other techniques. In late 1956 and early 1957, one of his subjects was Val Orlikow, whose husband David has become a member of the Canadian parliament. Suffering from what she calls a "character neurosis that started with postpartum depression," she entered Allan Memorial as one of Cameron's personal patients. He soon put her under his version of LSD therapy. One to four times a week, he or another doctor would come into her room and give her a shot of LSD, mixed with either a stimulant or a depressant and then leave her alone with a tape recorder that played excerpts from her last session with him. As far as is known, no other LSD researcher ever subjected his patients to unsupervised trips - certainly not over the course of two months when her hospital records show she was given LSD 14 times. "It was terrifying," Mrs. Orlikow recalls. "You're afraid you've gone off somewhere and can't come back." She was supposed to write down on a pad whatever came into her head while listening to the tapes, but often she became so frightened that she could not write at all. "You become very small," she says, as her voice quickens and starts to reflect some of her horror. "You're going to fall off the step, and God, you're going down into hell because it's so far, and you are so little. Like Alice, where is the pill that makes you big, and you're a squirrel, and you can't get out of the cage, and somebody's going to kill you." Then, suddenly, Mrs. Orlikow pulls out of it and lucidly states, "Some very weird things happened."

Mrs. Orlikow hated the LSD treatment. Several times she told Cameron she would take no more, and the psychiatrist would put his arm around her and ask, "Lassie," which he called all his women patients, "don't you want to get well, so you can go home and see your husband?" She remembers feeling guilty about not following the doctor's orders, and the thought of disappointing Cameron, whom she idolized, crushed her. Finally, after Cameron talked her out of quitting the treatment several times, she had to end it. She left the hospital but stayed under his private care. In 1963 he put her back in the hospital for more intensive psychic driving. "I thought he was God," she states. "I don't know how I could have been so stupid.... A lot of us were naive. We thought psychiatrists had the answers. Here was the greatest in the world, with all these titles."

In defense of Cameron, a former associate says the man truly cared about the welfare of his patients. He wanted to make them well. As his former staff psychologist wrote:

> He abhorred the waste of human potential, seen most dramatically in the young people whose minds were distorted by what was then considered to be schizophrenia. He felt equally strongly about the loss of wisdom in the aged through memory malfunction. For him, the end justified the means, and when one is dealing with the waste of human potential, it is easy to adopt this stance.

Cameron retired abruptly in 1964, for unexplained reasons. His successor, Dr. Robert Cleghorn, made a virtually unprecedented move in the academic world of mutual back-scratching and praise. He commissioned a psychiatrist and a psychologist, unconnected to Cameron, to study his electroshock work. They found that 60 percent of Cameron's depatterned patients complained they still had amnesia for the period 6 months to 10 years before the therapy.[6] They could find no clinical proof that showed the treatment to be any more or less effective than other approaches. They concluded that "the incidence of physical complications and the anxiety generated in the patient because of real or imagined memory difficulty argue against" future use of the technique.

The study-team members couched their report in densely academic jargon, but one of them speaks more clearly now. He talks bitterly of one of Cameron's former patients who needs to keep a list of her simplest household chores to remember how to do them. Then he repeats several times how powerful a man Cameron was, how he was "the godfather of Canadian psychiatry." He continues, "I probably shouldn't talk about this, but Cameron - for him to do what he did - he was a very schizophrenic guy, who totally detached himself from the human implications of his work ... God, we talk about concentration camps. I don't want to make this comparison, but God, you talk about 'we didn't know it was happening,' and it was - right in our back yard."

Cameron died in 1967, at age 66, while climbing a mountain. The American Journal of Psychiatry published a long and glowing obituary with a full-page picture of his not-unpleasant face.

D. Ewen Cameron did not need the CIA to corrupt him. He clearly had his mind set on doing unorthodox research long before the Agency front started to fund him. With his own hospital and source of subjects, he could have found elsewhere encouragement and money to replace the CIA's contribution which never exceeded $20,000 a year. However, Agency officials knew exactly what they were paying for. They traveled periodically to Montreal to observe his work, and his proposal was chillingly explicit. In Cameron, they had a doctor, conveniently outside the United States, willing to do terminal experiments in electroshock, sensory deprivation, drug testing, and all of the above combined. By literally wiping the minds of his subjects clean by depatterning and then trying to program in new behavior, Cameron carried the process known as "brainwashing" to its logical extreme.

It cannot be said how many - if any - other Agency brainwashing projects reached the extremes of Cameron's work. Details are scarce, since many of the principal witnesses have died, will not talk about what went on, or lie about it. In what ways the CIA applied work like Cameron's is not known. What is known, however, is that the intelligence community, including the CIA, changed the face of the scientific community during the 1950s and early 1960s by its interest in such experiments. Nearly every scientist on the frontiers of brain research found men from the secret agencies looking over his shoulders, impinging on the research. The experience of Dr. John Lilly illustrates how this intrusion came about.

In 1953 Lilly worked at the National Institutes of Health, outside Washington, doing experimental studies in an effort to "map" the body functions controlled from various locations in the brain. He devised a method of pounding up to 600 tiny sections of hypodermic tubing into the skulls of monkeys, through which he could insert electrodes "into the brain to any desired distance and at any desired location from the cortex down to the bottom of the skull," he later wrote. Using electric stimulation, Lilly discovered precise centers of the monkeys' brains that caused pain, fear, anxiety, and anger. He also discovered precise, separate parts of the brain that controlled erection, ejaculation, and orgasm in male monkeys. Lilly found that a monkey, given access to a switch operating a correctly planted electrode, would reward himself with nearly continuous orgasms - at least once every 3 minutes - for up to 16 hours a day.

As Lilly refined his brain "maps," officials of the CIA and other agencies descended upon him with a request for a briefing. Having a phobia against secrecy, Lilly agreed to the briefing only under the condition that it and his work remain unclassified, completely open to outsiders. The intelligence officials submitted to the conditions most reluctantly, since they knew that Lilly's openness would not only ruin the spy value of anything they learned but could also reveal the identities and the interests of the intelligence officials to enemy agents. They considered Lilly annoying, uncooperative - possibly even suspicious.

Soon Lilly began to have trouble going to meetings and conferences with his colleagues. As part of the cooperation with the intelligence agencies, most of them had agreed to have their projects officially classified as SECRET, which meant that access to the information required a security clearance.[7] Lilly's security clearance was withdrawn for review, then tangled up and misplaced - all of which he took as pressure to cooperate with the CIA. Lilly, whose imagination needed no stimulation to conjure up pictures of CIA agents on deadly missions with remote-controlled electrodes strategically implanted in their brains, decided to withdraw from that field of research. He says he had decided that the physical intrusion of the electrodes did too much brain damage for him to tolerate.

In 1954 Lilly began trying to isolate the operations of the brain, free of outside stimulation, through sensory deprivation. He worked in an office next to Dr. Maitland Baldwin, who the following year agreed to perform terminal sensory deprivation experiments for ARTICHOKE's Morse Allen but who never told Lilly he was working in the field. While Baldwin experimented with his sensory-deprivation "box," Lilly invented a special "tank." Subjects floated in a tank of body-temperature water wearing a face mask that provided air but cut off sight and sound. Inevitably, intelligence officials swooped down on Lilly again, interested in the use of his tank as an interrogation tool. Could involuntary subjects be placed in the tank and broken down to the point where their belief systems or personalities could be altered?

It was central to Lilly's ethic that he himself be the first subject of any experiment, and, in the case of the consciousness-exploring tank work, he and one colleague were the only ones. Lilly realized that the intelligence agencies were not interested in sensory deprivation because of its positive benefits, and he finally concluded that it was impossible for him to work at the National Institutes of Health without compromising his principles. He quit in 1958.

Contrary to most people's intuitive expectations, Lilly found sensory deprivation to be a profoundly integrating experience for himself personally. He considered himself to be a scientist who subjectively explored the far wanderings of the brain. In a series of private experiments, he pushed himself into the complete unknown by injecting pure Sandoz LSD into his thigh before climbing into the sensory-deprivation tank.[8] When the counterculture sprang up, Lilly became something of a cult figure, with his unique approach to scientific inquiry - though he was considered more of an outcast by many in the professional research community.

For most of the outside world, Lilly became famous with the release of the popular film, The Day of the Dolphin, which the filmmakers acknowledged was based on Lilly's work with dolphins after he left NIH. Actor George C. Scott portrayed a scientist, who, like Lilly, loved dolphins, did pioneering experiments on their intelligence, and tried to find ways to communicate with them. In the movie, Scott became dismayed when the government pounced on his breakthrough in talking to dolphins and turned it immediately to the service of war. In real life, Lilly was similarly dismayed when Navy and CIA scientists trained dolphins for special warfare in the waters off Vietnam.[9]

A few scientists like Lilly made up their minds not to cross certain ethical lines in their experimental work, while others were prepared to go further even than their sponsors from ARTICHOKE and MKULTRA. Within the Agency itself, there was only one final question: Will a technique work? CIA officials zealously tracked every lead, sparing no expense to check each angle many times over.

By the time the MKULTRA program ended in 1963, Agency researchers had found no foolproof way to brainwash another person.[10] "All experiments beyond a certain point always failed," says the MKULTRA veteran, "because the subject jerked himself back for some reason or the subject got amnesiac or catatonic." Agency officials found through work like Cameron's that they could create "vegetables," but such people served no operational use. People could be tortured into saying anything, but no science could guarantee that they would tell the truth.

The impotency of brainwashing techniques left the Agency in a difficult spot when Yuri Nosenko defected to the United States in February 1964. A ranking official of the Soviet KGB, Nosenko brought with him stunning information. He said the Russians had bugged the American embassy in Moscow, which turned out to be true.

He named some Russian agents in the West. And he said that he had personally inspected the KGB file of Lee Harvey Oswald, who only a few months earlier had been murdered before he could be brought to trial for the assassination of President Kennedy. Nosenko said he learned that the KGB had had no interest in Oswald.

Was Nosenko telling the truth, or was he a KGB "plant" sent to throw the United States off track about Oswald? Was his information about penetration correct, or was Nosenko himself the penetration? Was he acting in good faith? Were the men within the CIA who believed he was acting in good faith themselves acting in good faith? These and a thousand other questions made up the classical trick deck for spies - each card having "true" on one side and "false" on the other.

Top CIA officials felt a desperate need to resolve the issue of Nosenko's legitimacy. With numerous Agency counterintelligence operations hanging in the balance, Richard Helms, first as Deputy Director and then as Director, allowed CIA operators to work Nosenko over with the interrogation method in which Helms apparently had the most faith. It turned out to be not any truth serum or electroshock depatterning program or anything else from the Agency's brainwashing search. Helms had Nosenko put through the tried-and-true Soviet method: isolate the prisoner, deaden his senses, break him. For more than three years - 1,277 days, to be exact - Agency officers kept Nosenko in solitary confinement. As if they were using the Hinkle-Wolff study as their instruction manual and the Cardinal Mindszenty case as their success story, the CIA men had guards watch over Nosenko day and night, giving him not a moment of privacy. A light bulb burned continuously in his cell. He was allowed nothing to read - not even the labels on toothpaste boxes. When he tried to distract himself by making a chess set from pieces of lint in his cell, the guards discovered his game and swept the area clean. Nosenko had no window, and he was eventually put in a specially built 12' X 12' steel bank vault.

Nosenko broke down. He hallucinated. He talked his head off to his interrogators, who questioned him for 292 days, often while they had him strapped into a lie detector. If he told the truth, they did not believe him. While the Soviets and Chinese had shown that they could make a man admit anything, the CIA interrogators apparently lacked a clear idea of exactly what they wanted Nosenko to confess. When it was all over and Richard Helms ordered Nosenko freed after three and a half years of illegal detention, some key Agency officers still believed he was a KGB plant. Others thought he was on the level. Thus the big questions remained unresolved, and to this day, CIA men - past and present - are bitterly split over who Nosenko really is.

With the Nosenko case, the CIA's brainwashing programs had come full circle. Spurred by the widespread alarm over communist tactics, Agency officials had investigated the field, started their own projects, and looked to the latest technology to make improvements. After 10 years of research, with some rather gruesome results, CIA officials had come up with no techniques on which they felt they could rely. Thus, when the operational crunch came, they fell back on the basic brutality of the Soviet system.

Notes 8

Edward Hunter's article " 'Brain-Washing' Tactics Force Chinese into Ranks of Communist Party" appeared in the Miami News on September 24, 1950. His book was Brainwashing in Red China (New York: Vanguard Press, 1951). Other material came from several interviews with Hunter just before he died in June 1978.

The Air Force document cited on brainwashing was called "Air Force Headquarters Panel Convened to Record Air Force Position Regarding Conduct of Personnel in Event of Capture," December 14, 1953. Researcher Sam Zuckerman found it and showed it to me.

The figures on American prisoners in Korea and the quote from Edward Hunter came from hearings before the Senate Permanent Subcommittee on Investigations,84th Congress, June 19,20,26, and 27, 1956.

The material on the setting up of the Cornell-Hinkle-Wolff study came from interviews with Hinkle, Helen Goodell, and several CIA sources. Hinkle's and Wolff's study on brainwashing appeared in classified form on 2 April 1956 as a Technical Services Division publication called Communist Control Techniques and in substantially the same form but unclassified as "Communist Interrogation and Indoctrination of 'Enemies of the State' - An Analysis of Methods Used by the Communist State Police." AMA Archives of Neurology and Psychiatry, August, 1956, Vol. 76.

Allen Dulles spoke on "Brain Warfare" before the Alumni Conference of Princeton University, Hot Springs, Virginia on April 10, 1953, and the quote on guinea pigs came from that speech.

The comments of Rockefeller Foundation officials about D. Ewen Cameron and the record of Rockefeller funding were found in Robert S. Morrison's diary, located in the Rockefeller Foundation Archives, Pocantico Hills, New York.

The key articles on Cameron's work on depatterning and psychic driving were "Production of Differential Amnesia as a Factor in the Treatment of Schizophrenia," Comprehensive Psychiatry, 1960, 1, p. 26 and "Effects of Repetition of Verbal Signals upon the Behavior of Chronic Psychoneurotic Patients" by Cameron, Leonard Levy, and Leonard Rubenstein, Journal of Mental Science, 1960, 106, 742. The background on Page-Russell electroshocks came from "Intensified Electrical Convulsive Therapy in the Treatment of Mental Disorders" by L. G. M. Page and R. J. Russell, Lancet, Volume 254, Jan. - June, 1948. Dr. John Cavanagh of Washington, D.C. provided background on the use of electroshock and sedatives in psychiatry.

Cameron's MKULTRA subproject was #68. See especially document 68-37, "Application for Grant to Study the Effects upon Human Behavior of the Repetition of Verbal Signals," January 21, 1957.

Part of Cameron's papers are in the archives of the American Psychiatric Association in Washington, and they provided considerable information on the treatment of Mary C., as well as a general look at his work. Interviews with at least a dozen of his former colleagues also provided considerable information.

Interviews Yvith John Lilly and Donald Hebb provided background on sensory deprivation. Maitland Baldwin's work in the field was discussed in a whole series of ARTICHOKE documents including #A/B, I,76/4, 21 March 1955, Subject: Total Isolation; #A/B,1, 76/12, 19 May 1955, Subject: Total Isolation - Additional Comments; and #A/B, I, 76/17,27 April 1955, Subject: Total Isolation, Supplemental Report #2. The quote from Aldous Huxley on sensory deprivation is taken from the book of his writings, Moksha: Writings on Psychedelics and the Visionary Experience (1931-1963), edited by Michael Horowitz and Cynthia Palmer (New York: Stonehill, 1978).

The material on Val Orlikow's experiences with Dr. Cameron came from interviews with her and her husband David and from portions of her hospital records, which she furnished.

Cameron's staff psychologist Barbara Winrib's comments on him were found in a letter to the Montreal Star, August 11, 1977.

The study of Cameron's electroshock work ordered by Dr. Cleghorn was published as "Intensive Electroconvulsive Therapy: A Follow-up Study," by A. E. Schwartzman and P. E. Termansen, Canadian Psychiatric Association, Volume 12, 1967.

In addition to several interviews, much material on John Lilly came from his autobiography, The Scientist (Philadelphia: J. B. Lippincott Company, 1978).

The CIA's handling of Yuri Nosenko was discussed at length in hearings before the House Assassinations Committee on September 15, 1978. The best press account of this testimony was written by Jeremiah O'Leary of the Washington Star on September 16, 1978: "How CIA Tried to Break Defector in Oswald Case."

Footnotes 8

1. Among the Air Force and Army project leaders were Dr. Fred Williams of the Air Force Psychological Warfare Division, Robert Jay Lifton, Edgar Schein, Albert Biderman, and Lieutenant Colonel James Monroe (an Air Force officer who would later go to work full time in CIA behavioral programs).
2. Cameron himself may not have known that the Agency was the ultimate source of these funds which came through a conduit, the Society for the Investigation of Human Ecology. A CIA document stated he was unwitting when the grants started in 1957, and it cannot be said whether he ever found out.
3. Cameron wrote that when a patient remembered his schizophrenic symptoms, the schizophrenic behavior usually returned. If the amnesia held for these symptoms, as Cameron claimed it often did, the subject usually did not have a relapse. Even in his "cured" patients, Cameron found that Rorschach tests continued to show schizophrenic thinking despite the improvement in overt behavior. To a layman, this would seem to indicate that Cameron's approach got only at the symptoms, not the causes of

mental problems. Not deterred, however, Cameron dismissed this inconsistency as a "persistent enigma."

4. Cameron wrote in a professional journal that he gave only two electroshocks a day, but a doctor who actually administered the treatment for him says that three were common at the beginning of the therapy.
5. In his proposal to the Human Ecology group, Cameron wrote that his subjects would be spending only 16 hours a day in sensory deprivation, while they listened to psychic driving tapes (thus providing some outside stimuli). Nevertheless, one of Cameron's colleagues states that some patients, including Mary C. were in continuously. Always looking for a better way, Cameron almost certainly tried both variations.
6. Cleghorn's team found little loss of memory on objective tests, like the Wechsler Memory Scale but speculated that these tests measured a different memory function - short-term recall - than that the subjects claimed to be missing.
7. Lilly and other veterans of government-supported research note that there is a practical advantage for the scientist who allows his work to be classified: it gives him an added claim on government funds. He is then in a position to argue that if his work is important enough to be SECRET, it deserves money.
8. As was the case with LSD work, sensory deprivation research had both a mind control and a transcendental side. Aldous Huxley wrote thusly about the two pioneers in the field: "What men like Hebb and Lilly are doing in the laboratory was done by the Christian hermits in the Thebaid and elsewhere, and by Hindu and Tibetan hermits in the remote fastness of the Himalayas. My own belief is that these experiences really tell us something about the nature of the universe, that they are valuable in themselves and, above all, valuable when incorporated into our world-picture and acted upon [in] normal life."
9. In a program called "swimmer nullification," government scientists trained dolphins to attack enemy frogmen with huge needles attached to their snouts. The dolphins carried tanks of compressed air, which when jabbed into a deepdiver caused him to pop dead to the surface. A scientist who worked in this CIA-Navy program states that some of the dolphins sent to Vietnam during the late 1960s got out of their pens and disappeared - unheard of behavior for trained dolphins. John Lilly confirms that a group of the marine mammals stationed at Cam Ranh Bay did go AWOL, and he adds that he heard that some eventually returned with their bodies and fins covered with attack marks made by other dolphins.
10. After 1963 the Agency's Science and Technology Directorate continued brain research with unknown results. See Chapter 12.

9. Human Ecology

Well before Harold Wolff and Lawrence Hinkle finished their brainwashing study for Allen Dulles in 1956, Wolff was trying to expand his role in CIA research and operations. He offered Agency officials the cooperation of his colleagues at Cornell University, where he taught neurology and psychiatry in the Medical College. In proposal after proposal, Wolff pressed upon the CIA his idea that to understand human behavior - and how governments might manipulate it - one had to study man in relationship to his total environment. Calling this field "human ecology," Wolff drew into it the disciplines of psychology, medicine, sociology, and anthropology. In the academic world of the early 1950s, this cross-disciplinary approach was somewhat new, as was the word "ecology," but it made sense to CIA officials. Like Wolff, they were far in advance of the trends in the behavioral sciences.

Wolff carved out vast tracts of human knowledge, some only freshly discovered, and proposed a partnership with the Agency for the task of mastering that knowledge for operational use. It was a time when knowledge itself seemed bountiful and promising, and Wolff was expansive about how the CIA could harness it. Once he figured out how the human mind really worked, he wrote, he would tell the Agency "how a man can be made to think, 'feel,' and behave according to the wishes of other men, and, conversely, how a man can avoid being influenced in this manner."

Such notions, which may now appear naive or perverse, did not seem so unlikely at the height of the Cold War. And Wolff's professional stature added weight to his ideas. Like D. Ewen Cameron, he was no obscure academic. He had been President of the New York Neurological Association and would become, in 1960, President of the American Neurological Association. He served for several years as editor-in-chief of the American Medical Association's Archives of Neurology and Psychiatry. Both by credentials and force of personality, Wolff was an impressive figure. CIA officials listened respectfully to his grand vision of how spies and doctors could work symbiotically to help - if not save - the world. Also, the Agency men never forgot that Wolff had become close to Director Allen Dulles while treating Dulles' son for brain damage.

Wolff's specialized neurological practice led him to believe that brain maladies, like migraine headaches, occurred because of disharmony between man and his environment. In this case, he wrote to the Agency, "The problem faced by the physician is quite similar to that faced by the Communist interrogator." Both would be trying to put their subject back in harmony with his environment whether the problem was headache or ideological dissent. Wolff believed that the beneficial effects of any new interrogation technique would naturally spill over into the treatment of his patients, and vice versa. Following the Soviet model, he felt he could help his patients by putting them into an isolated, disoriented state - from which it would be easier to create new behavior patterns. Although Russian-style isolation cells were impractical at Cornell, Wolff hoped to get the same effect more quickly through sensory deprivation. He told the Agency that sensory-deprivation chambers had "valid medical reason" as part of a treatment that relieved migraine symptoms and made the patient "more receptive to the suggestions of the psychotherapist." He proposed keeping his patients in sensory deprivation until they "show an increased desire to talk and to escape from the procedure." Then, he said, doctors could "utilize material from their own past experience in order to create psychological reactions within them." This procedure drew heavily on the Stalinist method. It cannot be said what success, if any, Wolff had with it to the benefit of his patients at Cornell.

Wolff offered to devise ways to use the broadest cultural and social processes in human ecology for covert operations. He understood that every country had unique customs for child rearing, military training, and nearly every other form of human intercourse. From the CIA's point of view, he noted, this kind of sociological information could be applied mainly to indoctrinating and motivating people. He distinguished these motivating techniques from the "special methods" that he felt were 'more relevant to subversion, seduction, and interrogation." He offered to study those methods, too, and asked the Agency to give him access to everything in its files on "threats, coercion, imprisonment, isolation, deprivation, humiliation, torture, 'brainwashing, "black psychiatry,' hypnosis, and combinations of these with or without chemical agents." Beyond mere study, Wolff volunteered the unwitting use of Cornell patients for brainwashing experiments, so long as no one got hurt. He added, however, that he would advise the CIA on experiments that harmed their subjects if they were performed elsewhere. He obviously felt that only the grandest sweep of knowledge, flowing freely between scholar and spy, could bring the best available techniques to bear on their respective subjects.

In 1955 Wolff incorporated his CIA-funded study group as the Society for the Investigation of Human Ecology, with himself as president.[1] Through the Society, Wolff extended his efforts for the Agency, and his organization turned into a CIA-controlled funding mechanism for studies and experiments in the behavioral sciences.

In the early days of the Society, Agency officials trusted Wolff and his untried ideas with a sensitive espionage assignment. In effect, the new specialty of human ecology was going to telescope the stages of research and application into one continuing process. Speeding up the traditional academic method was required because the CIA men faced an urgent problem. "What was bothering them," Lawrence Hinkle explains, "was that the Chinese had cleaned up their agents in China.... What they really wanted to do was come up with some Chinese [in America], steer them to us, and make them into agents." Wolff accepted the challenge and suggested that the Cornell group hide its real purpose behind the cover of investigating "the ecological aspects of disease" among Chinese refugees. The Agency gave the project a budget of $84,175 (about 30 percent of the money it put into Cornell in 1955) and supplied the study group with 100 Chinese refugees to work with. Nearly all these subjects had been studying in the United States when the communists took over the mainland in 1949, so they tended to be dislocated people in their thirties.

On the Agency side, the main concern, as expressed by one ARTICHOKE man, was the "security hazard" of bringing together so many potential agents in one place. Nevertheless, CIA officials decided to go ahead. Wolff promised to tell them about the inner reaches of the Chinese character, and they recognized the operational advantage that insight into Chinese behavior patterns could provide. Moreover, Wolff said he would pick out the most useful possible agents. The Human Ecology Society would then offer these candidates "fellowships" and subject them to more intensive interviews and "stress producing" situations. The idea was to find out about their personalities, past conditioning, and present motivations, in order to figure out how they might perform in future predicaments - such as finding themselves back in Mainland China as American agents. In the process, Wolff hoped to mold these Chinese into people willing to work for the CIA. Mindful of leaving some cover for Cornell, he was adamant that Agency operators not connected with the project make the actual recruitment pitch to those Chinese whom the Agency men wanted as agents.

As a final twist, Wolff planned to provide each agent with techniques to withstand the precise forms of hostile interrogation they could expect upon returning to China. CIA officials wanted to "precondition" the agents in order to create long lasting motivation "impervious to lapse of time and direct psychological attacks by the enemy." In other words, Agency men planned to brainwash their agents in order to protect them against Chinese brainwashing.

Everything was covered - in theory, at least. Wolff was going to take a crew of 100 refugees and turn as many of them as possible into detection-proof, live agents inside China, and he planned to do the job quickly through human ecology. It was a heady chore for the Cornell professor to take on after classes.

Wolff hired a full complement of psychologists, psychiatrists, and anthropologists to work on the project. He bulldozed his way through his colleagues' qualms and government red tape alike. Having hired an anthropologist before learning that the CIA security office would not give her a clearance, Wolff simply lied to her about where the money came from. "It was a function of Wolff's imperious nature," says his partner Hinkle. "If a dog came in and threw up on the rug during a lecture, he would continue." Even the CIA men soon found that Harold Wolff was not to be trifled with. "From the Agency side, I don't know anyone who wasn't scared of him," recalls a longtime CIA associate. "He was an autocratic man. I never knew him to chew anyone out. He didn't have to. We were damned respectful. He moved in high places. He was just a skinny little man but talk about mind control! He was one of the controllers."

In the name of the Human Ecology Society, the CIA paid $1,200 a month to rent a fancy town house on Manhattan's East 78th Street to house the Cornell group and its research projects Agency technicians traveled to New York in December 1954 to install eavesdropping microphones around the building. These and other more obvious security devices - safes, guards, and the like - made the town house look different from the academic center it was supposed to be. CIA liaison personnel held meetings with Wolff and the staff in the secure confines of the town house, and they all carefully watched the 100 Chinese a few blocks away at the Cornell hospital. The Society paid each subject $25 a day so the researchers could test them, probe them, and generally learn all they could about Chinese people - or at least about middle-class, displaced, anti-Communist ones.

It is doubtful that any of Wolff's Chinese ever returned to their homeland as CIA agents, or that all of Wolff's proposals were put into effect. In any case, the project was interrupted in midstream by a major shake-up in the CIA's entire mind-control effort. Early in 1955, Sid Gottlieb and his Ph.D. crew from TSS took over most of the ARTICHOKE functions, including the Society, from Morse Allen and the Pinkerton types in the Office of Security. The MKULTRA men moved quickly to turn the Society into an entity that looked and acted like a legitimate foundation. First they smoothed over the ragged covert edges. Out came the bugs and safes so dear to Morse Allen and company. The new crew even made some effort (largely unsuccessful) to attract non-CIA funds. The biggest change, however, was the Cornell professors now had to deal with Agency representatives who were scientists and who had strong ideas of their own on research questions. Up to this point, the Cornellians had been able to keep the CIA's involvement within bounds acceptable to them. While Harold Wolff never ceased wanting to explore the furthest reaches of behavior control, his colleagues were wary of going on to the outer limits - at least under Cornell cover.

No one would ever confuse MKULTRA projects with ivory-tower research, but Gottlieb's people did take a more academic - and sophisticated - approach to behavioral research than their predecessors. The MKULTRA men understood that not every project would have an immediate operational benefit, and they believed less and less in the existence of that one just-over-the-horizon technique that would turn men into puppets. They favored increasing their knowledge of human behavior in relatively small steps, and they concentrated on the reduced goal of influencing and manipulating their subjects. "You're ahead of the game if you can get people to do something ten percent more often than they would otherwise," says an MKULTRA veteran.

Accordingly, in 1956, Sid Gottlieb approved a $74,000 project to have the Human Ecology Society study the factors that caused men to defect from their countries and cooperate with foreign governments. MKULTRA officials reasoned that if they could understand what made old turncoats tick, it might help them entice new ones. While good case officers instinctively seemed to know how to handle a potential agent - or thought they did - the MKULTRA men hoped to come up with systematic, even scientific improvements. Overtly, Harold Wolff designed the program to look like a follow-up study to the Society's earlier programs, noting to the Agency that it was "feasible to study foreign nationals under the cover of a medical-sociological study." (He told his CIA founders that "while some information of general value to science should be produced, this in itself will not be a sufficient justification for carrying out a study of this nature.") Covertly, he declared the purpose of the research was to assess defectors' social and cultural background, their life experience, and their personality structure, in order to understand their motivations, value systems, and probable future reactions.

The 1956 Hungarian revolt occurred as the defector study was getting underway, and the Human Ecology group, with CIA headquarters approval, decided to turn the defector work into an investigation of 70 Hungarian refugees from that upheaval. By then, most of Harold Wolff's team had been together through the brainwashing and Chinese studies. While not all of them knew of the CIA's specific interests, they had streamlined their procedures for answering the questions that Agency officials found interesting. They ran the Hungarians through the battery of tests and observations in six months, compared to a year and a half for the Chinese project.

The Human Ecology Society reported that most of their Hungarian subjects had fought against the Russians during the Revolution and that they had lived through extraordinarily difficult circumstances, including arrest, mistreatment, and indoctrination. The psychologists and psychiatrists found that, often, those who had survived with the fewest problems had been those with markedly aberrant personalities. "This observation has added to the evidence that healthy people are not necessarily 'normal,' but are people particularly adapted to their special life situations," the group declared.

While CIA officials liked the idea that their Hungarian subjects had not knuckled under communist influence, they recognized that they were working with a skewed sample. American visa restrictions kept most of the refugee left-wingers and former communist officials out of the United States; so, as a later MKULTRA document would state, the Society wound up studying "western-tied rightist elements who had never been accepted completely" in postwar Hungary. Agency researchers realized that these people would "contribute little" toward increasing the CIA's knowledge of the processes that made a communist official change his loyalties.

In order to broaden their data base, MKULTRA officials decided in March 1957 to bring in some unwitting help. They gave a contract to Rutgers University sociologists Richard Stephenson and Jay Schulman "to throw as much light as possible on the sociology of the communist system in the throes of revolution." The Rutgers professors started out by interviewing the 70 Hungarians at Cornell in New York, and Schulman went on to Europe to talk to disillusioned Communists who had also fled their country. From an operational point of view, these were the people the Agency really cared about; but, as socialists, most of them probably would have resisted sharing their experiences with the CIA - if they had known.[2]

Jay Schulman would have resisted, too. After discovering almost 20 years later that the Agency had paid his way and seen his confidential interviews, he feels misused. "In 1957 I was myself a quasi-Marxist and if I had known that this study was sponsored by the CIA, there is really, obviously, no way that I would have been associated with it," says Schulman. "My view is that social scientists have a deep personal responsibility for questioning the sources of funding; and the fact that I didn't do it at the time was simply, in my judgment, indication of my own naiveté and political innocence, in spite of my ideological bent."

Deceiving Schulman and his Hungarian subjects did not bother the men from MKULTRA in the slightest. According to a Gottlieb aide, one of the strong arguments inside the CIA for the whole Human Ecology program was that it gave the Agency a means of approaching and using political mavericks who could not otherwise get security clearances. "Sometimes," he chuckles, "these left-wing social scientists were damned good." This MKULTRA veteran scoffs at the displeasure Schulman expresses: "If we'd gone to a guy and said, 'We're CIA,' he never would have done it. They were glad to get the money in a world where damned few people were willing to support them.... They can't complain about how they were treated or that they were asked to do something they wouldn't have normally done."

The Human Ecology Society soon became a conduit for CIA money flowing to projects, like the Rutgers one, outside Cornell. For these grants, the Society provided only cover and administrative support behind the gold-plated names of Cornell and Harold Wolff. From 1955 to 1958, Agency officials passed funds through the Society for work on criminal sexual psychopaths at Ionia State Hospital,[3] a mental institution located on the banks of the Grand River in the rolling farm country 120 miles northwest of Detroit. This project had an interesting hypothesis: That child molesters and rapists had ugly secrets buried deep within them and that their stake in not admitting their perversions approached that of spies not wanting to confess. The MKULTRA men reasoned that any technique that would work on a sexual psychopath would surely have a similar effect on a foreign agent. Using psychologists and psychiatrists connected to the Michigan mental health and the Detroit court systems, they set up a program to test LSD and marijuana, wittingly and unwittingly, alone and in combination with hypnosis. Because of administrative delays, the Michigan doctors managed to experiment only on 26 inmates in three years - all sexual offenders committed by judges without a trial under a Michigan law, since declared unconstitutional. The search for a truth drug went on, under the auspices of the Human Ecology Society, as well as in other MKULTRA channels.

The Ionia project was the kind of expansionist activity that made Cornell administrators, if not Harold Wolff, uneasy. By 1957, the Cornellians had had enough. At the same time, the Agency sponsors decided that the Society had outgrown its dependence on Cornell for academic credentials - that in fact the close ties to Cornell might inhibit the Society's future growth among academics notoriously sensitive to institutional conflicts. One CIA official wrote that the Society "must be given more established stature in the research community to be effective as a cover organization." Once the Society was cut loose in the foundation world, Agency men felt they would be freer to go anywhere in academia to buy research that might assist covert operations. So the CIA severed the Society's formal connection to Cornell.

The Human Ecology group moved out of its East 78th Street town house, which had always seem a little too plush for a university program, and opened up a new headquarters in Forest Hills, Queens, which was an inappropriate neighborhood for a well-connected foundation.[4] Agency officials hired a staff of four led by Lieutenant Colonel James Monroe, who had worked closely with the CIA as head of the Air Force's study of Korean War prisoners. Sid Gottlieb and the TSS hierarchy in Washington still made the major decisions, but Monroe and the Society staff, whose salaries the Agency paid, took over the Society's dealings with the outside world and the monitoring of several hundred thousand dollars a year in research projects. Monroe personally supervised dozens of grants, including Dr. Ewen Cameron's brainwashing work in Montreal. Soon the Society was flourishing as an innovative foundation, attracting research proposals from a wide variety of behavioral scientists, at a time when these people - particularly the unorthodox ones - were still the stepchildren of the fund-granting world.

After the Society's exit from Cornell, Wolff and Hinkle stayed on as president and vice-president, respectively, of the Society's board of directors. Dr. Joseph Hinsey, head of the New York Hospital-Cornell Medical Center also remained on the board. Allen Dulles continued his personal interest in the Society's work and came to one of the first meetings of the new board, which, as was customary with CIA fronts, included some big outside names. These luminaries added worthiness to the enterprise while playing essentially figurehead roles. In 1957 the other board members were John Whitehorn, chairman of the psychiatry department at Johns Hopkins University, Carl Rogers, professor of psychology and psychiatry at the University of Wisconsin, and Adolf A. Berle, onetime Assistant Secretary of State and chairman of the New York Liberal Party.[5] Berle had originally put his close friend Harold Wolff in touch with the CIA, and at Wolff's request, he came on the Society board despite some reservations. "I am frightened about this one," Berle wrote in his diary. "If the scientists do what they have laid out for themselves, men will become manageable ants. But I don't think it will happen."

There was a lot of old-fashioned backscratching among the CIA people and the academics as they settled into the work of accommodating each other. Even Harold Wolff, the first and the most enthusiastic of the scholar-spies, had made it clear from the beginning that he expected some practical rewards for his service. According to colleague Hinkle, who appreciated Wolff as one the great grantsman of his time, Wolff expected that the Agency "would support our research and we would be their consultants." Wolff bluntly informed the CIA that some of his work would have no direct use "except that it vastly enhances our value ... as consultants and advisers." In other words, Wolff felt that his worth to the CIA increased in proportion to his professional accomplishments and importance - which in turn depended partly on the resources he commanded. The Agency men understood, and over the last half of the 1950s, they were happy to contribute almost $300,000 to Wolff's own research on the brain and central nervous system. In turn, Wolff and his reputation helped them gain access to other leading lights in the academic world.

Another person who benefited from Human Ecology funds was Carl Rogers, whom Wolff had also asked to serve on the board. Rogers, who later would become famous for his nondirective, nonauthoritarian approach to psychotherapy, respected Wolff's work, and he had no objection to helping the CIA. Although he says he would have nothing to do with secret Agency activities today, he asks for understanding in light of the climate of the 1950s. "We really did regard Russia as the enemy," declares Rogers, "and we were trying to do various things to make sure the Russians did not get the upper hand." Rogers received an important professional reward for joining the Society board. Executive Director James Monroe had let him know that, once he agreed to serve, he could expect to receive a Society grant. "That appealed to me because I was having trouble getting funded," says Rogers. "Having gotten that grant [about $30,000 over three years], it made it possible to get other grants from Rockefeller and NIMH." Rogers still feels grateful to the Society for helping him establish a funding "track record," but he emphasizes that the Agency never had any effect on his research.

Although MKULTRA psychologist John Gittinger suspected that Rogers' work on psychotherapy might provide insight into interrogation methods, the Society did not give Rogers money because of the content of his work. The grant ensured his services as a consultant, if desired, and, according to a CIA document, "free access" to his project. But above all, the grant allowed the Agency to use Rogers' name. His standing in the academic community contributed to the layer of cover around the Society that Agency officials felt was crucial to mask their involvement.

Professor Charles Osgood's status in psychology also improved the Society's cover, but his research was more directly useful to the Agency, and the MKULTRA men paid much more to get it. In 1959 Osgood, who four years later became president of the American Psychological Association, wanted to push forward his work on how people in different societies express the same feelings, even when using different words and concepts. Osgood wrote in "an abstract conceptual framework," but Agency officials saw his research as "directly relevant" to covert activities. They believed they could transfer Osgood's knowledge of "hidden values and cues" in the way people communicate into more effective overseas propaganda. Osgood's work gave them a tool - called the "semantic differential" - to choose the right words in a foreign language to convey a particular meaning.

Like Carl Rogers, Osgood got his first outside funding for what became the most important work of his career from the Human Ecology Society. Osgood had written directly to the CIA for support, and the Society soon contacted him and furnished $192,975 for research over five years. The money allowed him to travel widely and to expand his work into 30 different cultures. Also like Rogers, Osgood eventually received NIMH money to finish his research, but he acknowledges that the Human Ecology grants played an important part in the progress of his work. He stresses that "there was none of the feeling then about the CIA that there is now, in terms of subversive activities," and he states that the Society had no influence on anything he produced. Yet Society men could and did talk to him about his findings. They asked questions that reflected their own covert interests, not his academic pursuits, and they drew him out, according to one of them, "at great length." Osgood had started studying cross-cultural meaning well before he received the Human Ecology money, but the Society's support ensured that he would continue his work on a scale that suited the Agency's purposes, as well as his own.

A whole category of Society funding, called "cover grants," served no other purpose than to build the Society's false front. These included a sociological study of Levittown, Long Island (about $4,500), an analysis of the Central Mongoloid skull ($700), and a look at the foreign-policy attitudes of people who owned fallout shelters, as opposed to people who did not ($2,500). A $500 Human Ecology grant went to Istanbul University for a study of the effects of circumcision on Turkish boys. The researcher found that young Turks, usually circumcised between the ages of five and seven, felt "severe emotional impact with attending symptoms of withdrawal." The children saw the painful operations as "an act of aggression" that brought out previously hidden fears - or so the Human Ecology Society reported.

In other instances, the Society put money into projects whose covert application was so unlikely that only an expert could see the possibilities. Nonetheless, in 1958 the Society gave $5,570 to social psychologists Muzafer and Carolyn Wood Sherif of the University of Oklahoma for work on the behavior of teen-age boys in gangs. The Sherifs, both ignorant of the CIA connection,[6] studied the group structures and attitudes in the gangs and tried to devise ways to channel antisocial behavior into more constructive paths. Their results were filtered through clandestine minds at the Agency. "With gang warfare," says an MKULTRA source, "you tried to get some defectors-in-place who would like to modify some of the group behavior and cool it. Now, getting a juvenile delinquent defector was motivationally not all that much different from getting a Soviet one."

MKULTRA officials were clearly interested in using their grants to build contacts and associations with prestigious academics. The Society put $1,500 a year into the Research in Mental Health Newsletter published jointly at McGill University by the sociology and psychiatric departments. Anthropologist Margaret Mead, an international culture heroine, sat on the newsletter's advisory board (with, among others, D. Ewen Cameron), and the Society used her name in its biennial report. Similarly, the Society gave grants of $26,000 to the well-known University of London psychologist, H. J. Eysenck, for his work on motivation. An MKULTRA document acknowledged that this research would have "no immediate relevance for Agency needs," but that it would "lend prestige" to the Society. The grants to Eysenck also allowed the Society to take funding credit for no less than nine of his publications in its 1963 report. The following year, the Society managed to purchase a piece of the work of the most famous behaviorist of all, Harvard's B. F. Skinner. Skinner, who had tried to train pigeons to guide bombs for the military during World War II, received a $5,000 Human Ecology grant to pay the costs of a secretary and supplies for the research that led to his book, Freedom and Dignity. Skinner has no memory of the grant or its origins but says, "I don't like secret involvement of any kind. I can't see why it couldn't have been open and aboveboard."

A TSS source explains that grants like these "bought legitimacy" for the Society and made the recipients "grateful." He says that the money gave Agency employees at Human Ecology a reason to phone Skinner - or any of the other recipients - to pick his brain about a particular problem. In a similar vein, another MKULTRA man, psychologist John Gittinger mentions the Society's relationship with Erwin Goffman of the University of Pennsylvania, whom many consider today's leading sociological theorist. The Society gave him a small grant to help finish a book that would have been published anyway. As a result, Gittinger was able to spend hours talking with him about, among other things, an article he had written earlier on confidence men. These hucksters were experts at manipulating behavior, according to Gittinger, and Goffman unwittingly "gave us a better understanding of the techniques people use to establish phony relationships" - a subject of interest to the CIA.

To keep track of new developments in the behavioral sciences, Society representatives regularly visited grant recipients and found out what they and their colleagues were doing. Some of the knowing professors became conscious spies. Most simply relayed the latest professional gossip to their visitors and sent along unpublished papers. The prestige of the Human Ecology grantees also helped give the Agency access to behavioral scientists who had no connection to the Society. "You could walk into someone's office and say you were just talking to Skinner," says an MKULTRA veteran. "We didn't hesitate to do this. It was a way to name-drop."

The Society did not limit its intelligence gathering to the United States. As one Agency source puts it, "The Society gave us a legitimate basis to approach anyone in the academic community anywhere in the world." CIA officials regularly used it as cover when they traveled abroad to study the behavior of foreigners of interest to the Agency, including such leaders as Nikita Khrushchev. The Society funded foreign researchers and also gave money to American professors to collect information abroad. In 1960, for instance, the Society sponsored a survey of Soviet psychology through the simple device of putting up $15,000 through the official auspices of the American Psychological Association to send ten prominent psychologists on a tour of the Soviet Union. Nine of the ten had no idea of the Agency involvement, but CIA officials were apparently able to debrief everyone when the group returned. Then the Society sponsored a conference and book for which each psychologist contributed a chapter. The book added another $5,000 to the CIA's cost, but $20,000 all told seemed like a small price to pay for the information gathered. The psychologists - except perhaps the knowledgeable one - did nothing they would not ordinarily have done during their trip, and the scholarly community benefited from increased knowledge on an important subject. The only thing violated was the openness and trust normally associated with academic pursuits. By turning scholars into spies - even unknowing ones - CIA officials risked the reputation of American research work and contributed potential ammunition toward the belief in many countries that the U.S. notion of academic freedom and independence from the state is self-serving and hypocritical.

Secrecy allowed the Agency a measure of freedom from normal academic restrictions and red tape, and the men from MKULTRA used that freedom to make their projects more attractive. The Society demanded "no stupid progress reports," recalls psychologist and psychiatrist Martin Orne, who received a grant to support his Harvard research on hypnotism. As a further sign of generosity and trust, the Society gave Orne a follow-on $30,000 grant with no specified purpose.[7] Orne could use it as he wished. He believes the money was "a contingency investment" in his work, and MKULTRA officials agree. "We could go to Orne anytime," says one of them, "and say, 'Okay, here is a situation and here is a kind of guy. What would you expect we might be able to achieve if we could hypnotize him?' Through his massive knowledge, he could speculate and advise." A handful of other Society grantees also served in similar roles as covert Agency consultants in the field of their expertise.

In general, the Human Ecology Society served as the CIA's window on the world of behavioral research. No phenomenon was too arcane to escape a careful look from the Society, whether extrasensory perception or African witch doctors. "There were some unbelievable schemes," recalls an MKULTRA veteran, "but you also knew Einstein was considered crazy. You couldn't be so biased that you wouldn't leave open the possibility that some crazy idea might work." MKULTRA men realized, according to the veteran, that "ninety percent of what we were doing would fail" to be of any use to the Agency. Yet, with a spirit of inquiry much freer than that usually found in the academic world, the Society took early stabs at cracking the genetic code with computers and finding out whether animals could be controlled through electrodes placed in their brains.

The Society's unrestrained, scattershot approach to behavioral research went against the prevailing wisdom in American universities - both as to methods and to subjects of interest. During the 1950s one school of thought - so-called "behaviorism," - was accepted on campus, virtually to the exclusion of all others. The "behaviorists," led by Harvard's B. F. Skinner, looked at psychology as the study of learned observable responses to outside stimulation. To oversimplify, they championed the approach in which psychologists gave rewards to rats scurrying through mazes, and they tended to dismiss matters of great interest to the Agency: e.g., the effect of drugs on the psyche, subjective phenomena like hypnosis, the inner workings of the mind, and personality theories that took genetic differences into account.

By investing up to $400,000 a year into the early, innovative work of men like Carl Rogers, Charles Osgood, and Martin Orne, the CIA's Human Ecology Society helped liberate the behavioral sciences from the world of rats and cheese. With a push from the Agency as well as other forces, the field opened up. Former iconoclasts became eminent, and, for better or worse, the Skinnerian near-monopoly gave way to a multiplication of contending schools. Eventually, a reputable behavioral scientist could be doing almost anything: holding hands with his students in sensitivity sessions, collecting survey data on spanking habits, or subjectively exploring new modes of consciousness. The CIA's money undoubtedly changed the academic world to some degree, though no one can say how much.

As usual, the CIA men were ahead of their time and had started to move on before the new approaches became established. In 1963, having sampled everything from palm reading to subliminal perception, Sid Gottlieb and his colleagues satisfied themselves that they had overlooked no area of knowledge - however esoteric - that might be promising for CIA operations. The Society had served its purpose; now the money could be better spent elsewhere. Agency officials transferred the still-useful projects to other covert channels and allowed the rest to die quietly. By the end of 1965, when the remaining research was completed, the Society for the Investigation of Human Ecology was gone.

Notes 9

MKULTRA subprojects 48 and 60 provided the basic documents on the Society for the Investigation of Human Ecology. These were supplemented by the three biennial reports of the Society that could be found: 1957, 1961, and 1961-1963. Wolff's own research work is MKULTRA subproject 61. Wolfs proposals to the Agency are in #A/B, II, 10/68, undated "Proposed Plan for Implementing [deleted]" in two documents included in 48-29, March 5, 1956, "General Principles Upon Which these Proposals Are Based." The Agency's plans for the Chinese Project are described in #A/B, II, 10/48, undated, Subject: Cryptonym [deleted] A/B, II 10/72,9 December,1954, Subject: Letter of Instructions, and #A/B, II, 10/110, undated, untitled.

Details of the logistics of renting the Human Ecology headquarters and bugging it are in #A/B, II, 10/23, 30 August, 1954, Subject: Meeting of Working Committee of [deleted], No. 5 and #A/B, II, 10/92, 8 December, 1954, Subject: Technical Installation.

The Hungarian project, as well as being described in the 1957 biennial report, was dealt with in MKULTRA subprojects 65 and 82, especially 65-12, 28 June 1956, Subject: MKULTRA subproject 65; 65-11, undated, Subject: Dr. [deleted]'s Project - Plans for the Coming Year, July,1957-June,1958; and 82-15,11 April 1958, Subject: Project MKULTRA, Subproject 82.

The Ionia State sexual psychopath research was MKULTRA Subproject 39, especially 39-4, 9 April 1958, Subject: Trip Report, Visit to [deleted], 7 April 1958. Paul Magnusson of the Detroit Free Press and David Pearl of the Detroit ACLU office both furnished information.

Carl Rogers' MKULTRA subproject was # 97. He also received funds under Subproject 74. See especially 74-256, 7 October 1958, Supplement to Individual Grant under MKULTRA, Subproject No. 74 and 97-21, 6 August 1959, Subject: MKULTRA Subproject 97.

H. J. Eysenck's MKULTRA subproject was #111. See especially 111-3, 3 April 1961, Subject: Continuation of MKULTRA Subproject 111. The American Psychological Association-sponsored trip to the Soviet Union was described in Subproject 107. The book that came out of the trip was called Some Views on Soviet Psychology, Raymond Bauer (editor), (Washington: American Psychological Association; 1962).

The Sherifs' research on teenage gangs was described in Subproject # 102 and the 1961 Human Ecology biennial report. Dr. Carolyn Sherif also wrote a letter to the American Psychological Association Monitor, February 1978. Dr. Sherif talked about her work when she and I appeared on an August 1978 panel at the American Psychological Association's convention in Toronto.

Martin Orne's work for the Agency was described in Subproject 84. He contributed a chapter to the Society-funded book, The Manipulation of Human Behavior, edited by Albert Biderman and Herbert Zimmer-(New York: John Wiley & Sons; 1961), pp. 169-215. Financial data on Orne's Institute for Experimental Psychiatry came from a filing with the Commonwealth of Massachusetts, Attachment to Form 1023.

The quote from John Gittinger came from an interview with him conducted by Dr. Patricia Greenfield. Dr. Greenfield also interviewed Jay Schulman, Carl Rogers, and Charles Osgood for an article in the December 1977 issue of the American Psychological Association Monitor, from which my quotes of Schulman's comments are taken. She discussed Erving Goffman's role in a presentation to a panel of the American Psychological Association convention in Toronto in August 1978. The talk was titled "CIA Support of Basic Research in Psychology: Policy Implications."

Footnotes 9

1. In 1961 the Society changed its name to the Human Ecology Fund, but for convenience sake it will be called the Society throughout the book.
2. Also to gain access to this same group of leftist Hungarian refugees in Europe, the Human Ecology Society put $15,000 in 1958 into an unwitting study by Dr. A. H. M. Struik of the University of Nijmegen in the Netherlands. An Agency document extolled this arrangement not only as a useful way of studying Hungarians but because it provided "entree" into a leading European university and psychological research center, adding "such a connection has manifold cover and testing possibilities as well as providing a base from which to take advantage of developments in that area of the world."
3. Professor Laurence Hinkle states that it was never his or Cornell's intention that the Society would be used as a CIA funding conduit. When told that he himself had written letters on the Ionia project, he replied that the Society's CIA-supplied bookkeeper was always putting papers in front of him and that he must have signed without realizing the implications.
4. By 1961 the CIA staff had tired of Queens and moved the Society back into Manhattan to 201 East 57th Street. In 1965 as the Agency was closing down the front, it switched its headquarters to 1831 Connecticut Avenue N.W. in Washington, the same building owned by Dr. Charles Geschickter that housed another MKULTRA conduit, the Geschickter Fund for Medical Research.
5. Other establishment figures who would grace the Human Ecology board over the years included Leonard Carmichael, head of the Smithsonian Institution, Barnaby Keeney, president of Brown University, and George A. Kelly, psychology professor and Society fund recipient at Ohio State University.
6. According to Dr. Carolyn Sherif, who says she and her husband did not share the Cold War consensus and would never have knowingly taken CIA funds Human Ecology executive director James Monroe lied directly about the source of the Society's money, claiming it came from rich New York doctors and Texas millionaires who gave it for tax purposes. Monroe used this standard cover story with other grantees.
7. A 1962 report of Orne's laboratory, the Institute for Experimental Psychiatry, showed that it received two sizable grants before the end of that year: $30,000 from Human Ecology and $30,000 from Scientific Engineering Institute, another CIA front organization. Orne says he was not aware of the latter group's Agency connection at the time, but learned of it later. He used its grant to study new ways of using the polygraph.

10. The Gittinger Assessment System

With one exception, the CIA's behavioral research - whether on LSD or on electroshock - seems to have had more impact on the outside world than on Agency operations. That exception grew out of the work of the MKULTRA program's resident genius, psychologist John Gittinger. While on the CIA payroll, toiling to find ways to manipulate people, Gittinger created a unique system for assessing personality and predicting future behavior. He called his method - appropriately - the Personality Assessment System (PAS). Top Agency officials have been so impressed that they have given the Gittinger system a place in most agent-connected activities. To be sure, most CIA operators would not go nearly so far as a former Gittinger aide who says, "The PAS was the key to the whole clandestine business." Still, after most of the touted mind controllers had given up or been sent back home, it was Gittinger, the staff psychologist, who sold his PAS system to cynical, anti-gimmick case officers in the Agency's Clandestine Services. And during the Cuban missile crisis, it was Gittinger who was summoned to the White House to give his advice on how Khrushchev would react to American pressure.

A heavy-set, goateed native of Oklahoma who in his later years came to resemble actor Walter Slezak, Gittinger looked much more like someone's kindly grandfather than a calculating theoretician. He had an almost insatiable curiosity about personality, and he spent most of his waking hours tinkering with and trying to perfect his system. So obsessed did he become that he always had the feeling even after other researchers had verified large chunks of the PAS and after the CIA had put it into operational use - that the whole thing was "a kind of paranoid delusion."

Gittinger started working on his system even before he joined the CIA in 1950. Prior to that, he had been director of psychological services at the state hospital in Norman, Oklahoma. His high-sounding title did not reflect the fact that he was the only psychologist on the staff. A former high school guidance counselor and Naval lieutenant commander during World War II, he was starting out at age 30 with a master's degree. Every day he saw several hundred patients whose mental problems included virtually everything in the clinical textbooks.

Numerous tramps and other itinerants, heading West in search of the good life in California, got stuck in Oklahoma during the cold winter months and managed to get themselves admitted to Gittinger's hospital. In warmer seasons of the year, quite a few of them worked, when they had to, as cooks or dishwashers in the short-order hamburger stands that dotted the highways in the days before fast food. They functioned perfectly well in these jobs until freezing nights drove them from their outdoor beds. The hospital staff usually called them "seasonal schizophrenics" and gave them shelter until spring. Gittinger included them in the psychological tests he was so fond of running on his patients.

As he measured the itinerants on the Wechsler intelligence scale, a standard IQ test with 11 parts,[1] Gittinger made a chance observation that became, he says, the "bedrock" of his whole system. He noticed that the short-order cooks tended to do well on the digit-span subtest which rated their ability to remember numbers. The dishwashers, in contrast, had a poor memory for digits. Since the cooks had to keep track of many complex orders - with countless variations of medium rare, onions, and hold-the-mayo - their retentive quality served them well.

Gittinger also noticed that the cooks had different personality traits than the dishwashers. The cooks seemed able to maintain a high degree of efficiency in a distracting environment while customers were constantly barking new orders at them. They kept their composure by falling back on their internal resources and generally shutting themselves off from the commotion around them. Gittinger dubbed this personality type, which was basically inner-directed, an "Internalizer" (abbreviated "I"). The dishwashers, on the other hand, did not have the ability to separate themselves from the external world. In order to perform their jobs, they had to be placed off in some far corner of the kitchen with their dirty pots and pans, or else all the tumult of the place diverted them from their duty. Gittinger called the dishwasher type an "Externalizer" (E). He found that if he measured a high digit span in any person - not just a short-order cook - he could make a basic judgment about personality.

From observation, Gittinger concluded that babies were born with distinct personalities which then were modified by environmental factors. The Internalized - or I - baby was caught up in himself and tended to be seen as a passive child; hence, the world usually called him a "good baby." The E tot was more interested in outside stimuli and attention, and thus was more likely to cause his parents problems by making demands. Gittinger believed that the way parents and other authority figures reacted to the child helped to shape his personality. Adults often pressured or directed the I child to become more outgoing and the E one to become more self-sufficient. Gittinger found he could measure the compensations, or adjustments, the child made on another Wechsler subtest, the one that rated arithmetic ability. He noticed that in later life, when the person was subject to stress, these compensations tended to disappear, and the person reverted to his original personality type. Gittinger wrote that his system "makes possible the assessment of fundamental discrepancies between the surface personality and the underlying personality structure - discrepancies that produce tension, conflict, and anxiety."

Besides the E-I dimensions, Gittinger identified two other fundamental sets of personality characteristics that he could measure with still other Wechsler subtests. Depending on how a subject did on the block design subtest, Gittinger could tell if he were Regulated (R) or Flexible (F). The Regulated person had no trouble learning by rote but usually did not understand what he learned. The Flexible individual, on the other hand, had to understand something before he learned it. Gittinger noted that R children could learn to play the piano moderately well with comparatively little effort. The F child most often hated the drudgery of piano lessons, but Gittinger observed that the great concert pianists tended to be Fs who had persevered and mastered the instrument.

Other psychologists had thought up personality dimensions similar to Gittinger's E and I, R and F. even if they defined them somewhat differently. Gittinger's most original contribution came in a third personality dimension, which revealed how well people were able to adapt their social behavior to the demands of the culture they lived in. Gittinger found he could measure this dimension with the picture arrangement Wechsler subtest, and he called it the Role Adaptive (A) or Role Uniform (U). It corresponded to "charisma," since other people were naturally attracted to the A person while they tended to ignore the U.

All this became immensely more complicated as Gittinger measured compensations and modifications with other Wechsler subtests. This complexity alone worked against the acceptance of his system by the outside world, as did the fact that he based much of it on ideas that ran contrary to accepted psychological doctrine - such as his heretical notion that genetic differences existed. It did not help, either, that Gittinger was a non-Ph.D. whose theory sprang from the kitchen habits of vagrants in Oklahoma.

Any one of these drawbacks might have stifled Gittinger in the academic world, but to the pragmatists in the CIA, they were irrelevant. Gittinger's strange ideas seemed to work. With uncanny accuracy, he could look at nothing more than a subject's Wechsler numbers, pinpoint his weaknesses, and show how to turn him into an Agency spy. Once Gittinger's boss, Sid Gottlieb, and other high CIA officials realized how Gittinger's PAS could be used to help case officers handle agents, they gave the psychologist both the time and money to improve his system under the auspices of the Human Ecology Society.

Although he was a full-time CIA employee, Gittinger worked under Human Ecology cover through the 1950s. Agency officials considered the PAS to be one of the Society's greatest triumphs, definitely worth continuing after the Society was phased out. In 1962 Gittinger and his co-workers moved their base of operations from the Human Ecology headquarters in New York to a CIA proprietary company, set up especially for them in Washington and called Psychological Assessment Associates. Gittinger served as president of the company, whose cover was to provide psychological services to American firms overseas. He personally opened a branch office in Tokyo (later moved to Hong Kong) to service CIA stations in the Far East. The Washington staff, which grew to about 15 professionals during the 1960s, handled the rest of the world by sending assessment specialists off for temporary visits.

Hundreds of thousands of dollars in Human Ecology grants and then even more money in Psychological Assessment contracts - all CIA funds - flowed out to verify and expand the PAS. For example, the Society gave about $140,000 to David Saunders of the Educational Testing Service, the company that prepares the College Board exams. Saunders, who knew about the Agency's involvement, found a correlation between brain (EEG) patterns and results on the digit-span test, and he helped Gittinger apply the system to other countries. In this regard, Gittinger and his colleagues understood that the Wechsler battery of subtests had a cultural bias and that a Japanese E had a very different personality from, say, a Russian E. To compensate, they worked out localized versions of the PAS for various nations around the world.

While at the Human Ecology group, Gittinger supervised much of the Society's other research in the behavioral sciences, and he always tried to interest Society grantees in his system. He looked for ways to mesh their research with his theories - and vice versa. Some, like Carl Rogers and Charles Osgood, listened politely and did not follow up. Yet Gittinger would always learn something from their work that he could apply to the PAS. A charming man and a skillful raconteur, Gittinger convinced quite a few of the other grantees of the validity of his theories and the importance of his ideas. Careful not to threaten the egos of his fellow professionals, he never projected an air of superiority. Often he would leave people even the skeptical - openmouthed in awe as he painted unnervingly accurate personality portraits of people he had never met. Indeed, people frequently accused him of somehow having cheated by knowing the subject in advance or peeking at his file.

Gittinger patiently and carefully taught his system to his colleagues, who all seem to have views of him that range from great respect to pure idolatry. For all his willingness to share the PAS, Gittinger was never able to show anyone how to use the system as skillfully as he did. Not that he did not try; he simply was a more talented natural assessor than any of the others. Moreover, his system was full of interrelations and variables that he instinctively understood but had not bothered to articulate. As a result, he could look at Wechsler scores and pick out behavior patterns which would be valid and which no one else had seen. Even after Agency officials spent a small fortune trying to computerize the PAS, they found, as one psychologist puts it, the machine "couldn't tie down all the variables" that Gittinger was carrying around in his head.

Some Human Ecology grantees, like psychiatrist Robert Hyde, were so impressed with Gittinger's system that they made the PAS a major part of their own research. Hyde routinely gave Wechslers to his subjects before plying them with liquor, as part of the Agency's efforts to find out how people react to alcohol. In 1957 Hyde moved his research team from Boston Psychopathic Hospital, where he had been America's first LSD tripper, to Butler Health Center in Providence. There, with Agency funds, Hyde built an experimental party room in the hospital, complete with pinball machine, dartboard, and bamboo bar stools. From behind a two-way mirror, psychologists watched the subjects get tipsy and made careful notes on their reaction to alcohol. Not surprisingly, the observers found that pure Internalizers became more withdrawn after several drinks, and that uncompensated Es were more likely to become garrulous - in essence, sloppy drunks. Thus Gittinger was able to make generalizations about the different ways an I or an E responded to alcohol.[2] Simply by knowing how people scored on the Wechsler digit-span test, he could predict how they would react to liquor. Hyde and Harold Abramson at Mount Sinai Hospital made the same kind of observations for LSD finding, among other things, that an E was more likely than an I to have a bad trip. (Apparently, an I is more accustomed than an E to "being into his own head" and losing touch with external reality.)

At Gittinger's urging, other Human Ecology grantees gave the Wechsler battery to their experimental subjects and sent him the scores. He was building a unique data base on all phases of human behavior, and he needed samples of as many distinct groups as possible. By getting the scores of actors, he could make generalizations about what sort of people made good role-players. Martin Orne at Harvard sent in scores of hypnosis subjects, so Gittinger could separate the personality patterns of those who easily went into a trance from those who could not be hypnotized. Gittinger collected Wechslers of businessmen, students, high-priced fashion models, doctors, and just about any other discrete group he could find a way to have tested. In huge numbers, the Wechslers came flowing in - 29,000 sets in all by the early 1970s - each one accompanied by biographic data. With the 10 subtests he used and at least 10 possible scores on each of those, no two Wechsler results in the whole sample ever looked exactly the same. Gittinger kept a computer printout of all 29,000 on his desk, and he would fiddle with them almost every day - looking constantly for new truths that could be drawn out of them.

John Gittinger was interested in all facets of personality, but because he worked for the CIA, he emphasized deviant forms. He particularly sought out Wechslers of people who had rejected the values of their society or who had some vice - hidden or otherwise - that caused others to reject them. By studying the scores of the defectors who had come over to the West, Gittinger hoped to identify common characteristics of men who had become traitors to their governments. If there were identifiable traits, Agency operators could look for them in prospective spies. Harris Isbell, who ran the MKULTRA drug-testing program at the Lexington, Kentucky detention hospital, sent in the scores of heroin addicts. Gittinger wanted to know what to look for in people susceptible to drugs. The Human Ecology project at Ionia State Hospital in Michigan furnished Wechslers of sexual psychopaths. These scores showed that people with uncontrollable urges have different personality patterns than so-called normals. Gittinger himself journeyed to the West Coast to test homosexuals, lesbians, and the prostitutes he interviewed under George White's auspices in the San Francisco safehouse. With each group, he separated out the telltale signs that might be a future indicator of their sexual preference in others. Gittinger understood that simply by looking at the Wechsler scores of someone newly tested, he could pick out patterns that corresponded to behavior of people in the data base.

The Gittinger system worked best when the TSS staff had a subject's Wechsler scores to analyze, but Agency officials could not very well ask a Russian diplomat or any other foreign target to sit down and take the tests. During World War II, OSS chief William Donovan had faced a similar problem in trying to find out about Adolf Hitler's personality, and Donovan had commissioned psychoanalyst Walter Langer to make a long-distance psychiatric profile of the German leader. Langer had sifted through all the available data on the Führer, and that was exactly what Gittinger's TSS assessments staff did when they lacked direct contact (and when they had it, too). They pored over all the intelligence gathered by operators, agents, bugs, and taps and looked at samples of a man's handwriting.[3] The CIA men took the process of "indirect assessment" one step further than Langer had, however. They observed the target's behavior and looked for revealing patterns that corresponded with traits already recorded among the subjects of the 29,000 Wechsler samples.

Along this line, Gittinger and his staff had a good idea how various personality types acted after consuming a few drinks. Thus, they reasoned, if they watched a guest at a cocktail party and he started to behave in a recognizable way - by withdrawing, for instance - they could make an educated guess about his personality type - in this case, that he was an I. In contrast, the drunken Russian diplomat who became louder and began pinching every woman who passed by probably was an E. Instead of using the test scores to predict how a person would behave, the assessments staff was, in effect, looking at behavior and working backward to predict how the person would have scored if he had taken the test. The Gittinger staff developed a whole checklist of 30 to 40 patterns that the skilled observer could look for. Each of these traits reflected one of the Wechsler subtests, and it corresponded to some insight picked up from the 29,000 scores in the data base.

Was the target sloppy or neat? Did he relate to women stiffly or easily? How did he hold a cigarette and put it into his mouth? When he went through a receiving line, did he immediately repeat the name of each person introduced to him? Taken as a whole, all these observations allowed Gittinger to make a reasoned estimate about a subject's personality, with emphasis on his vulnerabilities. As Gittinger describes the system, "If you could get a sample of several kinds of situations, you could begin to get some pretty good information." Nevertheless, Gittinger had his doubts about indirect assessment. "I never thought we were good at this," he says.

The TSS assessment staff, along with the Agency's medical office use the PAS indirectly to keep up the OSS tradition of making psychological portraits of world leaders like Hitler. Combining analytical techniques with gossipy intelligence, the assessors tried to give high-level U.S. officials a better idea of what moved the principal international political figures.[4] One such study of an American citizen spilled over into the legally forbidden domestic area when in 1971 the medical office prepared a profile of Daniel Ellsberg at the request of the White House. To get raw data for the Agency assessors, John Ehrlichman authorized a break-in at Ellsberg's psychiatrist's office in California. John Gittinger vehemently denies that his staff played any role in preparing this profile, which the White House plumbers intended to use as a kind of psychological road map to compromise Ellsberg - just as CIA operators regularly worked from such assessments to exploit the weaknesses of foreigners.

Whether used directly or indirectly, the PAS gave Agency case officers a tool to get a better reading of the people with whom they dealt. CIA field stations overseas routinely sent all their findings on a target, along with indirect assessment checklists, back to Washington, so headquarters personnel could decide whether or not to try recruitment. The TSS assessment staff contributed to this process by attempting to predict what ploys would work best on the man in the case officers' sights. "Our job was to recommend what strategy to try," says a onetime Gittinger colleague. This source states he had direct knowledge of cases where TSS recommendations led to sexual entrapment operations, both hetero- and homosexual. "We had women ready - called them a stable," he says, and they found willing men when they had to.

One CIA psychologist stresses that the PAS only provided "clues" on how to compromise people. "If somebody's assessment came in like the sexual psychopaths', it would raise red flags," he notes. But TSS staff assessors could only conclude that the target had a potentially serious sex problem. They could by no means guarantee that the target's defenses could be broken. Nevertheless, the PAS helped dictate the best weapons for the attack. "I've heard John [Gittinger] say there's always something that someone wants," says another former Agency psychologist. "And with the PAS you can find out what it is. It's not necessarily sex or booze. Sometimes it's status or recognition or security." Yet another Gittinger colleague describes this process as "looking for soft spots." He states that after years of working with the system, he still bridled at a few of the more fiendish ways "to get at people" that his colleagues dreamed up He stayed on until retirement, however, and he adds, "None of this was personal. It was for national security reasons."

A few years ago, ex-CIA psychologist James Keehner told reporter Maureen Orth that he personally went to New York in 1969 to give Wechsler tests to an American nurse who had volunteered her body for her country. "We wanted her to sleep with this Russian," explained Keehner. "Either the Russian would fall in love with her and defect, or we'd blackmail him. I had to see if she could sleep with him over a period of time and not get involved emotionally. Boy, was she tough!" Keehner noted that he became disgusted with entrapment techniques, especially after watching a film of an agent in bed with a "recruitment target." He pointed out that Agency case officers, many of whom "got their jollies" from such work, used a hidden camera to get their shots. The sexual technology developed in the MKULTRA safehouses in New York and San Francisco had been put to work. The operation worked no better in the 1960s, however, than TSS officials predicted such activities would a decade earlier. "You don't really recruit agents with sexual blackmail," Keehner concluded. "That's why I couldn't even take reading the files after a while. I was sickened at seeing people take pleasure in other people's inadequacies. First of all, I thought it was just dumb. For all the money going out, nothing ever came back."

Keehner became disgusted by the picking-at-scabs aspect of TSS assessment work. Once the PAS had identified a target as having potential mental instabilities, staff members sometimes suggested ways to break him down, reasoning that by using a ratchet-like approach to put him under increased pressure, they might be able to break the lines that tied him to his country, if not to his sanity. Keehner stated, "I was sent to deal with the most negative aspects of the human condition. It was planned destructiveness. First, you'd check to see if you could destroy a man's marriage. If you could, then that would be enough to put a lot of stress on the individual, to break him down. Then you might start a minor rumor campaign against him. Harass him constantly. Bump his car in traffic. A lot of it is ridiculous, but it may have a cumulative effect." Agency case officers might also use this same sort of stress-producing campaign against a particularly effective enemy intelligence officer whom they knew they could never recruit but whom they hoped to neutralize.

Most operations - including most recruitments - did not rely on such nasty methods. The case officer still benefited from the TSS staffs assessment, but he usually wanted to minimize stress rather than accentuate it. CIA operators tended to agree that the best way to recruit an agent was to make the relationship as productive and satisfying as possible for him, operating from the old adage about catching more flies with honey than vinegar. "You pick the thing most fearful to him - the things which would cause him the most doubt," says the source. "If his greatest fear is that he can't trust you to protect him and his family, you overload your pitch with your ability to do it. Other people need structure, so you tell them exactly what they will need to do. If you leave it open-ended, they'll be scared you'll ask them to do things they're incapable of."[5]

Soon after the successful recruitment of a foreigner to spy for the CIA, either a CIA staff member or a specially trained case officer normally sat down with the new agent and gave him the full battery of Wechsler subtests - a process that took several hours. The tester never mentioned that the exercise had anything to do with personality but called it an "aptitude" test - which it also is. The assessments office in Washington then analyzed the results. As with the polygraph, the PAS helped tell if the agent were lying. It could often delve deeper than surface concepts of true and false. The PAS might show that the agent's motivations were not in line with his behavior. In that case, if the gap were too great, the case officer could expect to run up against considerable deception - resulting either from espionage motives or psychotic tendencies.

The TSS staff assessors sent a report back to the field on the best way to deal with the new agent and the most effective means to exploit him. They would recommend whether his case officer should treat him sternly or permissively. If the agent were an Externalizer who needed considerable companionship, the assessors might suggest that the case officer try to spend as much time with him as possible.[6] They would probably recommend against sending this E agent on a long mission into a hostile country, where he could not have the friendly company he craved.

Without any help from John Gittinger or his system, covert operators had long been deciding matters like these, which were, after all, rooted in common sense. Most case officers prided themselves on their ability to play their agents like a musical instrument, at just the right tempo, and the Gittinger system did not shake their belief that nothing could beat their own intuition. Former CIA Deputy Director Ray Cline expresses a common view when he says the PAS "was part of the system - kind of a check-and-balance - a supposedly scientific tool that was not weighed very heavily. I never put as much weight on the psychological assessment reports as on a case officer's view.... In the end, people went with their own opinion." Former Director William Colby found the assessment reports particularly useful in smoothing over that "traumatic" period when a case officer had to pass on his agent to a replacement. Understandably, the agent often saw the switch as a danger or a hardship. "The new guy has to show some understanding and sympathy," says Colby, who had 30 years of operational experience himself, "but it doesn't work if these feelings are not real."

For those Agency officers who yearned to remove as much of the human element as possible from agent operations, Gittinger's system was a natural. It reduced behavior to a workable formula of shorthand letters that, while not insightful in all respects, gave a reasonably accurate description of a person. Like Social Security numbers, such formulas fitted well with a computerized approach. While not wanting to overemphasize the Agency's reliance on the PAS, former Director Colby states that the system made dealing with agents "more systematized, more professional."

In 1963 the CIA's Inspector General gave the TSS assessment staff high marks and described how it fit into operations:

> The [Clandestine Services] case officer is first and foremost, perhaps, a practitioner of the art of assessing and exploiting human personality and motivations for ulterior purposes. The ingredients of advanced skill in this art are highly individualistic in nature, including such qualities as perceptiveness and imagination. [The PAS] seeks to enhance the case officer's skill by bringing the methods and disciplines of psychology to bear.... The prime objectives are control, exploitation, or neutralization. These objectives are innately anti-ethical rather than therapeutic in their intent.

In other words, the PAS is directed toward the relationship between the American case officer and his foreign agent, that lies at the heart of espionage. In that sense, it amounts to its own academic discipline - the psychology of spying - complete with axioms and reams of empirical data. The business of the PAS, like that of the CIA, is control.

One former CIA psychologist, who still feels guilty about his participation in certain Agency operations, believes that the CIA's fixation on control and manipulation mirrors, in a more virulent form, the way Americans deal with each other generally. "I don't think the CIA is too far removed from the culture," he says. "It's just a matter of degree. If you put a lot of money out there, there are many people who are lacking the ethics even of the CIA. At least the Agency had an ideological basis." This psychologist believes that the United States has become an extremely control-oriented society - from the classroom to politics to television advertising. Spying and the PAS techniques are unique only in that they are more systematic and secret.

Another TSS scientist believes that the Agency's behavioral research was a logical extension of the efforts of American psychologists, psychiatrists, and sociologists to change behavior - which he calls their "sole motivation." Such people manipulate their subjects in trying to make mentally disturbed people well, in turning criminals into law-abiding citizens, in improving the work of students, and in pushing poor people to get off welfare. The source cites all of these as examples of "behavior modification" for socially acceptable reasons, which, like public attitudes toward spying, change from time to time. "Don't get the idea that all these behavioral scientists were nice and pure, that they didn't want to change anything, and that they were detached in their science," he warns. "They were up to their necks in changing people. It just happened that the things they were interested in were not always the same as what we were." Perhaps the saving grace of the behavioral scientists is summed up by longtime MKULTRA consultant Martin Orne: "We are sufficiently ineffective so that our findings can be published." With the PAS, CIA officials had a handy tool for social engineering. The Gittinger staff found one use for it in the sensitive area of selecting members of foreign police and intelligence agencies. All over the globe, Agency operators have frequently maintained intimate working relations with security services that have consistently mistreated their own citizens. The assessments staff played a key role in choosing members of the secret police in at least two countries whose human-rights records are among the world's worst.

In 1961, according to TSS psychologist John Winne, the CIA and the Korean government worked together to establish the newly created Korean Central Intelligence Agency (KCIA). The American CIA station in Seoul asked headquarters to send out an assessor to "select the initial cadre" of the KCIA. Off went Winne on temporary duty. "I set up an office with two translators," he recalls, "and used a Korean version of the Wechsler." The Agency psychologist gave the tests to 25 to 30 police and military officers and wrote up a half-page report on each, listing their strengths and weaknesses. Winne wanted to know about each candidate's "ability to follow orders, creativity, lack of personality disorders, motivation - why he wanted out of his current job. It was mostly for the money, especially with the civilians." The test results went to the Korean authorities, whom Winne believes made the personnel decisions "in conjunction with our operational people."

"We would do a job like this and never get feedback, so we were never sure we'd done a good job," Winne complains. Sixteen years after the end of his mission to Seoul and after news of KCIA repression at home and bribes to American congressmen abroad, Winne feels that his best efforts had "boomeranged." He states that Tongsun Park was not one of the KCIA men he tested.

In 1966 CIA staffers, including Gittinger himself, took part in selecting members of an equally controversial police unit in Uruguay - the anti-terrorist section that fought the Tupamaro urban guerrillas. According to John Cassidy, the CIA's deputy station chief there at the time, Agency operators worked to set up this special force together with the Agency for International Development's Public Safety Mission (whose members included Dan Mitrione, later kidnapped and killed by the Tupamaros). The CIA-assisted police claimed they were in a life-and-death struggle against the guerrillas, and they used incredibly brutal methods, including torture, to stamp out most of the Uruguayan left along with the guerrillas.

While the special police were being organized, "John [Gittinger] came down for three days to get the program underway," recalls Cassidy. Then Hans Greiner, a Gittinger associate, ran Wechslers on 20 Uruguayan candidates. One question on the information subtest was "How many weeks in the year?" Eighteen of the 20 said it was 48, and only one man got the answer right. (Later he was asked about his answer, and he said he had made a mistake; he meant 48.) But when Greiner asked this same group of police candidates, "Who wrote Faust?" 18 of the 20 knew it was Goethe. "This tells you something about the culture," notes Cassidy, who served the Agency all over Latin America. It also points up the difficulty Gittinger had in making the PAS work across cultural lines.

In any case, CIA man Cassidy found the assessment process most useful for showing how to train the anti-terrorist section. "According to the results, these men were shown to have very dependent psychologies and they needs d strong direction," recalls the now-retired operator. Cassidy was quite pleased with the contribution Gittinger and Greiner made. "For years I had been dealing with Latin Americans," says Cassidy, "and here, largely by psychological tests, one of [Gittinger's] men was able to analyze people he had no experience with and give me some insight into them.... Ordinarily, we would have just selected the men and gone to work on them."

In helping countries like South Korea and Uruguay pick their secret police, TSS staff members often inserted a devilish twist with the PAS. They could not only choose candidates who would make good investigators, interrogators, or whatever, but they could also spot those who were most likely to succumb to future CIA blandishments. "Certain types were more recruitable," states a former assessor. "I looked for them when I wrote my reports.... Anytime the Company [the CIA] spent money for training a foreigner, the object was that he would ultimately serve our control purposes." Thus, CIA officials were not content simply to work closely with these foreign intelligence agencies; they insisted on penetrating them, and the PAS provided a useful aid.

In 1973 John Gittinger and his longtime associate John Winne, who picked KCIA men, published a basic description of the PAS in a professional journal. Although others had written publicly about the system, this article apparently disturbed some of the Agency's powers, who were then cutting back on the number of CIA employees at the order of short-time Director James Schlesinger.

Shortly thereafter, Gittinger, then 56, stopped being president of Psychological Assessment Associates but stayed on as a consultant. In 1974 I wrote about Gittinger's work, albeit incompletely, in Rolling Stone magazine. Gittinger was disturbed that disclosure of his CIA connection would hurt his professional reputation. "Are we tarred by a brush because we worked for the CIA?" he asked during one of several rather emotional exchanges. "I'm proud of it." He saw no ethical problems in "looking for people's weaknesses" if it helped the CIA obtain information, and he declared that for many years most Americans thought this was a useful process. At first, he offered to give me the Wechsler tests and prepare a personality assessment to explain the system, but Agency officials prohibited his doing so. "I was given no explanation," said the obviously disappointed Gittinger. "I'm very proud of my professional work, and I had looked forward to being able to explain it."

In August 1977 Gittinger publicly testified in Senate hearings. While he obviously would have preferred talking about his psychological research, his most persistent questioner, Senator Edward Kennedy, was much more interested in bringing out sensational details about prostitutes and drug testing. A proud man, Gittinger felt "humiliated" by the experience, which ended with him looking foolish on national television. The next month, the testimony of his former associate, David Rhodes, further bruised Gittinger. Rhodes told the Kennedy subcommittee about Gittinger's role in leading the "Gang that Couldn't Spray Straight" in an abortive attempt to test LSD in aerosol cans on unwitting subjects. Gittinger does not want his place in history to be determined by this kind of activity. He would like to see his Personality Assessment System accepted as an important contribution to science.

Tired of the controversy and worn down by trying to explain the PAS, Gittinger has moved back to his native Oklahoma. He took a copy of the 29,000 Wechsler results with him, but he has lost his ardor for working with them. A handful of psychologists around the country still swear by the system and try to pass it on to others. One, who uses it in private practice, says that in therapy it saves six months in understanding the patient. This psychologist takes a full reading of his patient's personality with the PAS, and then he varies his treatment to fit the person's problems. He believes that most American psychologists and psychiatrists treat their patients the same whereas the PAS is designed to identify the differences between people. Gittinger very much hopes that others will accept this view and move his system into the mainstream. "It means nothing unless I can get someone else to work on it," he declares. Given the preconceptions of the psychological community, the inevitable taint arising from the CIA's role in developing the system, and Gittinger's lack of academic credentials and energy, his wish will probably not be fulfilled.

Notes 10

The material on the Gittinger Personality Assessment System (PAS) comes from "An Introduction to the Personality Assessment System" by John Winne and John Gittinger, Monograph Supplement No. 38, Clinical Psychology Publishing Co., Inc. 1973; an interview with John Winne; interviews with three other former CIA psychologists; 1974 interviews with John Gittinger by the author; and an extended interview with Gittinger by Dr. Patricia Greenfield, Associate Professor of Psychology at UCLA. Some of the material was used first in a Rolling Stone article, July 18, 1974, "The CIA Won't Quite Go Public." Robert Hyde's alcohol research at Butler Health Center was MKULTRA Subproject 66. See especially 66-17, 27 August, 1958. Subject: Proposed Alcohol Study - 1958-1959 and 66-5. undated, Subject: Equipment - Ecology Laboratory.

The 1963 Inspector General's report on TSS, as first released under the Freedom of Information Act, did not include the section on personality assessment quoted from in the chapter. An undated, untitled document, which was obviously this section, was made available in one of the CIA's last releases.

MKULTRA subproject 83 dealt with graphology research, as did part of Subproject 60, which covered the whole Human Ecology Society. See especially 83-7, December 11, 1959, Subject: [deleted] Graphological Review and 60-28, undated, Subject [deleted] Activities Report, May, 1959-April, 1960.

Information on the psychological profile of Ferdinand Marcos came from a U.S. Government source who had read it. Information on the profile of the Shah of Iran came from a column by Jack Anderson and Les Whitten "CIA Study Finds Shah Insecure," Washington Post, July 11, 1975.

The quotes from James Keehner came from an article in New Times by Maureen Orth, "Memoirs of a CIA

Psychologist," June 25, 1975.

For related reports on the CIA's role in training foreign police and its activities in Uruguay, see an article by Taylor Branch and John Marks, "Tracking the CIA," Harper's Weekly, January 25, 1975 and Philip Agee's book, Inside the Company: CIA Diary (London: Penguin; 1975).

The quote from Martin Orne was taken from Patricia Greenfield's APA Monitor article cited in the last chapter's notes.

Gittinger's testimony before the Senate Select Committee on Intelligence and the Kennedy subcommittee on August 3, 1977 appeared on pages 50-63. David Rhodes' testimony on Gittinger's role in the abortive San Francisco LSD spraying appeared in hearings before the Kennedy subcommittee, September 20, 1977, pp. 100-110.

Footnotes 10

1. Developed by psychologist David Wechsler, this testing system is called, in different versions, the Wechsler-Bellevue and the Wechsler Adult Intelligence Scale. As Gittinger worked with it over the years, he made modifications that he incorporated in what he named the Wechsler-Bellevue-G. For simplicity's sake, it is simply referred to as the Wechsler system throughout the book.
2. As with most of the descriptions of the PAS made in the book, this is an oversimplification of a more complicated process. The system, as Gittinger used it, yielded millions of distinct personality types. His observations on alcohol were based on much more than a straight I and E comparison. For the most complete description of the PAS in the open literature, see the article by Gittinger and Winne cited in the chapter notes.
3. Graphology (handwriting analysis) appealed to CIA officials as a way of supplementing PAS assessments or making judgments when only a written letter was available. Graphology was one of the seemingly arcane fields which the Human Ecology Society had investigated and found operational uses for. The Society wound up funding handwriting research and a publication in West Germany where the subject was taken much more seriously than in the United States, and it sponsored a study to compare handwriting analyses with Wechsler scores of actors (including some homosexuals), patients in psychotherapy, criminal psychopaths, and fashion models. Gittinger went on to hire a resident graphologist who could do the same sort of amazing things with handwriting as the Oklahoma psychologist could do with Wechsler scores. One former colleague recalls her spotting - accurately - a stomach ailment in a foreign leader simply by reading one letter. Asked in an interview about how the Agency used her work, she replied, "If they think they can manipulate a person, that's none of my business. I don't know what they do with it. My analysis was not done with that intention.... Something I learned very early in government was not to ask questions."
4. A profile of Ferdinand Marcos found the Filipino president's massive personal enrichment while in office to be a natural outgrowth of his country's tradition of putting loyalty to one's family and friends ahead of all other considerations. Agency assessors found the Shah of Iran to be a brilliant but dangerous megalomaniac whose problems resulted from an overbearing father, the humiliation of having served as a puppet ruler, and his inability for many years to produce a male heir.
5. This source reports that case officers usually used this sort of nonthreatening approach and switched to the rougher stuff if the target decided he did not want to spy for the CIA. In that case, says the ex-CIA man, "you don't want the person to say no and run off and tattle. You lose an asset that way - not in the sense of the case officer being shot, but by being nullified." The spurned operator might then offer not to reveal that the target was cheating on his wife or had had a homosexual affair, in return for the target not disclosing the recruitment attempt to his own intelligence service.
6. While Agency officials might also have used the PAS to select the right case officer to deal with the E agent - one who would be able to sustain the agent's need for a close relationship over a long period of time - they almost never used the system with this degree of precision. An Agency office outside TSS did keep Wechslers and other test scores on file for most case officers, but the Clandestine Services management was not willing to turn over the selection of American personnel to the psychologists.

11. Hypnosis

No mind-control technique has more captured popular imagination - and kindled fears - than hypnosis. Men have long dreamed they could use overwhelming hypnotic powers to compel others to do their bidding. And when CIA officials institutionalized that dream in the early Cold War Days, they tried, like modern-day Svengalis, to use hypnosis to force their favors on unwitting victims.

One group of professional experts, as well as popular novelists, argued that hypnosis would lead to major breakthroughs in spying. Another body of experts believed the opposite. The Agency men, who did not fully trust the academics anyway, listened to both points of view and kept looking for applications which fit their own special needs. To them, hypnosis offered too much promise not to be pursued, but finding the answers was such an elusive and dangerous process that 10 years after the program started CIA officials were still searching for practical uses.

The CIA's first behavioral research czar, Morse Allen of ARTICHOKE, was intrigued by hypnosis. He read everything he could get his hands on, and in 1951 he went to New York for a four-day course from a well-known stage hypnotist. This hypnotist had taken the Svengali legend to heart, and he bombarded Allen with tales of how he used hypnosis to seduce young women. He told the ARTICHOKE chief that he had convinced one mesmerized lady that he was her husband and that she desperately wanted him. That kind of deception has a place in covert operations, and Morse Allen was sufficiently impressed to report back to his bosses the hypnotist's claim that "he spent approximately five nights a week away from home engaging in sexual intercourse."

Apart from the bragging, the stage hypnotist did give Morse Allen a short education in how to capture a subject's attention and induce a trance. Allen returned to Washington more convinced than ever of the benefits of working hypnosis into the ARTICHOKE repertory and of the need to build a defense against it. With permission from above, he decided to take his hypnosis studies further, right in his own office. He asked young CIA secretaries to stay after work and ran them through the hypnotic paces - proving to his own satisfaction that he could make them do whatever he wanted. He had secretaries steal SECRET files and pass them on to total strangers, thus violating the most basic CIA security rules. He got them to steal from each other and to start fires. He made one of them report to the bedroom of a strange man and then go into a deep sleep. "This activity clearly indicates that individuals under hypnosis might be compromised and blackmailed," Allen wrote.

On February 19, 1954, Morse Allen simulated the ultimate experiment in hypnosis: the creation of a "Manchurian *Candida*te," or programmed assassin. Allen's "victim" was a secretary whom he put into a deep trance and told to keep sleeping until he ordered otherwise. He then hypnotized a second secretary and told her that if she could not wake up her friend, "her rage would be so great that she would not hesitate to 'kill.' " Allen left a pistol nearby, which the secretary had no way of knowing was unloaded. Even though she had earlier expressed a fear of firearms of any kind, she picked up the gun and "shot" her sleeping friend. After Allen brought the "killer" out of her trance, she had apparent amnesia for the event, denying she would ever shoot anyone.

With this experiment, Morse Allen took the testing as far as he could on a make-believe basis, but he was neither satisfied nor convinced that hypnosis would produce such spectacular results in an operational setting. All he felt he had proved was that an impressionable young volunteer would accept a command from a legitimate authority figure to take an action she may have sensed would not end in tragedy. She presumably trusted the CIA enough as an institution and Morse Allen as an individual to believe he would not let her do anything wrong. The experimental setting, in effect, legitimated her behavior and prevented it from being truly antisocial.

Early in 1954, Allen almost got his chance to try the crucial test. According to a CIA document, the subject was to be a 35-year-old, well-educated foreigner who had once worked for a friendly secret service, probably the CIA itself. He had now shifted his loyalty to another government, and the CIA was quite upset with him. The Agency plan was to hypnotize him and program him into making an assassination attempt. He would then be arrested at the least for attempted murder and "thereby disposed of." The scenario had several holes in it, as the operators presented it to the ARTICHOKE team. First, the subject was to be involuntary and unwitting, and as yet no one had come up with a consistently effective way of hypnotizing such people. Second, the

ARTICHOKE team would have only limited custody of the subject, who was to be snatched from a social event. Allen understood that it would probably take months of painstaking work to prepare the man for a sophisticated covert operation. The subject was highly unlikely to perform after just one command. Yet, so anxious were the ARTICHOKE men to try the experiment that they were willing to go ahead even under these unfavorable conditions: "The final answer was that in view of the fact that successful completion of this proposed act of attempted assassination was insignificant to the overall project; to wit, whether it was even carried out or not, that under 'crash conditions' and appropriate authority from Headquarters, the ARTICHOKE team would undertake the problem in spite of the operational limitations."

This operation never took place. Eager to be unleashed, Morse Allen kept requesting prolonged access to operational subjects, such as the double agents and defectors on whom he was allowed to work a day or two. Not every double agent would do. The candidate had to be among the one person in five who made a good hypnotic subject, and he needed to have a dissociative tendency to separate part of his personality from the main body of his consciousness. The hope was to take an existing ego state - such as an imaginary childhood playmate - and build it into a separate personality, unknown to the first. The hypnotist would communicate directly with this schizophrenic offshoot and command it to carry out specific deeds about which the main personality would know nothing. There would be inevitable leakage between the two personalities, particularly in dreams; but if the hypnotists were clever enough, he could build in cover stories and safety valves which would prevent the subject from acting inconsistently.

All during the spring and summer of 1954, Morse Allen lobbied for permission to try what he called "terminal experiments" in hypnosis, including one along the following scenario:

> CIA officials would recruit an agent in a friendly foreign country where the Agency could count on the cooperation of the local police force. CIA case officers would train the agent to pose as a leftist and report on the local communist party. During training, a skilled hypnotist would hypnotize him under the guise of giving him medical treatment (the favorite ARTICHOKE cover for hypnosis). The hypnotist would then provide the agent with information and tell him to forget it all when he snapped out of the trance. Once the agent had been properly conditioned and prepared, he would be sent into action as a CIA spy. Then Agency officials would tip off the local police that the man was a dangerous communist agent, and he would be arrested. Through their liaison arrangement with the police, Agency case officers would be able to watch and even guide the course of the interrogation. In this way, they could answer many of their questions about hypnosis on a live guinea pig who believed his life was in danger. Specifically, the men from ARTICHOKE wanted to know how well hypnotic amnesia held up against torture. Could the amnesia be broken with drugs? One document noted that the Agency could even send in a new hypnotist to try his hand at cracking through the commands of the first one. Perhaps the most cynical part of the whole scheme came at the end of the proposal: "In the event that the agent should break down and admit his connection with US intelligence, we a) deny this absolutely and advise the agent's disposal, or b) indicate that the agent may have been dispatched by some other organ of US intelligence and that we should thereafter run the agent jointly with [the local intelligence service]."

An ARTICHOKE team was scheduled to carry out field tests along these lines in the summer of 1954. The planning got to an advanced stage, with the ARTICHOKE command center in Washington cabling overseas for the "time, place, and bodies available for terminal experiments." Then another cable complained of the "diminishing numbers" of subjects available for these tests. At this point, the available record becomes very fuzzy. The minutes of an ARTICHOKE working group meeting indicate that a key Agency official - probably the station chief in the country where the experiments were going to take place - had second thoughts. One participant at the meeting, obviously rankled by the obstructionism, said if this naysayer did not change his attitude, ARTICHOKE officials would have the Director himself order the official to go along.

Although short-term interrogations of unwitting subjects with drugs and hypnosis (the "A" treatment) continued, the more complicated tests apparently never did get going under the ARTICHOKE banner. By the end of the year, 1954, Allen Dulles took the behavioral-research function away from Morse Allen and gave it to Sid Gottlieb and the men from MKULTRA. Allen had directly pursued the goal of creating a Manchurian *Candida*te, which he clearly believed was possible. MKULTRA officials were just as interested in finding ways to assert control over people, but they had much less faith in the frontal-assault approach pushed by Allen. For them, finding the Manchurian *Candida*te became a figurative exercise. They did not give up the dream. They simply pursued it in smaller steps, always hoping to increase the percentages in their favor. John Gittinger, the MKULTRA case officer on hypnosis, states, "Predictable absolute control is not possible on a particular individual. Any psychologist, psychiatrist, or preacher can get control over certain kinds of individuals, but that's not a predictable, definite thing." Gittinger adds that despite his belief to this effect, he felt he had to give "a fair shake" to people who wanted to try out ideas to the contrary.

Gottlieb and his colleagues had already been doing hypnosis research for two years. They did a few basic experiments in the office, as Morse Allen did, but they farmed out most of the work to a young Ph.*D. candida*te at the University of Minnesota, Alden Sears. Sears, who later moved his CIA study project to the University of Denver, worked with student subjects to define the nature of hypnosis. Among many other things, he looked into several of the areas that would be building blocks in the creation of a Manchurian *Candida*te. Could a hypnotist induce a totally separate personality? Could a subject be sent on missions he would not remember unless cued by the hypnotist? Sears, who has since become a Methodist minister, refused to talk about methods he experimented with to build second identities.[1] By 1957, he wrote that the experiments that needed to be done "could not be handled in the University situation." Unlike Morse Allen, he did not want to perform the terminal experiments.

Milton Kline, a New York psychologist who says he also did not want to cross the ethical line but is sure the intelligence agencies have, served as an unpaid consultant to Sears and other CIA hypnosis research. Nothing Sears or others found disabused him of the idea that the Manchurian *Candida*te is possible. "It cannot be done by everyone," says Kline, "It cannot be done consistently, but it can be done."

A onetime president of the American Society for Clinical and Experimental Hypnosis, Kline was one of many outside experts to whom Gittinger and his colleagues talked. Other consultants, with equally impressive credentials, rejected Kline's views. In no other area of the behavioral sciences was there so little accord on basic questions. "You could find an expert who would agree with everything," says Gittinger. "Therefore, we tried to get everybody."

The MKULTRA men state that they got too many unsolicited suggestions on how to use hypnosis in covert operations. "The operators would ask us for easy solutions," recalls a veteran. "We therefore kept a laundry list of why they couldn't have what they wanted. We spent a lot of time telling some young kid whose idea we had heard a hundred times why it wouldn't work. We would wind up explaining why you couldn't have a free lunch." This veteran mentions an example: CIA operators put a great deal of time and money into servicing "dead drops" (covert mail pickup points, such as a hollow tree) in the Soviet Union. If a collector was captured, he was likely to give away the locations. Therefore Agency men suggested that TSS find a way to hypnotize these secret mailmen, so they could withstand interrogation and even torture if arrested.

Morse Allen had wanted to perform the "terminal experiment" to see if a hypnotically induced amnesia would stand up to torture. Gittinger says that as far as he knows, this experiment was never carried out. "I still like to think we were human beings enough that this was not something we played with," says Gittinger. Such an experiment could have been performed, as Allen suggested, by friendly police in a country like Taiwan or Paraguay. CIA men did at least discuss joint work in hypnosis with a foreign secret service in 1962.[2] Whether they went further simply cannot be said.

Assuming the amnesia would hold, the MKULTRA veteran says the problem was how to trigger it. Perhaps the Russian phrase meaning "You're under arrest" could be used as a preprogrammed cue, but what if the police did not use these words as they captured the collector? Perhaps the physical sensation of handcuffs being snapped on could do it, but a metal watchband could have the same effect. According to the veteran, in the abstract, the scheme sounded fine, but in practicality, a foolproof way of triggering the amnesia could not be found. "You had to accept that when someone is caught, they're going to tell some things," he says.

MKULTRA officials, including Gittinger, did recommend the use of hypnosis in operational experiments on at least one occasion. In 1959 an important double agent, operating outside his homeland, told his Agency case officer that he was afraid to go home again because he did not think he could withstand the tough interrogation that his government used on returning overseas agents. In Washington, the operators approached the TSS men about using hypnosis, backed up with drugs, to change the agent's attitude. They hoped they could instill in him the "ability or the necessary will" to hold up under questioning.

An MKULTRA official - almost certainly Gittinger - held a series of meetings over a two-week period with the operators and wrote that the agent was "a better than average" hypnotic subject, but that his goal was to get out of intelligence work: The agent "probably can be motivated to make at least one return visit to his homeland by application of any one of a number of techniques, including hypnosis, but he may redefect in the process." The MKULTRA official continued that hypnosis probably could not produce an "operationally useful" degree of amnesia for the events of the recent past or for the hypnotic treatment itself that the agent "probably has the native ability to withstand ordinary interrogation ... provided it is to his advantage to do so."

The MKULTRA office recommended that despite the relatively negative outlook for the hypnosis, the Agency should proceed anyway. The operation had the advantage of having a "fail-safe" mechanism because the level of hypnosis could be tested out before the agent actually had to return. Moreover, the MKULTRA men felt "that a considerable amount of useful experience can be gained from this operation which could be used to improve Agency capability in future applications." In effect, they would be using hypnosis not as the linchpin of the operation, but as an adjunct to help motivate the agent.

Since the proposed operation involved the use of hypnosis and drugs, final approval could only be given by the high-level Clandestine Services committee set up for this purpose and chaired by Richard Helms. Permission was not forthcoming.

In June 1960 TSS officials launched an expanded program of operational experiments in hypnosis in cooperation with the Agency's Counterintelligence Staff. The legendary James Angleton - the prototype for the title character Saxonton in Aaron Latham's Orchids for Mother and for Wellington in Victor Marchetti's The Rope Dancer - headed Counterintelligence, which took on some of the CIA's most sensitive missions (including the illegal Agency spying against domestic dissidents). Counterintelligence officials wrote that the hypnosis program could provide a "potential breakthrough in clandestine technology." Their arrangement with TSS was that the MKULTRA men would develop the technique in the laboratory, while they took care of "field experimentation."

The Counterintelligence program had three goals: (1) to induce hypnosis very rapidly in unwitting subjects; (2) to create durable amnesia; and (3) to implant durable and operationally useful posthypnotic suggestion. The Agency released no information on any "field experimentation" of the latter two goals, which of course are the building blocks of the Manchurian *Candida*te. Agency officials provided only one heavily censored document on the first goal, rapid induction.

In October 1960 the MKULTRA program invested $9,000 in an outside consultant to develop a way of quickly hypnotizing an unwitting subject. John Gittinger says the process consisted of surprising "somebody sitting in a chair, putting your hands on his forehead, and telling the guy to go to sleep." The method worked "fantastically" on certain people, including some on whom no other technique was effective, and not on others. "It wasn't that predictable," notes Gittinger, who states he knows nothing about the field testing.

The test, noted in that one released document, did not take place until July 1963 - a full three years after the Counterintelligence experimental program began, during which interval the Agency is claiming that no other field experiments took place. According to a CIA man who participated in this test, the Counterintelligence Staff in Washington asked the CIA station in Mexico City to find a suitable candidate for a rapid induction experiment. The station proposed a low-level agent, whom the Soviets had apparently doubled. A Counterintelligence man flew in from Washington and a hypnotic consultant arrived from California. Our source and a fellow case officer brought the agent to a motel room on a pretext. "I puffed him up with his importance," says the Agency man. "I said the bosses wanted to see him and of course give him more money." Waiting in an adjoining room was the hypnotic consultant. At a prearranged time, the two case officers gently grabbed hold of the agent and tipped his chair over until the back was touching the floor. The consultant was supposed to rush in at that precise moment and apply the technique. Nothing happened. The consultant froze, unable to do the deed. "You can imagine what we had to do to cover-up," says the official, who was literally left holding the agent. "We explained we had heard a noise, got excited, and tipped him down to protect him. He was so grubby for money he would have believed any excuse."

There certainly is a huge difference between the limited aim of this bungled operation and one aimed at building a Manchurian *Candida*te. The MKULTRA veteran maintains that he and his colleagues were not interested in a programmed assassin because they knew in general it would not work and, specifically, that they could not exert total control. "If you have one hundred percent control, you have one hundred percent dependency," he says. "If something happens and you haven't programmed it in, you've got a problem. If you try to put flexibility in, you lose control. To the extent you let the agent choose, you don't have control." He admits that he and his colleagues spent hours running the arguments on the Manchurian *Candida*te back and forth. "Castro was naturally our discussion point," he declares. "Could you get somebody gung-ho enough that they would go in and get him?" In the end, he states, they decided there were more reliable ways to kill people. "You can get exactly the same thing from people who are hypnotizable by many other ways, and you can't get anything out of people who are not hypnotizable, so it has no use," says Gittinger.

The only real gain in employing a hypnotized killer would be, in theory, that he would not remember who ordered him to pull the trigger. Yet, at least in the Castro case, the Cuban leader already knew who was after him. Moreover, there were plenty of people around willing to take on the Castro contract. "A well-trained person could do it without all this mumbo-jumbo," says the MKULTRA veteran. By going to the Mafia for hitmen, CIA officials in any case found killers who had a built-in amnesia mechanism that had nothing to do with hypnosis.[3]

The MKULTRA veteran gives many reasons why he believes the CIA never actually tried a Manchurian *Candida*te operation, but he acknowledges that he does not know.[4] If the ultimate experiments were performed, they would have been handled with incredible secrecy. It would seem, however, that the same kind of reasoning that impelled Sid Gottlieb to recommend testing powerful drugs on unwitting subjects would have led to experimentation along such lines, if not to create the Manchurian *Candida*te itself, on some of the building blocks, or lesser antisocial acts. Even if the MKULTRA men did not think hypnosis would work operationally, they had not let that consideration prevent them from trying out numerous other techniques. The MKULTRA chief could even have used a defensive rationale: He had to find out if the Russians could plant a "sleeper" killer in our midst, just as Richard Condon's novel discussed.

If the assassin scenario seemed exaggerated, Gottlieb still would have wanted to know what other uses the Russians might try. Certainly, he could have found relatively "expendable" subjects, as he and Morse Allen had for other behavior control experiments. And even if the MKULTRA men really did restrain themselves, it is unlikely that James Angleton and his counterintelligence crew would have acted in such a limited fashion when they felt they were on the verge of a "breakthrough in clandestine technology."

Notes 11

Morse Allen's training in hypnosis was described in Document #A/B, V,28/1, 9 July 1951, Subject [Deleted]. His hypnosis experiments in the office are described in a long series of memos. See especially #A/B, III, 2/18, 10 February 1954, Hypnotic Experimentation and Research and #A/B, II, 10/71, 19 August 1954, Subject: Operational/Security [deleted] and unnumbered document, 5 May 1955, Subject: Hypnotism and Covert Operations.

The quote on U.S. prisoners passing through Manchuria came from document #19, 18 June 1953, ARTICHOKE Conference.

Alden Sears' hypnosis work was the subject of MKULTRA subprojects 5, 25, 29, and 49. See especially 49-28, undated, Proposal for Research in Hypnosis at the [deleted], June 1, 1956 to May 31, 1957, 49-34, undated, Proposals for Research in Hypnosis at the [deleted], June 1, 1956 to May 31, 1957; 5-11, 28 May 1953, Project MKULTRA, Subproject 5 and 5-13,20 April 1954, Subject: [deleted]. See also Patrick Oster's article in the Chicago Sun-Times, September 4, 1977, "How CIA 'Hid' Hypnosis Research."

General background on hypnosis came from interviews with Alden Sears, Martin Orne, Milton Kline, Ernest Hilgard, Herbert Spiegel, William Kroger, Jack Tracktir, John Watkins, and Harold Crasilneck. See Orne's chapter on hypnosis in The Manipulation of Human Behavior, edited by Albert Biderman and Herbert Zimmer (New York: John Wiley & Sons; 1961), pp. 169-215.

The contemplated use of hypnosis in an operation involving a foreign intelligence service is referred to in the Affidavit by Eloise R. Page, in the case John D. Marks v. Central Intelligence Agency *et al*., Civil Action no. 76-2073.

The 1959 proposed use of hypnosis that was approved by TSS is described in documents #433, 21 August 1959, Possible Use of Drugs and Hypnosis in [deleted] Operational Case; #434, 27 August 1959, Comments on [deleted]; and #435, 15 September 1959, Possible Use of Drugs and Hypnosis in [deleted] Operational Case.

MKULTRA Subproject 128 dealt with the rapid induction technique. See especially 128-1, undated, Subject: To test a method of rapid hypnotic induction in simulated and real operational settings (MKULTRA 128).

A long interview with John Gittinger added considerably to this chapter. Mr. Gittinger had refused earlier to be interviewed directly by me for this book. Our conversation was limited solely to hypnosis.

Footnotes 11

1. Sears still maintains the fiction that he thought he was dealing only with a private foundation, the Geschickter Fund, and that he knew nothing of the CIA involvement in funding his work. Yet a CIA document in his MKULTRA subproject says he was "aware of the real purpose" of the project." Moreover, Sid Gottlieb brought him to Washington in 1954 to demonstrate hypnosis to a select group of Agency officials.
2. Under my Freedom of Information suit, the CIA specifically denied access to the documents concerning the testing of hypnosis and psychedelic drugs in cooperation with foreign intelligence agencies. The justification given was that releasing such documents would reveal intelligence sources and methods, which are exempted by law. The hypnosis experiment was never carried out, according to the generic description of the document which the Agency had to provide in explaining why it had to be withheld.
3. Referring to this CIA-mob relationship, author Robert Sam Anson has written, "It was inevitable: Gentlemen wishing to be killers gravitated to killers wishing to be gentlemen."
4. The veteran admits that none of the arguments he uses against a conditioned assassin would apply to a programmed "patsy" whom a hypnotist could walk through a series of seemingly unrelated events - a visit to a store, a conversation with a mailman, picking a fight at a political rally. The subject would remember everything that happened to him and be amnesic only for the fact the hypnotist ordered him to do these things. There would be no gaping inconsistency in his life of the sort that can ruin an attempt by a hypnotist to create a second personality. The purpose of this exercise is to leave a circumstantial trail that will make the authorities think the patsy committed a particular crime. The weakness might well be that the amnesia would not hold up under police interrogation, but that would not matter if the police did not believe his preposterous story about being hypnotized or if he were shot resisting arrest. Hypnosis expert Milton Kline says he could create a patsy in three months- an assassin would take him six.

Part IV - Conclusions

12. The Search for the Truth

I'm a professional and I just don't talk about these things. Lots of things are not fit for the public. This has nothing to do with democracy. It has to do with common sense.
- GRATION H. YASETEVITCH, 1978
(explaining why he did not want to be interviewed for this book)

To hope that the power that is being made available by the behavioral sciences will be exercised by the scientists, or by a benevolent group, seems to me to be a hope little supported by either recent or distant history. It seems far more likely that behavioral scientists, holding their present attitudes, will be in the position of the German rocket scientists specializing in guided missiles. First they worked devotedly for Hitler to destroy the USSR and the United States. Now, depending on who captured them they work devotedly for the USSR in the interest of destroying the United States, or devotedly for the United States in the interest of destroying the USSR. If behavioral scientists are concerned solely with advancing their science it seems most probable that they will serve the purpose of whatever group has the power.
- CARL ROGERS, 1961

Sid Gottlieb was one of many CIA officials who tried to find a way to assassinate Fidel Castro. Castro survived, of course, and his victory over the Agency in April 1961 at the Bay of Pigs put the Agency in the headlines for the first time, in a very unfavorable light. Among the fiasco's many consequences was Gottlieb's loss of the research part of the CIA's behavior-control programs. Still, he and the others kept trying to kill Castro.

In the aftermath of the Bay of Pigs, President Kennedy reportedly vowed to splinter the CIA into a thousand pieces. In the end, he settled for firing Allen Dulles and his top deputies. To head the Agency, which lost none of its power, Kennedy brought in John McCone, a defense contractor and former head of the Atomic Energy Commission. With no operational background, McCone had a different notion than Dulles of how to manage the CIA, particularly in the scientific area. "McCone never felt akin to the covert way of doing things," recalls Ray Cline, whom the new Director made his Deputy for Intelligence. McCone apparently believed that science should be in the hands of the scientists, not the clandestine operators, and he brought in a fellow Californian, an aerospace "whiz kid" named Albert "Bud" Wheelon to head a new Agency Directorate for Science and Technology.

Before then, the Technical Services Staff (TSS), although located in the Clandestine Services, had been the Agency's largest scientific component. McCone decided to strip TSS of its main research functions - including the behavioral one - and let it concentrate solely on providing operational support. In 1962 he approved a reorganization of TSS that brought in Seymour Russell, a tough covert operator, as the new chief. "The idea was to get a close interface with operations," recalls an ex-CIA man. Experienced TSS technicians remained as deputies to the incoming field men, and the highest deputyship in all TSS went to Sid Gottlieb, who became number-two man under Russell. For Gottlieb, this was another significant promotion helped along by his old friend Richard Helms, whom McCone had elevated to be head of the Clandestine Services.

In his new job, Gottlieb kept control of MKULTRA. Yet, in order to comply with McCone's command on research programs, Gottlieb had to preside over the partial dismantling of his own program. The loss was not as difficult as it might have been, because, after 10 years of exploring the frontiers of the mind, Gottlieb had a clear idea of what worked and what did not in the behavioral field. Those areas that still were in the research stage tended to be extremely esoteric and technical, and Gottlieb must have known that if the Science Directorate scored any breakthroughs, he would be brought back into the picture immediately to apply the advances to covert operations.

"Sid was not the kind of bureaucrat who wanted to hold on to everything at all costs," recalls an admiring colleague. Gottlieb carefully pruned the MKULTRA lists, turning over to the Science Directorate the exotic subjects that showed no short-term operational promise and keeping for himself those psychological, chemical, and biological programs that had already passed the research stage. As previously stated, he moved John Gittinger and the personality-assessment staff out of the Human Ecology Society and kept them under TSS control in their own proprietary company.

While Gottlieb was effecting these changes, his programs were coming under attack from another quarter. In 1963 the CIA Inspector General did the study that led to the suspension of unwitting drug testing in the San Francisco and New York safehouses. This was a blow to Gottlieb, who clearly intended to hold on to this kind of research. At the same time, the Inspector General also recommended that Agency officials draft a new charter for the whole MKULTRA program, which still was exempt from most internal CIA controls. He found that many of the MKULTRA subprojects were of "insufficient sensitivity" to justify bypassing the Agency's normal procedures for approving and storing records of highly classified programs. Richard Helms, still the protector of unfettered behavioral research, responded by agreeing that there should be a new charter - on the condition that it be almost the same as the old one. "The basic reasons for requesting waiver of standardized administrative controls over these sensitive activities are as valid today as they were in April, 1953," Helms wrote. Helms agreed to such changes as having the CIA Director briefed on the programs twice a year, but he kept the approval process within his control and made sure that all the files would be retained inside TSS. And as government officials so often do when they do not wish to alter anything of substance, he proposed a new name for the activity. In June 1964 MKULTRA became MKSEARCH.[1]

Gottlieb acknowledged that security did not require transferring all the surviving MKULTRA subprojects over to MKSEARCH. He moved 18 subprojects back into regular Agency funding channels, including ones dealing with the sneezing powders, stink bombs, and other "harassment substances." TSS officials had encouraged the development of these as a way to make a target physically uncomfortable and hence to cause short-range changes in his behavior.

Other MKULTRA subprojects dealt with ways to maximize stress on whole societies. Just as Gittinger's Personality Assessment System provided a psychological road map for exploiting an individual's weaknesses, CIA "destabilization" plans provided guidelines for destroying the internal integrity of target countries like Castro's Cuba or Allende's Chile. Control - whether of individuals or nations - has been the Agency's main business, and TSS officials supplied tools for the "macro" as well as the "micro" attacks.

For example, under MKULTRA Subproject #143, the Agency gave Dr. Edward Bennett of the University of Houston about $20,000 a year to develop bacteria to sabotage petroleum products. Bennett found a substance that, when added to oil, fouled or destroyed any engine into which it was poured. CIA operators used exactly this kind of product in 1967 when they sent a sabotage team made up of Cuban exiles into France to pollute a shipment of lubricants bound for Cuba. The idea was that the tainted oil would "grind out motors and cause breakdowns," says an Agency man directly involved. This operation, which succeeded, was part of a worldwide CIA effort that lasted through the 1960s into the 1970s to destroy the Cuban economy.[2] Agency officials reasoned, at least in the first years, that it would be easier to overthrow Castro if Cubans could be made unhappy with their standard of living. "We wanted to keep bread out of the stores so people were hungry," says the CIA man who was assigned to anti-Castro operations. "We wanted to keep rationing in effect and keep leather out, so people got only one pair of shoes every 18 months."

Leaving this broader sort of program out of the new structure, Gottlieb regrouped the most sensitive behavioral activities under the MKSEARCH umbrella. He chose to continue seven projects, and the ones he picked give a good indication of those parts of MKULTRA that Gottlieb considered important enough to save. These included none of the sociological studies, nor the search for a truth drug. Gottlieb put the emphasis on chemical and biological substances - not because he thought these could be used to turn men into robots, but because he valued them for their predictable ability to disorient, discredit, injure, or kill people. He kept active two private labs to produce such substances, funded consultants who had secure ways to test them and ready access to subjects, and maintained a funding conduit to pass money on to these other contractors. Here are the seven surviving MKSEARCH subprojects:

> First on the TSS list was the safehouse program for drug testing run by George White and others in the Federal Bureau of Narcotics. Even in 1964, Gottlieb and Helms had not given up hope that unwitting experiments could be resumed, and the Agency paid out $30,000 that year to keep the safehouses open. In the meantime, something was going on at the "pad" - or at least George White kept on sending the CIA vouchers for unorthodox expenses - $1,100 worth in February 1965 alone under the old euphemism for prostitutes, "undercover agents for operations." What

> White was doing with or to these agents cannot be said, but he kept the San Francisco operation active right up until the time it finally closed in June. Gottlieb did not give up on the New York safehouse until the following year.[3]

MKSEARCH Subproject #2 involved continuing a $150,000a-year contract with a Baltimore biological laboratory This lab, run by at least one former CIA germ expert, gave TSS "a quick-delivery capability to meet anticipated future operational needs," according to an Agency document. Among other things, it provided a private place for "large-scale production of microorganisms." The Agency was paying the Army Biological Laboratory at Fort Detrick about $100,000 a year for the same services. With its more complete facilities, Fort Detrick could be used to create and package more esoteric bacteria, but Gottlieb seems to have kept the Baltimore facility going in order to have a way of producing biological weapons without the Army's germ warriors knowing about it. This secrecy-within-secrecy was not unusual when TSS men were dealing with subjects as sensitive as infecting targets with diseases. Except on the most general level, no written records were kept on the subject. Whenever an operational unit in the Agency asked TSS about obtaining a biological weapon, Gottlieb or his aides automatically turned down the request unless the head of the Clandestine Services had given his prior approval. Gottlieb handled these operational needs personally, and during the early 1960s (when CIA assassination attempts probably were at their peak) even Gottlieb's boss, the TSS chief, was not told what was happening.

With his biological arsenal assured, Gottlieb also secured his chemical flank in MKSEARCH. Another subproject continued a relationship set up in 1959 with a prominent industrialist who headed a complex of companies, including one that custom-manufactured rare chemicals for pharmaceutical producers. This man, whom on several occasions CIA officials gave $100 bills to pay for his products, was able to perform specific lab jobs for the Agency without consulting with his board of directors. In 1960 he supplied the Agency with 3 kilos (6.6 pounds) of a deadly carbamate - the same poison OSS's Stanley Lovell tried to use against Hitler.[4] This company president also was useful to the Agency because he was a ready source of information on what was going on in the chemical world. The chemical services he offered, coupled with his biological counterpart, gave the CIA the means to wage "instant" chemical and biological attacks - a capability that was frequently used, judging by the large numbers of receipts and invoices that the CIA released under the Freedom of Information Act.

With new chemicals and drugs constantly coming to their attention through their continuing relations with the major pharmaceutical companies, TSS officials needed places to test them, particularly after the safehouses closed. Dr. James Hamilton, the San Francisco psychiatrist who worked with George White in the original OSS marijuana days, provided a way. He became MKSEARCH Subproject #3.

Hamilton had joined MKULTRA in its earliest days and had been used as a West Coast supervisor for Gottlieb and company. Hamilton was one of the renaissance men of the program, working on everything from psychochemicals to kinky sex to carbon-dioxide inhalation. By the early 1960s, he had arranged to get access to prisoners at the California Medical Facility at Vacaville.[5] Hamilton worked through a nonprofit research institute connected to the Facility to carry out, as a document puts it, "clinical testing of behavioral control materials" on inmates. Hamilton's job was to provide "answers to specific questions and solutions to specific problems of direct interest to the Agency." In a six-month span in 1967 and 1968, the psychiatrist spent over $10,000 in CIA funds simply to pay volunteers - which at normal rates meant he experimented on between 400 to 1,000 inmates in that time period alone.

Another MKSEARCH subproject provided $20,000 to $25,000 a year to Dr. Carl Pfeiffer. Pfeiflfer's Agency connection went back to 1951, when he headed the Pharmacology Department at the University of Illinois Medical School. He then moved to Emory University and tested LSD and other drugs on inmates of the Federal penitentiary in Atlanta. From there, he moved to New Jersey, where he continued drug experiments on the prisoners at the Bordentown reformatory. An internationally known pharmacologist, Pfeiffer provided the MKSEARCH program with data on the preparation, use, and effect of drugs. He was readily available if Gottlieb or a colleague wanted a study made of the properties of a particular substance, and like most of TSS's contractors, he also was an intelligence source. Pfeiffer was useful in this last capacity during the latter part of the 1960s because he sat on the Food and Drug Administration committee that allocated LSD for scientific research in the United States. By this time, LSD was so widely available on the black market that the Federal Government had replaced the CIA's informal controls of the 1950s with laws and procedures forbidding all but the most strictly regulated research. With Pfeiffer on the governing committee, the CIA could keep up its traditional role of monitoring above-ground LSD experimentation around the United States.

To cover some of the more exotic behavioral fields, another MKSEARCH program continued TSS's relationship with Dr. Maitland Baldwin, the brain surgeon at the National Institutes of Health who had been so willing in 1955 to perform "terminal experiments" in sensory deprivation for Morse Allen and the ARTICHOKE program. After Allen was pushed aside by the men from MKULTRA, the new TSS team hired Baldwin as a consultant According to one of them, he was full of bright ideas on how to control behavior, but they were wary of him because he was such an "eager beaver" with an obvious streak of "craziness." Under TSS auspices, Baldwin performed lobotomies on apes and then put these simian subjects into sensory deprivation - presumably in the same "box" he had built himself at NIH and then had to repair after a desperate soldier kicked his way out. There is no information available on whether Baldwin extended this work to humans, although he did discuss with an outside consultant how lobotomized patients reacted to prolonged isolation. Like Hamilton, Baldwin was a jack-of-all trades who in one experiment beamed radio frequency energy directly at the brain of a chimpanzee and in another cut off one monkey's head and tried to transplant it to the decapitated body of another monkey. Baldwin used $250 in Agency money to buy his own electroshock machine, and he did some kind of unspecified work at a TSS safehouse that caused the CIA to shell out $1450 to renovate and repair the place.

The last MKSEARCH subproject covered the work of Dr. Charles Geschickter, who served TSS both as researcher and funding conduit. CIA documents show that Geschickter tested powerful drugs on mental defectives and terminal cancer patients, apparently at the Georgetown University Hospital in Washington. In all, the Agency put $655,000 into Geschickter's research on knockout drugs, stress-producing chemicals, and mind-altering substances. Nevertheless, the doctor's principal service to TSS officials seems to have been putting his family foundation at the disposal of the CIA - both to channel funds and to serve as a source of cover to Agency operators. About $2.1 million flowed through this tightly controlled foundation to other researchers.[6] Under MKSEARCH, Geschickter continued to provide TSS with a means to assess drugs rapidly, and he branched out into trying to knock out monkeys with radar waves to the head (a technique which worked but risked frying vital parts of the brain). The Geschickter Fund for Medical Research remained available as a conduit until 1967.[7]

As part of the effort to keep finding new substances to test within MKSEARCH, Agency officials continued their search for magic mushrooms, leaves, roots, and barks. In 1966, with considerable CIA backing, J. C. King, the former head of the Agency's Western Hemisphere Division who was eased out after the Bay of Pigs, formed an ostensibly private firm called Amazon Natural Drug Company. King, who loved to float down jungle rivers on the deck of his houseboat with a glass of scotch in hand, searched the backwaters of South America for plants of interest to the Agency and/or medical science. To do the work, he hired Amazon men and women, plus at least two CIA paramilitary operators who worked out of Amazon offices in Iquitos, Peru. They shipped back to the United States finds that included Chondodendron toxicoferum, a paralytic agent which is "absolutely lethal in high doses," according to Dr. Timothy Plowman, a Harvard botanist who like most of the staff was unwitting of the CIA involvement. Another plant that was collected and grown by Amazon employees was the hallucinogen known as yage, which author William Burroughs has described as "the final fix."

MKSEARCH went on through the 1960s and into the early 1970s, but with a steadily decreasing budget. In 1964 it cost the Agency about $250,000. In 1972 it was down to four subprojects and $110,000. Gottlieb was a very busy man by then, having taken over all TSS in 1967 when his patron, Richard Helms finally made it to the top of the Agency. In June 1972 Gottlieb decided to end MKSEARCH, thus bringing down the curtain on the quest he himself had started two decades before. He wrote this epitaph for the program:

> As a final commentary, I would like to point out that, by means of Project MKSEARCH, the Clandestine Service has been able to maintain contact with the leading edge of developments in the field of biological and chemical control of human behavior. It has become increasingly obvious over the last several years that this general area had less and less relevance to current clandestine operations. The reasons for this are many and complex, but two of them are perhaps worth mentioning briefly. On the scientific side, it has become very clear that these materials and techniques are too unpredictable in their effect on individual human beings, under specific circumstances, to be operationally useful. Our operations officers, particularly the emerging

> group of new senior operations officers, have shown a discerning and perhaps commendable distaste for utilizing these materials and techniques. They seem to realize that, in addition to moral and ethical considerations, the extreme sensitivity and security constraints of such operations effectively rule them out.

About the time Gottlieb wrote these words, the Watergate break-in occurred, setting in train forces that would alter his life and that of Richard Helms. A few months later, Richard Nixon was reselected. Soon after the election, Nixon, for reasons that have never been explained, decided to purge Helms. Before leaving to become Ambassador to Iran, Helms presided over a wholesale destruction of documents and tapes - presumably to minimize information that might later be used against him. Sid Gottlieb decided to follow Helms into retirement, and the two men mutually agreed to get rid of all the documentary traces of MKULTRA. They had never kept files on the safehouse testing or similarly sensitive operations in the first place, but they were determined to erase the existing records of their search to control human behavior. Gottlieb later told a Senate committee that he wanted to get rid of the material because of a "burgeoning paper problem" within the Agency, because the files were of "no constructive use" and might be "misunderstood," and because he wanted to protect the reputations of the researchers with whom he had collaborated on the assurance of secrecy. Gottlieb got in touch with the men who had physical custody of the records, the Agency's archivists, who proceeded to destroy what he and Helms thought were the only traces of the program. They made a mistake, however - or the archivists did. Seven boxes of substantive records and reports were incinerated, but seven more containing invoices and financial records survived - apparently due to misfiling.

Nixon named James Schlesinger to be the new head of the Agency, a post in which he stayed only a few months before the increasingly beleaguered President moved him over to be Secretary of Defense at the height of Watergate. During his short stop at CIA, Schlesinger sent an order to all Agency employees asking them to let his office know about any instances where Agency officials might have carried out any improper or illegal actions. Somebody mentioned Frank Olson's suicide, and it was duly included in the many hundreds of pages of misdeeds reported which became known within the CIA as the "family jewels."

Schlesinger, an outsider to the career CIA operators, had opened a Pandora's box that the professionals never managed to shut again. Samples of the "family jewels" were slipped out to New York Times reporter Seymour Hersh, who created a national furor in December 1974 when he wrote about the CIA's illegal spying on domestic dissidents during the Johnson and Nixon years. President Gerald Ford appointed a commission headed by Vice-President Nelson Rockefeller to investigate the past CIA abuses - and to limit the damage. Included in the final Rockefeller report was a section on how an unnamed Department of the Army employee had jumped out of a New York hotel window after Agency men had slipped him LSD. That revelation made headlines around the country. The press seized upon the sensational details and virtually ignored two even more revealing sentences buried in the Rockefeller text: "The drug program was part of a much larger CIA program to study possible means for controlling human behavior. Other studies explored the effects of radiation, electric-shock, psychology, psychiatry, sociology, and harassment substances."

At this point, I entered the story. I was intrigued by those two sentences, and I filed a Freedom of Information request with the CIA to obtain all the documents the Agency had furnished the Rockefeller Commission on behavior control. Although the law requires a government agency to respond within 10 days, it took the Agency more than a year to send me the first 50 documents on the subject, which turned out to be heavily censored.

In the meantime, the committee headed by Senator Frank Church was looking into the CIA, and it called in Sid Gottlieb, who was then spending his retirement working as a volunteer in a hospital in India. Gottlieb secretly testified about CIA assassination programs. (In describing his role in its final report, the Church Committee used a false name, "Victor Scheider.") Asked about the behavioral-control programs, Gottlieb apparently could not - or would not - remember most of the details. The committee had almost no documents to work with, since the main records had been destroyed in 1973 and the financial files had not yet been found.

The issue lay dormant until 1977, when, about June 1, CIA officials notified my lawyers that they had found the 7 boxes of MKULTRA financial records and that they would send me the releasable portions over the following months. As I waited, CIA Director Stansfield Turner notified President Carter and then the Senate Select Committee on Intelligence that an Agency official had located the 7 boxes. Admiral Turner publicly described

MKULTRA as only a program of drug experimentation and not one aimed at behavior control. On July 20 I held a press conference at which I criticized Admiral Turner for his several distortions in describing the MKULTRA program. To prove my various points, I released to the reporters a score of the CIA documents that had already come to me and that gave the flavor of the behavioral efforts. Perhaps it was a slow news day, or perhaps people simply were interested in government attempts to tamper with the mind. In any event, the documents set off a media bandwagon that had the story reported on all three network television news shows and practically everywhere else.

The Senate Select Committee on Intelligence and Senator Edward Kennedy's Subcommittee on Health and Scientific Research soon announced they would hold public hearings on the subject. Both panels had looked into the secret research in 1975 but had been hampered by the lack of documents and forthcoming witnesses. At first the two committees agreed to work together, and they held one joint hearing. Then, Senator Barry Goldwater brought behind-the-scenes pressure to get the Intelligence panel, of which he was vice-chairman, to drop out of the proceedings. He claimed, among other things, that the committee was just rehashing old programs and that the time had come to stop dumping on the CIA. Senator Kennedy plowed ahead anyway. He was limited, however, by the small size of the staff he assigned to the investigation, and his people were literally buried in paper by CIA officials, who released 8,000 pages of documents in the weeks before the hearings. As the hearings started, the staff still not had read everything - let alone put it all in context.

As Kennedy's staff prepared for the public sessions, the former men from MKULTRA also got ready. According to one of them, they agreed among themselves to "keep the inquiry within bounds that would satisfy the committee." Specifically, he says that meant volunteering no more information than the Kennedy panel already had. Charles Siragusa, the narcotics agent who ran the New York safehouse, reports he got a telephone call during this period from Ray Treichler, the Stanford Ph.D. who specialized in chemical warfare for the MKULTRA program. "He wanted me to deny knowing about the safehouse," says Siragusa. "He didn't want me to admit that he was the guy.... I said there was no way I could do that." Whether any other ex-TSS men also suborned perjury cannot be said, but several of them appear to have committed perjury at the hearings.[8] As previously noted, Robert Lashbrook denied firsthand knowledge of the safehouse operation when, in fact, he had supervised one of the "pads" and been present, according to George White's diary, at the time of an "LSD surprise" experiment. Dr. Charles Geschickter testified he had not tested stress-producing drugs on human subjects while both his own 1960 proposal to the Agency and the CIA's documents indicate the opposite.

Despite the presence of a key aide who constantly cued him during the hearings, Senator Kennedy was not prepared to deal with these and other inconsistencies. He took no action to follow up obviously perjured testimony, and he seemed content to win headlines with reports of "The Gang That Couldn't Spray Straight." Although that particular testimony had been set up in advance by a Kennedy staffer, the Senator still managed to act surprised when ex-MKULTRA official David Rhodes told of the ill-fated LSD experiment at the Marin County safehouse.

The Kennedy hearings added little to the general state of knowledge on the CIA's behavior-control programs. CIA officials, both past and present, took the position that basically nothing of substance was learned during the 25-odd years of research, the bulk of which had ended in 1963, and they were not challenged. That proposition is, on its face, ridiculous, but neither Senator Kennedy nor any other investigator has yet put any real pressure on the Agency to reveal the content of the research - what was actually learned - as opposed to the experimental means of carrying it out. In this book, I have tried to get at some of the substantive questions, but I have had access to neither the scientific records, which Gottlieb and Helms destroyed, nor the principal people involved. Gottlieb, for instance, who moved from India to Santa Cruz, California and then to parts unknown, turned down repeated requests to be interviewed. "I am interested in very different matters than the subject of your book these days," he wrote, "and do not have either the time or the inclination to reprocess matters that happened a long time ago."

Faced with these obstacles, I have tried to weave together a representative sample of what went on, but having dealt with a group of people who regularly incorporated lying into their daily work, I cannot be sure. I cannot be positive that they never found a technique to control people, despite my definite bias in favor of the idea that the human spirit defeated the manipulators. Only a congressional committee could compel truthful testimony from people who have so far refused to be forthcoming, and even Congress' record has not been good so far. A determined investigative committee at least could make sure that the people being probed do not determine the "bounds" of the inquiry.

A new investigation would probably not be worth the effort just to take another stab at MKULTRA and ARTICHOKE. Despite my belief that there are some skeletons hidden - literally - the public probably now knows the basic parameters of these programs. The fact is, however, that CIA officials actively experimented with behavior-control methods for another decade after Sid Gottlieb and company lost the research action. The Directorate of Science and Technology - specifically its Office of Research and Development (ORD) did not remain idle after Director McCone transferred the behavioral research function in 1962.

In ORD, Dr. Stephen Aldrich, a graduate of Amherst and Northwestern Medical School, took over the role that Morse Allen and then Sid Gottlieb had played before him. Aldrich had been the medical director of the Office of Scientific Intelligence back in the days when that office was jockeying with Morse Allen for control of ARTICHOKE, so he was no stranger to the programs. Under his leadership, ORD officials kept probing for ways to control human behavior, and they were doing so with space-age technology that made the days of MKULTRA look like the horse-and-buggy era. If man could get to the moon by the end of the 1960s, certainly the well-financed scientists of ORD could make a good shot at conquering inner space.

They brought their technology to bear on subjects like the electric stimulation of the brain. John Lilly had done extensive work in this field a decade earlier, before concluding that to maintain his integrity he must find another field. CIA men had no such qualms, however. They actively experimented with placing electrodes in the brain of animals and - probably - men. Then they used electric and radio signals to move their subjects around. The field went far beyond giving monkeys orgasms, as Lilly had done. In the CIA itself, Sid Gottlieb and the MKULTRA crew had made some preliminary studies of it. They started in 1960 by having a contractor search all the available literature, and then they had mapped out the parts of animals' brains that produced reactions when stimulated. By April 1961 the head of TSS was able to report "we now have a 'production capability' " in brain stimulation and "we are close to having debugged a prototype system whereby dogs can be guided along specific courses." Six months later, a CIA document noted, "The feasibility of remote control of activities in several species of animals has been demonstrated.... Special investigations and evaluations will be conducted toward the application of selected elements of these techniques to man." Another six months later, TSS officials had found a use for electric stimulation: this time putting electrodes in the brains of coldblooded animals - presumably reptiles. While much of the experimentation with dogs and cats was to find a way of wiring the animal and then directing it by remote control into, say, the office of the Soviet ambassador, this cold-blooded project was designed instead for the delivery of chemical and biological agents or for "executive action-type operations," according to a document. "Executive action" was the CIA's euphemism for assassination.

With the brain electrode technology at this level, Steve Aldrich and ORD took over the research function from TSS. What the ORD men found cannot be said, but the open literature would indicate that the field progressed considerably during the 1960s. Can the human brain be wired and controlled by a big enough computer? Aldrich certainly tried to find out.

Creating amnesia remained a "big goal" for the ORD researcher, states an ex-CIA man. Advances in brain surgery, such as the development of three-dimensional, "stereotaxic" techniques, made psychosurgery a much simpler matter and created the possibility that a precisely placed electrode probe could be used to cut the link between past memory and present recall. As for subjects to be used in behavioral experiments of this sort, the ex-CIA man states that ORD had access to prisoners in at least one American penal institution. A former Army doctor stationed at the Edgewood chemical laboratory states that the lab worked with CIA men to develop a drug that could be used to help program in new memories into the mind of an amnesic subject. How far did the Agency take this research? I don't know.

The men from ORD tried to create their own latter-day version of the Society for the Investigation of Human Ecology. Located outside Boston, it was called the Scientific Engineering Institute, and Agency officials had set it up originally in 1956 as a proprietary company to do research on radar and other technical matters that had nothing to do with human behavior. Its president, who says he was a "figurehead," was Dr. Edwin Land, the founder of Polaroid. In the early 1960s, ORD officials decided to bring it into the behavioral field and built a new wing to the Institute's modernistic building for the "life sciences." They hired a group of behavioral and medical scientists who were allowed to carry on their own independent research as long as it met Institute standards. These scientists were available to consult with frequent visitors from Washington, and they were encouraged to take long lunches in the Institute's dining room where they mixed with the physical scientists and brainstormed about virtually everything. One veteran recalls a colleague joking, "If you could find the natural radio frequency of a person's sphincter, you could make him run out of the room real fast." Turning serious, the veteran states the technique was "plausible," and he notes that many of the crazy ideas bandied about at lunch developed into concrete projects.

Some of these projects may have been worked on at the Institute's own several hundred-acre farm located in the Massachusetts countryside. But of the several dozen people contacted in an effort to find out what the Institute did, the most anyone would say about experiments at the farm was that one involved stimulating the pleasure centers of crows' brains in order to control their behavior. Presumably, ORD men did other things at their isolated rural lab.

Just as the MKULTRA program had been years ahead of the scientific community, ORD activities were similarly advanced. "We looked at the manipulation of genes," states one of the researchers. "We were interested in gene splintering. The rest of the world didn't ask until 1976 the type of questions we were facing in 1965.... Everybody was afraid of building the supersoldier who would take orders without questioning, like the kamikaze pilot. Creating a subservient society was not out of sight." Another Institute man describes the work of a colleague who bombarded bacteria with ultraviolet radiation in order to create deviant strains. ORD also sponsored work in parapsychology. Along with the military services, Agency officials wanted to know whether psychics could read minds or control them from afar (telepathy), if they could gain information about distant places or people (clairvoyance or remote viewing), if they could predict the future (precognition), or influence the movement of physical objects or even the human mind (photokinesis). The last could have incredibly destructive applications, if it worked. For instance, switches setting off nuclear bombs would have to be moved only a few inches to launch a holocaust. Or, enemy psychics, with minds honed to laser-beam sharpness, could launch attacks to burn out the brains of American nuclear scientists. Any or all of these techniques have numerous applications to the spy trade.

While ORD officials apparently left much of the drug work to Gottlieb, they could not keep their hands totally out of this field. In 1968 they set up a joint program, called Project OFTEN, with the Army Chemical Corps at Edgewood, Maryland to study the effects of various drugs on animals and humans. The Army helped the Agency put together a computerized data base for drug testing and supplied military volunteers for some of the experiments. In one case, with a particularly effective incapacitating agent, the Army arranged for inmate volunteers at the Holmesburg State Prison in Philadelphia. Project OFTEN had both offensive and defensive sides, according to an ORD man who described it in a memorandum. He cited as an example of what he and his coworkers hoped to find "a compound that could simulate a heart attack or a stroke in the targeted individual." In January 1973, just as Richard Helms was leaving the Agency and James Schlesinger was coming in, Project OFTEN was abruptly canceled.

What - if any - success the ORD men had in creating heart attacks or in any of their other behavioral experiments simply cannot be said. Like Sid Gottlieb, Steve Aldrich is not saying, and his colleagues seem even more closemouthed than Gottlieb's. In December 1977, having gotten wind of the ORD programs, I filed a Freedom of Information request for access to ORD files "on behavioral research, including but not limited to any research or operational activities related to bioelectrics, electric or radio stimulation of the brain, electronic destruction of memory, stereotaxic surgery, psychosurgery, hypnotism, parapsychology, radiation, microwaves, and ultrasonics." I also asked for documentation on behavioral testing in U.S. penal institutions, and I later added a request for all available files on amnesia. The Agency wrote back six months later that ORD had "identified 130 boxes (approximately 130 cubic feet) of material that are reasonably expected to contain behavioral research documents."

Considering that Admiral Turner and other CIA officials had tried to leave the impression with Congress and the public that behavioral research had almost all ended in 1963 with the phaseout of MKULTRA, this was an amazing admission. The sheer volume of material was staggering. This book is based on the 7 boxes of heavily censored MKULTRA financial records plus another 3 or so of ARTICHOKE documents, supplemented by interviews. It has taken me over a year, with significant research help, to digest this much smaller bulk. Clearly, greater resources than an individual writer can bring to bear will be needed to get to the bottom of the ORD programs.

A free society's best defense against unethical behavior modification is public disclosure and awareness. The more people understand consciousness-altering technology, the more likely they are to recognize its application, and the less likely it will be used. When behavioral research is carried out in secret, it can be turned against the government's enemies, both foreign and domestic. No matter how pure or defense-oriented the motives of the researchers, once the technology exists, the decision to use it is out of their hands. Who can doubt that if the Nixon administration or J. Edgar Hoover had had some foolproof way to control people, they would not have used the technique against their political foes, just as the CIA for years tried to use similar tactics overseas?

As with the Agency's secrets, it is now too late to put behavioral technology back in the box. Researchers are bound to keep making advances. The technology has already spread to our schools, prisons, and mental hospitals, not to mention the advertising community, and it has also been picked up by police forces around the world. Placing hoods over the heads of political prisoners - a modified form of sensory deprivation - has become a standard tactic around the world, from Northern Ireland to Chile. The Soviet Union has consistently used psychiatric treatment as an instrument of repression. Such methods violate basic human rights just as much as physical abuse, even if they leave no marks on the body.

Totalitarian regimes will probably continue, as they have in the past, to search secretly for ways to manipulate the mind, no matter what the United States does. The prospect of being able to control people seems too enticing for most tyrants to give up. Yet, we as a country can defend ourselves without sending our own scientists - mad or otherwise - into a hidden war that violates our basic ethical and constitutional principles. After all, we created the Nuremberg Code to show there were limits on scientific research and its application. Admittedly, American intelligence officials have violated our own standard, but the U.S. Government has now officially declared violations will no longer be permitted. The time has come for the United States to lead by example in voluntarily renouncing secret government behavioral research. Other countries might even follow suit, particularly if we were to propose an international agreement which provides them with a framework to do so.

Tampering with the mind is much too dangerous to be left to the spies. Nor should it be the exclusive province of the behavioral scientists, who have given us cause for suspicion. Take this statement by their most famous member, B. F. Skinner: "My image in some places is of a monster of some kind who wants to pull a string and manipulate people. Nothing could be further from the truth. People are manipulated; I just want them to be manipulated more effectively." Such notions are much more acceptable in prestigious circles than people tend to think: D. Ewen Cameron read papers about "depatterning" with electroshock before meetings of his fellow psychiatrists, and they elected him their president. Human behavior is so important that it must concern us all. The more vigilant we and our representatives are, the less chance we will be unwitting victims.

Notes 12

The reorganization of TSS was described in document #59, 26 July 1963, Report of the Inspection of MKULTRA and in interviews with Ray Cline, Herbert Scoville, and several other former CIA officials.

Richard Helms' recommendations for a new MKULTRA charter were described in document #450, 9 June, 1964, Sensitive Research Programs (MKULTRA).

Admiral Stansfield Turner's statement on the MKULTRA program was made before a joint session of the Kennedy subcommittee and the Senate Select Committee on Intelligence, August 3, 1977, pp. 4-8.

MKSEARCH programs and their origins in MKULTRA are described in documents #449, 8 April 1964, Revision of Project MKULTRA and #S-1-7, untitled, undated.

Dr. Edward Bennett's work is the subject of MKULTRA subprojects 104 and 143. See especially 143-23, 11 December 1962, Subject: MKULTRA Subproject 143. Other information on the CIA's economic sabotage program against Cuba came from interviews with Major General Edward Lansdale, Ray Cline, William Colby, Lincoln Gordon, Covey Oliver, Charles Meyer, Richard Goodwin, Roger Morris, several former CIA and State Department officials, and Cuban government officials.

The continued safehouse operation is MKSEARCH subproject 4. See especially S-12-1, bank statements and receipts of safehouse. The CIA's dealings with the Treasury Department over the Long committee's investigations of wiretaps are detailed in documents #451, 30 January 1967, A Report on a Series of Meetings with Department of the Treasury officials and #452, undated, Meeting with Department of Treasury Official.

The biological laboratory is the subject of MKULTRA subprojects 78 and 110 and MKSEARCH 2. See especially Documents 78-28, September 28, 1962, Subject: PM Support and Biological [deleted] and S-5-6, 8 September 1965, Subject: Hiring by Chief TSD/BB of [deleted], Former Staff Employee in a Consultant Capacity on an Agency Contract. The costs of the Fort Detrick operations came from p. 18 and p. 204 of the Church committee hearings on Unauthorized Storage of Toxic Agents September 16,17, and 18,1975. The description of TSS's procedures for dealing with biological weapons came from Document 78-28 (cited above) and document #509, undated (but clearly June 1975), Subject: Discussions of MKNAOMI with [deleted].

The chemical company subproiect is MKULTRA subproject 116 and MKSEARCH 5. See especially 116-57,30 January 1961, Subject: MKULTRA, Subproject 116; 116-62, October 28, 1960, shipping invoice- and 116-61,4 November 1960, Subject: MKULTRA Subproject 116. Also see James Moore's subproject, MKULTRA 52; especially 52-53, invoice # 3, 1125-009-1902, April 27, 1960.

James Hamilton's work is the subject of MKULTRA subprojects 124 and 140 and MKSEARCH Subproject 3. See especially 140-57, 6 May 1965, Subject: Behavioral Control and 140-83, 29 May 1963, Subject: MKULTRA Subproject 140.

Carl Pfeiffer's subprojects are MKULTRA 9, 26, 28, and 47 and MKSEARCH 7. See especially S-7-4, undated, Subject: Approval of Project [deleted].

Maitland Baldwin's Subprojects are MKULTRA 62 and MKSEARCH 1. See especially 62-2, undated [deleted] Special Budget and 62-3, undated, 1956, Subject: Re: Trip to [deleted], October 10-14, 1956.

Charles Geschickter's subprojects are MKULTRA 23, 35, and 45 and MKSEARCH 6. See especially 35-10, May 16, 1955, Subject- To provide for Agency-Sponsored Research Involving Covert Biological and Chemical Warfare; 45-78, undated, Research Proposal: 1960, 45-104 undated, Subject: Research Proposal: 1958-1959; 45-95, 26 January 1959, Continuation of MKULTRA, Subproject No.45; 45-104,21 January 1958, Continuation of MKULTRA, Subproject No.45; 45-52,8 February 1962, Continuation of MKULTRA, Subproject No. 45; S-13-7,13 August Subject, Approval of [deleted]; and S-13-9, 13 September 1967, Subject: Approval of [deleted]. See also Geschickter's testimony before the Kennedy subcommittee, September 20, 1977, pp. 44-49.

The lack of congressional or executive branch knowledge of CIA behavioral activities was mentioned on p. 386, Church Committee Report, Book I.

Amazon Natural Drug's CIA connection was described by an ex-ClA official and confirmed by the mother of another former Agency man. Several former employees described its activities in interviews.

Gottlieb's termination of MKSEARCH came from Document S-14-3 10 July 1972, Termination of MKSEARCH.

The destruction of MKULTRA documents was described in Document #419, 3 October, 1975, Subject: Destruction of Drug and Toxin Related Files and 460, 31 January, 1973, Subject: Project Files: (19511967).

The MKULTRA subprojects on electric stimulation of the brain are 106 and 142. See especially 106-1, undated, Subject: Proposal; 142-14, 22 May 1962, Subject: Project MKULTRA, Subproject No. 142; and document #76 (MKDELTA release), 21 April 1961, Subject: "Guided Animal" Studies.

The list of parapsychology goals was taken from an excellent article by John Wilhelm in the August 2, 1977 Washington Post: "Psychic Spying?"

Project OFTEN information was taken from document #455,6 May 1974, Subject: Project OFTEN and Memorandum for the Secretary of Defense from Deanne P. Siemer, September 20, 1977, Subject: Experimentation Programs Conducted by the Department of Defense That Had CIA Sponsorship or Participation and That Involved the Administration to Human Subjects of Drugs Intended for Mind-control or

Behavior-modification Purposes.

The quote from B. F. Skinner was taken from Peter Schrag's book, Mind Control (New York: Pantheon, 1978) p. 10.

Footnotes 12

1. At 1977 Senate hearings, CIA Director Stansfield Turner summed up some of MKULTRA's accomplishments over its 11-year existence: The program contracted out work to 80 institutions, which included 44 colleges or universities, 15 research facilities or private companies, 12 hospitals or clinics, and 3 penal institutions. I estimate that MKULTRA cost the taxpayers somewhere in the neighborhood of $10 million.
2. This economic sabotage program started in 1961, and the chain of command "ran up to the President," according to Kennedy adviser Richard Goodwin. On the CIA side, Agency Director John McCone "was very strong on it," says his former deputy Ray Cline. Cline notes that McCone had the standing orders to all CIA stations abroad rewritten to include "a sentence or two" authorizing a continuing program to disrupt the Cuban economy. Cuba's trade thus became a standing target for Agency operators, and with the authority on the books, CIA officials apparently never went back to the White House for renewed approval after Kennedy died, in Cline's opinion. Three former Assistant Secretaries of State in the Johnson and Nixon administrations say the sabotage, which included everything from driving down the price of Cuban sugar to tampering with cane-cutting equipment, was not brought to their attention. Former CIA Director William Colby states that the Agency finally stopped the economic sabotage program in the early 1970s. Cuban government officials counter that CIA agents were still working to create epidemics among Cuban cattle in 1973 and that as of spring 1978, Agency men were committing acts of sabotage against cargo destined for Cuba.
3. In 1967 a Senate committee chaired by Senator Edward Long was inquiring into wiretapping by government agencies, including the Narcotics Bureau. The Commissioner of Narcotics, then Harry Giordano told a senior TSS man - almost certainly Gottlieb - that if CIA officials were "concerned" about its dealings with the Bureau involving the safehouses coming out during the hearings, the most "helpful thing" they could do would be to "turn the Long committee off." How the CIA men reacted to this not very subtle blackmail attempt is unclear from the documents, but what does come out is that the TSS man and another top-level CIA officer misled and lied to the top echelon of the Treasury Department (the Narcotics Bureau's parent organization) about the safehouses and how they were used.
4. James Moore of the University of Delaware, who also produced carbamates when he was not seeking the magic mushroom, served at times as an intermediary between the industrialist and the CIA.
5. During the late 1960s and early 1970s, it seemed that every radical on the West Coast was saying that the CIA was up to strange things in behavior modification at Vacaville. Like many of yesterday's conspiracy theories, this one turned out to be true.
6. Geschickter was an extremely important TSS asset with connections in high places. In 1955 he convinced Agency officials to contribute $375,000 in secret funds toward the construction of a new research building at Georgetown University Hospital. (Since this money seemed to be coming from private sources, unwitting Federal bureaucrats doubled it under the matching grant program for hospital construction.) The Agency men had a clear understanding with Geschickter that in return for their contribution, he would make sure they received use of one-sixth of the beds and total space in the facility for their own "hospital safehouse." They then would have a ready source of "human patients and volunteers for experimental use," according to a CIA document, and the research program in the building would provide cover for up to three TSS staff members. Allen Dulles personally approved the contribution and then, to make sure, he took it to President Eisenhower's special committee to review covert operations. The committee also gave its assent, with the understanding that Geschickter could provide "a reasonable expectation" that the Agency would indeed have use of the space he promised. He obviously did, because the CIA money was forthcoming. (This, incidentally, was the only time in a whole quarter-century of Agency behavior-control activities when the documents show that CIA officials went to the White House for approval of anything. The Church committee found no evidence that either the executive branch or Congress was informed of the programs.)
7. In 1967, after Ramparts magazine exposed secret CIA funding of the National Student Association and numerous nonprofit organizations, President Johnson forbade CIA support of foundations or educational institutions. Inside the Agency there was no notion that this order meant ending relationships, such as the one with Geschickter. In his case, the agile CIA men simply transferred the funding from the foundation to a private company, of which his son was the secretary-treasurer.
8. Lying to Congress followed the pattern of lying to the press that some MKULTRA veterans adopted after the first revelations came out. For example, former Human Ecology Society director James Monroe told The New York Times on August 2, 1977 that "only about 25 to 30 percent" of the Society's budget came from the CIA - a statement he knew to be false since the actual figure was well over 90 percent. His untruth allowed some other grantees to claim that their particular project was funded out of the non-Agency part of the Society.

Entheogenic Mysticism: A Jamesian Assessment

by

G.William Barnard

original text: http://www.neip.info/upd_blob/0000/446.pdf
backup source: http://www.psilosophy.info/resources/446.pdf

In my anthropology of religion course "Magic, Myth, and Religion," I devote a substantial amount of time to a discussion of the centrality of non-ordinary states of consciousness in the religious life of many cultures. During this section of the course, I focus on how individuals in numerous cultures use fasting, dancing, drumming, chanting, breathing exercises, and so on, as ways to facilitate contact with various spiritual realities. In this section of the course, I also discuss the ways in which sacred (i.e., consciousness altering) plants are ritually ingested by individuals in several cultures, especially in the Americas, in an attempt to open themselves to spiritual dimensions of existence. My students are typically quite fascinated, for instance, to learn about the Huichol people's annual peyote pilgrimage, or the role that ayahuasca plays within the context of the Santo Daime tradition (a Brazilian syncretistic new religious movement), or the centrality of the San Pedro cactus in coastal Peruvian curanderismo. However, after my students have been exposed to numerous detailed accounts of the visionary/mystical experiences that practitioners in these traditions have had after ingesting these sacred substances, almost inevitably some student will ask a question that goes something like the following: "Aren't all of these so called visionary/mystical experiences merely hallucinations caused by taking drugs?"

As a professor, I think that it is crucial to address this question. After all, at least on the face of it, it is understandable why students would raise such questions. Given the taken-for-granted "scientific" (i.e., materialistic and positivistic) perspective that most of my students have internalized, it is easy to see how they would interpret the dramatic epiphanies produced by ingesting different species of sacred plants as simply delusory hallucinations, as nothing more than the result of the malfunctioning neuro-chemical activity within the brains of those who have taken these psychoactive substances. Given this set of presuppositions, it can be very difficult for my students to comprehend why we should take seriously the claims made by those within these religious traditions who advocate the ritual use of entheogens (i.e., substances that "generate god or spirit within").

Having internalized the message that all drugs are psychologically and physiologically harmful, socially destructive, and addictive (with the significant exception of socially approved versions of drugs, such as alcohol, Prozac, nicotine, and caffeine) it can be tough for my students to swallow (so to speak) that within many cultures in the Americas, mind-altering substances, such as peyote, psilocybin mushrooms, and ayahuasca, are seen as gifts from the gods, are valued as powerful medicines for the body and the mind, are taken in order to nurture harmonious relationships with others, and are deeply revered as the source of not only their music and art, but also their most fundamental religious beliefs and practices. It can be hard for my students to imagine that people within these cultures would claim, repeatedly, fervently, that rejection of this visionary knowledge is, quite simply, a form of insanity. It can take quite a lot of persuasive evidence on my part for them to begin to accept even the possibility that entheogenic substances are non-addictive, that there is no evidence that they are psychologically or physiologically harmful if used within structured ritual contexts, and that they have been safely consumed by human beings for possibly tens of thousands of years.

My guess is that many of you in this audience might well sympathize with my students' reluctance to take entheogenic mystical and visionary experiences as seriously as those that are catalyzed by non-entheogenic "spiritual technologies," such as meditation, drumming, dancing, fasting, prayer, and so on. It is just so easy to think that the alterations of consciousness that are associated with the ingestion of peyote, psilocybin, and ayahuasca are merely hallucinations.

As I often point out to my students, however, this negative assessment of the experiences of those who take entheogens within a religious context is rooted in a taken-for-granted understanding of the relationship between the brain and consciousness. As the American philosopher and psychologist William James points out in an essay published in 1898 ("Human Immortality: Two Supposed Objections to the Doctrine"), the standard materialistic understanding of the relationship between the brain and consciousness assumes that the brain itself produces the "stuff" of consciousness in much the same way that steam is produced by a kettle, or light is produced by an electric circuit. From this perspective, which James calls the "productive" theory of consciousness, consciousness is created by the various complex chemical interactions that take place inside the brain.[1]

If we assume that the neurochemical activity of the brain *produces* our states of consciousness, then it makes sense to also assume that if a people eat psilocybin mushrooms or peyote buttons, or drink ayahuasca, that the so-called mystical experiences or religious visions that they describe are nothing more than the hallucinatory byproducts of cerebral malfunctions caused by the chemical activity of these substances. However, what many of us may not realize is that, from the perspective of the productive theory of consciousness, *every* mystical or religious experience is hallucinatory, they too are nothing more than mental aberrations caused by the misfirings of neurons in the brain. From the perspective of the productive theory of consciousness, the only real world is the world that is perceived through the senses. By definition, therefore, if you are having extra-sensory perceptions, then there is simply something wrong with your cerebral circuitry. From the perspective of the productive theory of consciousness, the exalted mystical experiences of Teresa of Avila, for instance, have exactly the same status as the peyote visions of the headman in a Native American Church: *both* are hallucinations generated by pathological activity of the brain.

In James' essay, however, he points out that there is an alternative way to understand the relationship between the brain and consciousness (and therefore, an alternative way to understand the genesis of mystical and religious experiences). It is also possible, James writes, that consciousness pre-exists the brain, and that the role of the brain is to mold that pre-existent consciousness into various forms. Seen from this perspective, the brain's task would be to receive and transmit limited forms of this consciousness in much the same way as, to use an anachronistic example, a radio receives portions of pre-existing radio waves and then transmits them through the air as sound waves. James refers to this relationship between the brain and a pre-existing larger consciousness as the "transmissive function," and points out that this transmissive function is operative "in the case of a colored glass, a prism, or a refracting lens," when "the energy of light, no matter how produced, is by the glass shifted and limited in color, and by the lens or prism determined to a certain path and shape."[2]

James insists that it is just as logical and scientific to postulate that the brain receives, limits, directs, and shapes pre-existent states of awareness as it is to postulate that the brain produces different states of consciousness. *Both* theories take for granted that there is a relationship between the brain and consciousness. According to both theories, an alteration in the neurochemical interactions of the brain corresponds to an alteration in consciousness. What is not so self evident, however, is that the neurochemical interactions of the brain *cause* the corresponding alterations of consciousness. What is just as likely, at least from a philosophical perspective, is that alterations in the brain chemistry "open the door" to levels of consciousness that were previously inaccessible. (Another option is that alterations within the pre-existing field of consciousness are what cause the shifts in the neurochemical activity of the brain. This way of understanding the relationship between consciousness and the brain is how many cultures would, at least tacitly, explain states of mediumship where culturally endorsed spiritual beings are said to speak and act in-and-through the willing body of a religious practitioner. This option is also, more prosaically, what many of us tacitly assume takes place when we believe that our intentions, thoughts and feelings, i.e., our states of consciousness, direct the activity of our physical body.)

James emphasizes that "the theory of production is ... not a jot more simple or credible in itself than any other conceivable theory. It is only a little more popular."[3] Indeed, James claims that, in some ways, the transmissive function has certain theoretical advantages over its more popular competitor. If the transmissive theory of consciousness is accepted, then consciousness "does not have to be generated *de novo* in a vast number of places. It exists already, behind the scenes," intimately connected with this world.[4]

James points out another apparent advantage of the transmissive theory of consciousness over the productive theory: the transmissive theory is able to account coherently for a wide variety of phenomena that the productive theory has difficulty explaining. Such phenomena as "religious conversions, providential leadings in answer to prayer, instantaneous healings, premonitions, apparitions at time of death, clairvoyant visions or impressions, and the whole range of mediumistic capacities" are all more easily understood with the transmissive theory of consciousness.[5] This is so, as James notes, because the productive theory of consciousness is intimately linked with sense perceptions, but in the case of many of these less orthodox phenomena, "it is often hard to see where the sense-organs can come in."[6] For instance, as James mentions, a medium might have knowledge of the personal life of his or her client that would be impossible to obtain from the senses, or a person might see a vision of someone who, hundreds of miles away, was at that very moment dying. James points out that it is difficult to see how the productive theory of consciousness can explain how these types of knowledge were produced within a single brain. But if the transmissive theory is accepted, the answer is apparent: "they don't have to be 'produced,' - they exist ready-made in the transcendental world," so that in "cases of conversion, providential leadings, sudden mental healings, etc. it seems to the subjects themselves ... as if a power from without, quite different from the ordinary action of the senses or of the sense-led mind, came into their life, as if [their life] suddenly opened into that greater life in which it has its source."[7]

James believes that psychologists and philosophers choose between the transmissive theory and the productive theory of consciousness based on what type of world they are willing or able to accept (i.e., based on their metaphysical assumptions). If these thinkers are limited to a purely materialistic or naturalistic perspective, then the productive function of the brain will be all that they will acknowledge as valid. If, however, these thinkers assume that "the whole universe of material things ... [is] a surface-veil of phenomena, hiding and keeping back the world of genuine realities," if they believe that life is similar to Percy Shelly's words in his poem "Adonais," in which "Life, like a dome of many-colored glass, Stains the white radiance of eternity," then they will acknowledge that the transmissive function of the brain is a legitimate possibility.[8] Utilizing Shelly's metaphor, James theorizes that our brains might indeed be places in this "dome" where the "beams" of consciousness could most easily enter into our realm of experience. In that case, as the "white radiance" of that larger pre-existing consciousness enters our brains, then a type of refracting and "staining and distortion" would naturally occur, shaping that greater consciousness into the personal, imperfect, and unique forms that consciousness takes inside "our finite individualities here below."[9]

Drawing upon the work of the French philosopher Henri Bergson, Aldous Huxley offers a strikingly similar explanation of the relationship between consciousness and the brain in his 1954 book *The Doors of Perception*. Huxley points out that according to Bergson, each of us is, under the surface of our normal everyday awareness, connected to, and potentially aware of, the entire universe. We are normally, however, cut off from this "Mind at Large" because our brain screens or filters out the vast majority of what we are potentially able to perceive in order to protect us from being overwhelmed and confused by this almost infinite amount of information. Our brains, therefore, act in essence as biological reducing valves. Seen from this perspective, the primary function of our brain is not so much to *produce* consciousness as it is to limit the torrential flow of information that is pouring into us, moment by moment, to the bare minimum we need to survive.

Drawing upon his own experiences taking mescaline (the active chemical component of peyote and San Pedro), Huxley postulates that perhaps the ingestion of sacred substances (or conversely, various spiritual disciplines) "impair the efficiency of the cerebral reducing valve," resulting in an influx of extrasensory knowledge as well as perceptions of a world of visionary beauty.[10] He theorizes that perhaps entheogens (as well as, at least implicitly, "spiritual technologies," such as chanting, fasting, meditation, contemplation, ecstatic dance, and so on) allow us to tap into "previously untapped levels of our own mind ... and previously unrecognized dimensions or levels of reality"; seen in this way, these sacred substances do not "distort reality," but rather, "disclose dimensions or levels of existence that are otherwise screened by the rational ego."[11]

While many, if not most, academics and scientists might scoff at the alternative understanding of the relationship between the brain and consciousness that is proposed by James, Bergson, and Huxley, there have been a handful of current theorists who have taken this non-mainstream perspective quite seriously. For instance, George Wald, a Nobel Prize winning physiologist from Harvard points out:

> There is no way of knowing whether the brain contains consciousness in the sense that it is producing it or whether it is simply a reception and transmission mechanism which, as Bergson has argued, has the function of selection and realization of conscious images and not the production of such

> images. As a neuroscientist, one can only intervene in the brain and record whether the intervention in particular parts of the brain results in the evocation or abolishment of conscious experience.[12]

As Wald notes, simply because there is a correspondence between brain activity and states of consciousness does not indicate that those states were produced by the brain, or somehow localized within it. Suppose, for example, that we compare the brain to a television set. There is, apparently, a one-to-one relationship between the electrical and mechanical activity of the television set and the programs that are appearing on the screen. But no one ever claims that the program that is appearing on the screen has been *produced* by the television. Instead, a television set receives, limits, directs, and shapes pre-existing electro-magnetic signals of various frequencies into the programs that we watch on the screen. Similarly, as Wald notes, if we "pull a transistor out of [our] T.V. set and it no longer works," we would not (or at least should not) "conclude that the transistor is the source of the program," anymore than we are forced to conclude that the brain is what produces consciousness simply because when a person's brain has been damaged by a severe organic illness or trauma, her or his cognitive abilities are severely impaired.[13]

Seen from this perspective, we can theorize that entheogens are simply a way to "change the channel" of the "television" of the brain so that it can receive information from other (and in this case, "spiritual") dimensions of reality. If we are willing to accept this alternate way of understanding the relationship between the activity of the brain and changes in our states of consciousness (at least as a philosophical possibility), then the mystical experiences that take place after ingesting various entheogens can be understood as potentially valid visionary/mystical experiences, and not necessarily as delusive psychopathological hallucinations.

In *The Varieties of Religious Experience*, James cautions that it is crucial that we question our frequent tendency to assume that any insight that arises in conjunction with a powerful alteration of our physiology is invalid. As he points out, we would never dismiss the validity of a scientific insight simply because it arose during a fever. Similarly, we should not dismiss the insights of a mystic or visionary simply because their body's chemistry has shifted in certain respects. In much the same way, therefore, given the assumption that the visions or insights that arise in conjunction with drinking ayahuasca, or eating peyote are said to arise from superconscious dimensions of reality, it is quite possible that they may in actuality be *more* truthful and beneficial to our well being than the perceptions and beliefs that emerge from our normal waking state of consciousness. They should not be prematurely dismissed simply because of a bias in favor of the state of consciousness that our culture assumes to be normative.

Similarly, as scholars of religion, we might need to question the assumption that the mystical experiences that take place within more well-known mystical traditions such as, Christian, Jewish, Islamic, Hindu, Buddhist, and Taoist forms of mysticism, are inherently superior to the mystical insights that are obtained via the ingestion of entheogens. But why should we make this assumption? What are the criteria by which we assess whether mystical experiences (whether entheogenically-inspired or not) are valid and/or valuable? Once again, James's perspective offers us a way to begin to answer some of these important questions.

In the *Varieties*, James offers the three-fold proto-pragmatic criteria of "immediate luminosity," "philosophical reasonableness," and "moral helpfulness" to assess the validity and value of religious/mystical experiences. "Immediate luminosity" is the criterion that encourages us to take seriously the experiential component of a religious state of mind - its immediate force, its raw voltage, its direct, tangible feeling. "Philosophical reasonableness" is the criterion that we can use to assess whether a religious state of mind can be shown to be reasonable and logical by virtue of its place within an articulate and defensible philosophical system of beliefs. Finally, "moral helpfulness" is demonstrated when and if a religious state of mind can be shown to initiate, on the whole and over the long run, positive consequences for the individual and/or the community. These criteria are not mutually exclusive, but rather interact with, and depend upon, each other. Furthermore, this evaluative procedure is not a matter of precisely weighing the percentage of each criterion's importance, but instead, is a holistic, cumulative process. As James emphasizes, the final test for assessing a state of mind is not the individual "score" of each of these criteria, but rather it is their cumulative weight, the way they work as a whole and on the whole.[14]

What I would like to do during the remainder of the time that we have together is to apply these three criteria to a specific test case to see whether they might help us to begin the difficult, yet important, task of determining whether the mystical experiences found in an entheogenic tradition are as inspiring, trustworthy, and transformative as those found in other, more well known, mystical traditions.

For the purposes of our discussion, I have chosen to focus on the Santo Daime tradition. After giving a brief overview of the history and major beliefs and practices of this Brazilian entheogenically-based religious movement, I will examine several mystical narratives arising from within the tradition to illustrate the extent to which these entheogenically-inspired experiences match up with the power, immediacy, and luminosity of mystical experiences found in other non-entheogenic traditions (i.e., I will attempt to assess their immediate luminosity, James' first criterion). I will then briefly describe some of the central (albeit often implicit) philosophical understandings that undergird the religious teachings of the Santo Daime tradition, in order to explore whether their depth, complexity, and coherence equals that of other mystical traditions (i.e., I will attempt to assess their philosophical reasonableness, James' second criterion). And finally, I will offer various accounts of the personal and social transformative effects of taking ayahuasca within the ritual context of the Santo Daime tradition, as a way to investigate the extent to which this entheogenic tradition can be at least as personally and socially transformative as other more well known mystical traditions (i.e., I will attempt to assess their moral helpfulness, James' third criterion).

The Santo Daime religious movement began late in the second decade of the twentieth century. Raimundo Irineu Serra, a seven foot tall black man working as a border guard deep in the Amazonian rainforest at the border between Brazil and Peru became interested in the use of ayahuasca in the tribal ceremonies of the people of the area. Ayahuasca is a tea created from boiling together in water a vine (*Banisteriopsis caapi*) and the leaves from a bush (*Psychotria viridis*). Neither the vine nor the leaf, separately, is psychoactive. It is only when they are combined (especially in a ritualistic context) that an entheogen is produced.

Irineu Serra, after drinking ayahausca, had a powerful experience in which he claimed that the Spirit of the Moon revealed herself to him as the Rainha da Floresta, the Queen of the Forest. Later identified as the Virgin Mary, this sacred Being told Irineu that he had a special mission on earth: to establish a new religious movement called the Santo (Holy) Daime. (It can be said, therefore, that the entire tradition of the Santo Daime itself arose from an entheogenically inspired experience.)

Within this new context the sacramental tea was also given a new name, i.e., the "Daime," a word that comes from the Portuguese verb "dar": to give. It is linked to invocations that are frequently present during Santo Daime rituals: *dai-me amor, dai-me luz, dai-me forca* ("give me love, give me light, give me strength"). Within the Santo Daime tradition, the Daime is understood to be a sacrament that embodies the consciousness of a vastly intelligent and compassionate divine Being, a Being that, for Santo Daime practitioners, is equated with both Christ and the Holy Spirit, a Being who, in the words of one of the leaders of the movement, "incarnates in order to provide teaching, comfort, healing, and spiritual evolution to those" who take it within themselves as a liquid form of communion, a Being who opens a "gateway to other dimensions where other Beings reside."[15]

Mestre Irineu ("Master Irineu") as he was eventually called by his followers, gradually became well known as a powerful healer, visionary and spiritual teacher. In 1940, he established the first Santo Daime center in the town of Rio Branco, Brazil. Over time, complex and highly structured rituals developed that centered on taking the Daime as a sacrament and thus the shape of the Santo Daime tradition as we know it today began to emerge - a religion that although rooted in Christianity, also incorporates within itself elements of native South American spirituality, as well as aspects of African religiosity and Spiritism.

With the death of Mestre Irineu in 1971, the group split into several different branches. The most well known "line" of the Santo Daime tradition is that which centered around the charismatic leadership of Sebastiao Mota de Melo, later known as Padrinho Sebastiao.

Sebastiao Mota de Melo was born in 1920 and grew up in the middle of the Amazon rainforest. He made his living as a rubber tapper and builder of dugout canoes, but spiritually, he became known from a relatively early age as a powerful visionary and mediumistic healer of the impoverished people of that area. At the age of 38, following the guidance of one of the beings that he frequently incorporated in his mediumistic sessions, Padrinho Sebastiao traveled with his family in 1958 to Rio Branco. He had been suffering for several years from a fatal liver disease, and in hopes of a cure, he approached Mestre Irineu.

After taking the Daime, Padrinho Sebastiao had a series of powerful visionary experiences. In one of these experiences, he watched, from outside his body, as two resplendently beautiful beings took out his skeleton and abdominal organs from his body, without any pain, all the while vibrating his body, rocking it from side by side. These beings then used a hook that "opened, separated, and extracted" from his abdominal organs "three nailsized insects" which the beings of light claimed were responsible for Padrinho Sebastiao's illness.[16] In Sebastiao's account of this experience, he reports the following: "[the being] who had been seated next to my prostrate body, which was still stretched out on the floor, came very close to me and said, 'Here it is! What was killing you were these three insects, but now you will not die from them any more.' Then they closed my body. ... I healed, like a child."[17]

Padrinho Sebastiao was completely cured after this experience and, not surprisingly, he decided to become one of Mestre Irineu's followers. They quickly became very close, and with permission from Mestre Irineu, Padrinho Sebastiao set up a Santo Daime center of his own outside of Rio Branco. After Mestre Irineu's death, the community that had grown around Padrinho Sebastiao continued to flourish. But in the late 1970's he began to receive inner guidance to leave this location. Therefore, in 1980, Padrinho Sebastiao, his family, and about 100 followers left the Rio Branco area, with almost no material resources, and relocated deep in the rainforest at a site called Rio do Ouro. After three years of hard work, building houses, clearing and cultivating land, enduring sickness and hardship, a private landowner turned up, claiming his right to the land. Not wanting any trouble and trusting his inner guidance, the Santo Daime members left Rio do Ouro, and during the years of 1983-84, about 300 members settled in what came to be known as Céu do Mapiá (Heaven of Mapiá), located even deeper within the rainforest, on the banks of the Mapia river.

Soon afterwards, affiliated Santo Daime centers were set up in major Brazilian cities. These centers attracted many new members, but they also drew attention to the movement. A commission of army officials, university teachers, psychiatrists, psychologists, doctors and others was appointed to study the use of the Daime and visited Céu do Mapia in 1984. A similar commission had already visited the Rio do Ouro community in 1982. Both of these commissions wrote a report to the authorities that concluded that no negative psychological or social effects were linked to the ritual use of ayahuasca. Nonetheless, the Brazilian government decided to ban the use of ayahuasca in 1985. Due to the uproar that this decision created, another commission was put together in 1986. Eventually, after a careful investigation, the commission once again made a positive assessment of the Santo Daime tradition (as well as other traditions that used ayahuasca in ritual contexts), and the ban against ayahuasca was legally removed in Brazil in 1986.

After the death of Padrinho Sebastiao in 1990, one of his sons, Alfredo Mota de Melo, now called Padrinho Alfredo, took over the leadership of the movement. With his blessings, Santo Daime centers were started all around the world, particularly in Europe, Japan, and the United States.

What participants in all of these centers share is the desire to meet regularly in order to drink Daime collectively as a sacrament. During all of the rituals (or "works," as they are called) of the Santo Daime, participants gather together (men on one side, women on the other) around a central altar table and then sing (often for hours, with great reverence and devotion) collections of simple, yet hauntingly beautiful hymns that were originally "given" from the spiritual world to the more advanced members of the movement. According to the Santo Daime practitioners, praying and praising God together musically, with great purity and focus, accompanied by the rhythmic shaking of maracás, generates a powerful current of transformative spiritual energy and creates an uplifting, harmonious environment that is conducive to profound inner communion with the spiritual world and with the numerous beings that are said to exist there.

The powerful visionary/mystical experiences that individuals have during the Santo Daime works are called "miracaos." Like classical mystical experiences, these miracaos are said to be exceedingly difficult to describe, at least with any degree of adequacy, but many of the experiences that *are* shared manage to be quite evocative. For instance, one Santo Daime practitioner describes his experiences in the following way:

> "During my years of taking the Holy Daime, perhaps what stands out the most is feeling this incredibly powerful divine force working within me, with so much compassion and wisdom, clearing my body, mind, and energy field of anything that stands in the way of how this Light and

Love wants to express itself in and through me."

He goes on to note: "Another way in which I frequently experience the Daime working within me is that I will feel that I have been lifted, almost bodily, into another dimension of reality, one that is always present but that is normally hidden from my sight. From within this higher vibratory level of existence, I'll frequently see wave after wave of divine beauty with my eyes closed, visions that effortlessly flower within me as radiant, living, blossoming, geometric patterns of color, as profoundly significant manifestations of God's abundant, joyous, and exuberant creativity. And if my eyes are open, I'll look around me, and while I'm not physically seeing anything different, nonetheless somehow everything is brighter, absolutely perfect, transfigured, just shimmering with God's presence and Light."

Continuing, this practitioner adds: "I also remember one time, at the height of one of these moments, when we were all singing hymns together in the salao [the room where the works take place] and I was filled with so much ecstasy. I knew then, with this awestruck certainty, that all of us in that room were Christ, fully Christ, manifesting himself within us, as us. I could see that we were absolutely filled with divine glory, and that it was pouring through us. We were all singing together with such love, as this golden, radiantly beautiful Light shone within us and around us, Light that was offered as a gift to the entire world. One of my Daime brothers looked at me, just at that moment, and his eyes were really bright. I knew, somehow, that he was sharing this experience with me. He reached over, gave me this wonderful hug and said: 'Remember this, don't forget this.' And I never have."[18]

Another Santo Daime practitioner shared what she experienced the first time that she took the Daime: "I have to begin by saying what did *not* happen - since so many of my feared expectations, even about how I would *physically* be able to handle the Santo Daime, did not manifest. I was prepared perhaps to regurgitate it right back up - to vomit the murky brown, intensely bitter, distinctive-tasting drink. I was prepared perhaps to undergo one continuous state of nausea and/or emotional turmoil throughout my whole time under the influence of Daime and to end up flat on my back throughout the whole experience - or perhaps to be so completely freaked out that I'd simply want to flee the scene altogether. What I was *not* prepared for, right after taking my initial, partial shot glass of Santo Daime, was the sweetness of the experience - the way in which I so easily surrendered to the slow, thick, woozy feeling of the Daime's takeover of my physical being - the way that I so easily yielded to the pull of the Daime, the way that I was taken down the rabbit hole of an inner world that seemed both foreign and familiar to me, both intricately detailed and vast, both intensely personal and universal."

Continuing her account of her first experience with the Santo Daime, this woman goes on to say: "One of my defining and ongoing experiences of Santo Daime during that first encounter was the way in which I became essentially pinned in my seat, held bolt upright and extremely still - again as though not of my own volition, but due to the force of the current that was flowing within me. I was able to sit for hours at a time, literally held in place, serenely cross-legged in the blissful posture of a yogini in samadhi. As this seeming physical paralysis would take over, I was also made to understand (in the subtle ways that the Daime was always guiding and instructing me) that this bodily stillness was essential for my inner learning and deepening - that this was how the Daime needed to do her work within me. I would be sitting so deeply indrawn and completely at peace, while simultaneously I would be aware of the lively, even at times riotous, momentum of the singing and rattling that was filling the room. At times there would be a cacophony of other things also happening. For instance, I would be wrenchingly aware of this or that person (or several people) loudly weeping, undergoing some deeply personal, emotional clearing. Or I would be aware of this or that person physically purging into one of the buckets that were set just outside of the open door."

She added: "Although I have experienced in meditation before the sensation of being glued upright and still in my seat, as though it would take a great force of personal will to move even so much as a finger (even if I had wanted to!), I have never experienced such a sustained and internally directed period of time with such deep inner rapture and peace. It was as though I was the center around which everything was spiraling - the spiritual core at the heart of the world of matter, the prism of Light in and through which the unfolding, divine play of Consciousness itself was arising and subsiding, manifesting and dissolving the world of form and illusion. Time after time, any fear or question about what was happening to me that would momentarily surface was profoundly met and resolved. I came to understand at a level beyond mere mental comprehension that only what is *not* real can ever die, that only what is illusion - the egoic structure, defended being, belief in limitation, suffering based on ignorance and darkness, and so on - can ever die. Amazing insights about the unified nature of Consciousness and matter as well as specific directives about my personal life mission spontaneously arose: everything was happening in such harmony and perfection."[19]

These two accounts seem to match up well with many, if not most, of the classical narratives of mystical experiences that can be found within more well-known mystical traditions. I would therefore suggest that in terms of James's three criteria, these experiences clearly manifest the deeply felt, undeniably powerful impact of the criterion of "immediate luminosity."

What is not perhaps quite as clear, at least at this moment, is whether these experiences live up to the other two criteria. However, if we look carefully at the Santo Daime tradition, it is possible to see the "philosophical reasonableness" of this religious movement manifesting itself in and through its rich and multifaceted, albeit primarily implicit, set of religious teachings. Within the Santo Daime tradition, some of the most profound teachings are said to arise directly within each individual in-and-through the miracaos. Teachings within the Santo Daime tradition also take more public and concrete form within the revealed hymns that serve as the musical heart of the movement, as well as via spontaneous talks given by advanced practitioners during the context of the ritual works.

It is, of course, impossible within the very limited time that we have available today for me to give anything more than a brief glimpse of the range and depth of these teachings, but perhaps this task can be made easier by drawing upon some terse, yet eloquent, reflections on the central tenets of the tradition that have been written by a handful of the more experienced and articulate members within the movement. For instance, in the preface to *Forest of Visions*, one of the two books written about the Santo Daime tradition in the English language, Jonathan Goldman, an Oregon-based long time practitioner of the movement, shares some of his insights into the metaphysical assumptions that undergird the Santo Daime religious tradition.

According to Goldman, it is understood within the Santo Daime community that Jesus Christ "implanted a conscious seed in this world by his life and death. This was his mission: to initiate the vast change in human consciousness that is now beginning to come to fruition."[20] With Jesus' death, this "living matrix of consciousness," this "organizing principle of humanity's awakening" realized the distortions that would inevitably come to the teachings of the Christ and therefore chose to enter the rain forest, embodying itself in the jagube vine and the rainha leaf. However, as Goldman goes on to say, this superconscious being "through the Holy Daime ... is [currently] calling to Itself, one by one, the many souls who are ready to rapidly awaken the seed that Jesus planted, the Christ Consciousness in themselves."[21]

According to Goldman, this "direct experience of God" is the "birthright of all humans."[22] He goes on to suggest: "The Daime Path is laid out for each of us who is drawn to it, to walk and evolve as we go, at an accelerated, but distinctly individual, pace."[23] Goldman argues that the Daime is a type of spiritual "'short cut,' a very intense, demanding path to which people whose souls are ready to take a huge evolutionary leap are drawn, people who require a very deep cleansing and healing to take this leap, and who have the motivation to find the courage to follow their soul's urging."[24] Goldman claims:

> The Holy Daime Path is an authentic mystery school. There are levels of knowledge, stages of initiation that one passes through in one's program of rapid evolution... . The job of the initiate is to show up, drink Daime, work on the earth to live the teachings ... love God, love the earth, love all beings in God's creation, including yourself, love and respect your brothers and sisters, accept the truth of your own divinity and of your own faults, learn to embody forgiveness and mercy, and gain the hard won humility that comes from meeting a Divine force head on.[XXV]

Padrinho Alex Polari, another elder within the Santo Daime tradition, writes in *Forest of Visions*: "The Holy Daime is not for everyone. The rituals of the Daime are not meant to be an 'experience,' but rather to provide a chance to interact intimately with a Divine Being of unimaginable intelligence, compassion, clarity, and spiritual power."[26] He goes on to say: "The drink per se is the vehicle, the sacrament. Its ingestion reorganizes our organic, neurochemical, and energetic foundation, adjusting us to spiritual reality and its multiple meanings."[27] According to Polari: "Those who learn to work and receive this light consciousness synchronize themselves to higher plains of pure cosmic effervescence that penetrates the astral plane of our planet. As we drink from [this] spring of immortality, we operate through the patterned matrix made by all the ... beings of the universe."[28]

I think that while this exceedingly terse depiction of some of the central philosophical understandings of the Santo Daime tradition may leave some of you wanting to know more (and perhaps others of you glad that you do not), it is perhaps safe to say that this religious tradition possesses an intriguing, multi-layered, complex, and coherent set of beliefs and that, therefore, we can also ascertain that it fulfills "philosophical reasonableness," the second of James's criteria.

As for the third and final of James's criteria, i.e., "moral helpfulness," I would like to suggest that one of the most important reasons why individuals become members of the Santo Daime tradition and continue to engage in this difficult and demanding path of inner purification is not primarily due to the depth of the religious understandings within this path, or even because of the profound mystical and visionary experiences that frequently occur, but perhaps primarily, and crucially, because of the physical, moral, emotional, mental, and spiritual transformations that they perceive within themselves and within others as a result of drinking the Daime.

The Daime is understood to be much more than a drink that opens up the spiritual world. It is also seen as an all purpose healing elixir. Most people report feeling physically and psychically recharged after drinking the Daime, and the purging of parasites and toxins is an integral part of the healing process that it catalyzes. Similarly, contrary to the fear that the Daime is itself an addictive substance, there are countless accounts of the Daime's ability to overcome an individual's addiction to drugs and alcoholism. In *Morality as Practice*, the doctoral dissertation of Titti Kristina Schmidt, a Swedish anthropologist who spent fifteen months in Céu do Mapiá, there is an account of a man named Ernesto who was a drug addict before becoming a Santo Daime practitioner. In *Morality as Practice*, Ernesto describes the following difficult transition that he went through as he combated his drug addiction with the help of the Daime: "When I drank the Daime for the first time it was like hell. I went through a very tough period and didn't have any good experiences at all. The only thing I got was high fever, boils and wounds all over my body."[29] According to Ernesto, his limpeza, or cleaning, took several months. As he points out:

> I was so intoxicated by the drugs so the Daime had to work hard... . Eventually I started to feel better. I thought that I had recovered. So I stopped drinking the Daime and went back to drugs again. But this time it was really hell! Other drugs, which had earlier been a relief to me, did not work any more. After a couple [of] weeks I felt myself more or less forced back to the Daime. Then I started the whole procedure of 'cleansing' all over again. After some time my health improved and in due course I understood the power and the beauty of the Daime. Since then I have never touched any drugs.[30]

Practitioners of the Santo Daime tradition believe that the Daime can heal a wide range of severe illnesses. As Schmidt points out: "Céu do Mapiá has today a national reputation as a healing community. The villagers claim that they can treat a whole range of well-known diseases, for example, skin problems, respiratory diseases, contagious infections, hepatitis, diabetes, leprosy, malaria, worms, dysentery, digestive problems, anaemia, fevers, influenza, mental disorders" and so on.[31] According to Schmidt, "the community has also gained recognition outside Brazil, attracting people who hope to be cured from terminal diseases such as cancer and HIV/AIDS."[32]

People who come to the Santo Daime hoping to be cured of their illnesses often tell dramatic stories of their healing encounter with the Daime. Schmidt shares one such story in her account of Barbara, a woman diagnosed with an inoperable brain tumor:

> When Barbara started to drink the Daime she had what many members call a 'spiritual surgery' ... Under the influence of the Daime brew, she witnessed her own operation done by a group of doctors in spiritual form. After the operation, the spirits told her to rest and eat only certain prescribed food. Later when Barbara recovered, she returned to the hospital in Sao Paulo and asked them to [t]ake a new x-ray. To the surprise of the doctors, the tumor was gone. What amazed them even more was that Barbara (who has no Western medical training) could explain the whole operation, which corresponded to an ordinary brain surgery. She could even describe the instruments used by the spiritual doctors, instruments that, according to Barbara, the doctors in Sao Paulo confirmed were similar to the ones used during ordinary brain surgeries.[33]

Dramatic physical cures are not the only transformative effects that can be attributed to the Santo Daime. There are also numerous positive social and ecological changes that have been catalyzed by practitioners of the Santo Daime movement. For instance, Céu do Mapiá is regularly visited by many Brazilian authorities who see it as a model community to be emulated by other villages in the Amazon rainforest. Individuals within Céu do Mapiá have consciously attempted to create an eco-village where there is a strong focus not only on protecting the ecosystem in the two National Forests that surround Céu do Mapiá (National Forests that were created in large part due to the concerted initiative of leading members of the Santo Daime movement in the late 1980's), but also on learning how to be self-sufficient by developing sustainable, ecologically aware interactions with forest resources. Schmidt points out that in 2002, "there were more than 40 ongoing projects within the village, aiming at, among other things, forest preservation, environmental education, and the production of alternative forest medicine and food."[34] Céu do Mapiá has also become a place for those living in the region to go for medical help and/or to find work. The village offers free medical care to the local population, and runs two hospitals: one that offers Western oriented medicine, and another that is based on alternative healing modalities.

Once again, even within the limitations of this extremely cursory investigation of the transformative effects of Santo Daime religious tradition, it seems valid to say that James's third criteria, "moral helpfulness," can be rapidly crossed off of our list as well. There is abundant evidence that the Santo Daime not only has the capacity to promote physical and psychological well being, but also fosters harmonious social interactions and promotes a love and respect for the natural world that is manifest in numerous concrete and ongoing environmental initiatives.

Taking all of this information into consideration, I would like to suggest that, based on James's three criteria for assessing the value and validity of mystico-religious experiences, we can, and perhaps should, conclude that this entheogenic mystical tradition is at least as worthy of our respect as any of the other more well known mystical traditions. Perhaps these entheogenic substances truly are what they are said to be: profound, sacred, God-given gifts that can powerfully assist us in our quest to know the true nature of ourselves, as well as the all-too-often hidden beauty of the world around us.

18. Written communication, 2008. Many Santo Daime practitioners claim that it is possible at times to have a joint "revelation" or visionary spiritual experience during a Daime work. Schmidt shares one of her own experiences that she believes possibly illustrates this phenomenon: "During a ritual when I was lying in the healing room feeling awful after having drunk the Daime I was overwhelmed by questions about the Daime and the spiritual world. Suddenly I spotted an old ... medium standing in the doorway. She looked straight at me. I looked back and, being under the effect of Daime, I started to question her and she answered all my questions patiently, none of us uttering a single word." Schmidt wondered about this incident for several days, not sure if the answers that she received from the woman (which she remembered clearly afterwards) were only part of her imagination. A week later she went to the old woman's house for a birthday party. She wasn't sure whether to ask the medium about the experience, so she just sat in the woman's kitchen, watching her wash dishes. Schmidt adds: "After a while I decided to ask her the same questions as I remembered them fairly well. Suddenly she stopped working, looked at me and said: 'Kristina why are you asking all these questions again. I have already answered them. Do you remember when I stood there in the doorway, looking at you, during the ritual?' 'Yes,' I said. 'Well, then you know already,' she said and continued with what she was doing." > "Undoubtedly one of the major reasons that anthropologists for so long underestimated the importance of hallucinogenic substances in shamanism and religious experience was that very few had partaken themselves of the native psychotropic materials (other than peyote) or had undergone the resulting subjective experiences so critical, perhaps paradoxically, to an empirical understanding of their meaning to the peoples they studied."
> -Michael J. Harner

Introduction

Humans have long understood that the ingestion of psychoactive chemicals via local flora and fauna produces powerful alterations in consciousness. However, this has been interpreted in a variety of ways depending upon the cultural context in which these substances are used. For example, the fungal parasite *ergot*, containing lysergic acid amide, occasionally appears on the rye crops of Europe, but "the purposeful hallucinogenic use of the fungus seems to have been restricted to ancient Greece" (Schultes & Hofmann 1979: 102).

In most ethnopharmacological studies, these substances are termed *hallucinogens* or *psychedelics*, in an attempt to classify the type of psychological experience that is produced. However, the term *entheogen*, meaning "plants or chemical substances which awaken or generate mystical experiences," (Forte 1997: 1) will be used in the present paper as an alternative to the more popular terms because the term one uses to label these substances is informative. The more popular terms, which emphasize primarily the sensory effects that are produced, fail to convey the great meaning and sacredness ascribed to these substances by ancient cultures. *Hallucinogen* implies that the resultant experiences are nothing more than fanciful delusions that lack significance in the real world. *Psychedelic* is a loaded term closely affiliated with the "drug culture" of the 1960's and 1970's so its use in the description of ancient cultures is confounded with recent historical associations that have nothing to do with ancient Pre-Columbian religion (for example, see Clark 1969).

It is not that previous treatments of Pre-Columbian religions have completely ignored the use and depiction of entheogenic substances in Mesoamerica (see Carrasco 1990). When discussions do mention entheogens in Mesoamerican religious practices, it is usually only brief lip-service paid to a topic that our modern prohibitionist values would rather not discuss (Martin and Grube 2000: 15). Notable exceptions to this rule are the work of Peter T. Furst (1972; 1974) and Haviland and Haviland (1995). I intend to pick up where Marlene Dobkin de Rios left off in her unheeded call from a 1974 issue of *Current Anthropology* for Mesoamerican specialists to "shed further light on the role of psychotropic flora and fauna in Maya religion" (Dobkin de Rios 1974: 152).

Dobkin de Rios was an anthropologist but not a regional specialist in the cultures of Mesoamerica so she appealed for assistance from Mesoamericanists, receiving many replies about her theories regarding entheogen use. However, most of the replies were very unwelcoming to her suggestions that ancient Mesoamericans used drugs and many esteemed scholars vehemently denounced her claims. Decades have passed with only negligible research conducted on the subject of entheogens in this region (with the exception of a chapter comprised entirely of secondary sources in Rudgley 1993) and scholars of ancient Mesoamerican religion appear to have utterly disregarded Dobkin de Rios. This paper will seek to end this trend by taking a close look at entheogens, their use in religious ritual and the depiction of their use in iconographic remains. In addition, an assessment of the ethnocentricism that hides the evidence of past entheogen use will ensue, referring to an *entheophobic* bias that permeates the methodologies of modern research priorities. The following discussion will attempt to revitalize entheogen studies as they pertain to ancient Mesoamerican religion and worldview.

Ancient Mesoamerican Religion

All the religions of the Pre-Columbian Americas share characteristics that distinguish them from the rest of the world. Their common metaphysical philosophy revolves around a belief in the interconnectedness of the natural, social and spiritual worlds where ancestors and deities are directly accessible through the proper ritual (Stover 1986: 516-517). However, within North and South America, indigenous cultures differ drastically when compared to each other and the two continents' native groups are separated into many diverse cultural regions of which Mesoamerica is one of the most archaeologically rich.

The religious traditions of the Mesoamerican region are diverse relative to each other but are grouped together because they exhibit many mutual qualities that have diffused throughout the region from Northern Mexico to El Salvador after thousands of years of war and trade (Joyce 2004). Native American understanding of the cosmos revolved around a belief in three separate levels of the universe: a divine realm in the sky, a gruesome underworld and the human middle realm. They recorded their religious performances, aimed at pleasing the pantheon of deities above and below them, on public works of text and iconography depicting "burning of incense, dances, games, and other dramatic performances, and also human sacrifice, often paired with militaristic symbolism" (Joyce 2004: 7). Not surprisingly, the most important aspects of Mesoamerican life were also the foremost spiritual concerns, such as the connection of maize (corn), the main part of their diet, with the rain god (Dobkin de Rios 1974: 151). This common religious ideology of the region was organized around a unique conception of cyclical time where a sophisticated knowledge of mathematics was employed to track the movements of the stars relative to a precise calendar (Joyce 2004).

So it is established that the content of Mesoamerican religious texts and monumental iconography were exclusively reserved for the most significant aspects of their culture. So why is there so much artistic and textual reference to the use of entheogens? The obvious answer would be that these sacred substances were very important to ancient Mesoamerican religious rights and that their use was perceived to be a holy act. However, the archaeological and ethnohistorical literature has essentially ignored the influence of these substances and the few references that do occur are made in passing as if the author acknowledges their modern status as objectionable. A good example of how customary Western values have corrupted our view of ancient religion is found in a recent National Geographic article entitled "Descent into the Maya Underworld." In this article, which claims to be a portrayal of modern and ancient Mayan religious beliefs, there is only one mention of a shaman drinking "*balché*, a mildly intoxicating beverage, almost non-stop" (Roberts 2004: 43). Balché is a fermented alcohol derived from the bark of a local tree that has not been criminalized (Konzevik Cabib 1998: 663), unlike the many entheogens. Noticeably absent are the notorious *xibalbaj okox*, "underworld mushroom," also known as the *k'aizalah okox*, "lost-judgement mushroom," mentioned in ethnohistoric accounts (Sharer 1994: 542).

As the following discussion will demonstrate, the omission of entheogens in the study of Mesoamerican religions is a serious oversight. It is difficult to deduce whether the above religious traits were inspired by the use of entheogens or whether predetermined worldviews embodied an ideological environment into which entheogens were naturally integrated. The chicken-or-egg origins squabble is irrelevant to the present discussion which will focus on filling in the gaps of past accounts of ancient Mesoamerican religion that were incomplete because of their disregard for the obvious ritual importance of entheogens.

Archaeological Evidence for Entheogens in relation to their Psychoactive Properties

This section will seek to build on the efforts of Dobkin de Rios (1974) to whom much credit is warranted even though she concedes that her treatment of the topic was woefully inadequate. At the end of her article, "The Influence of Psychotropic Flora and Fauna on Maya Religion," appears a series of responses from various scholars. As expected, there are those for and against her opinion, but perhaps the most significant responses are those from two of the most prodigious luminaries in the history of Maya archaeology; Tatiana Proskouriakoff and J. Eric S. Thompson. Proskouriakoff states that:

> "Direct flights of fancy such as [Dobkin de Rios] offers here should have no place in a scholarly journal, and I think that the referees have been guilty of a serious error of judgement." (Proskouriakoff's reply in Dobkin de Rios 1974: 159)

Although J. Eric S. Thompson had previously acknowledged that the Maya probably utilized entheogens in a religious context (Thompson 1970: 185) he is pessimistic:

> "It is surely rash to substitute for such strong mythological associations the theory that we are faced with representational evidence that the Maya used toad and water lily in hallucinatory rites. Apparently, the properties of the two have become known to science only in recent years; that they were known to the Maya finds no support from any observations by outsiders from the conquest to the present or from Maya colonial writings." (Thompson's reply in Dobkin de Rios 1974: 160)

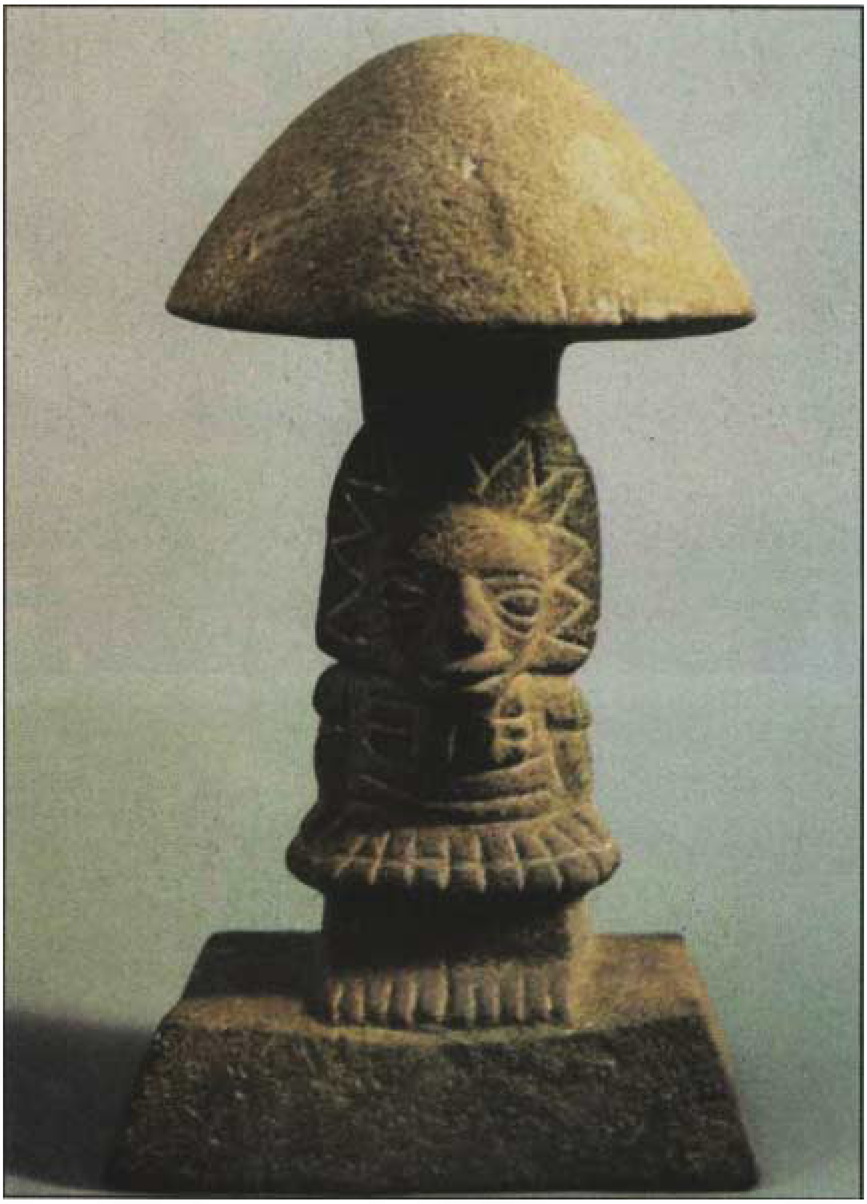
However, as Dobkin de Rios points out, statistical surveys have shown that researchers tend to overlook the importance of entheogens within a culture until they experiment with the chemical themselves (Dobkin de Rios 1974: 161).

Proskouriakoff and Thompson's pessimist attitudes, as shown above, act as a stumbling block for impartial research that is attempting to further the discipline in the face of "the conservatism of Maya scholarship" (Dobkin de Rios 1974: 162). Unfortunately, since Dobkin de Rios' pleas for scholarly rigour went unheeded, we must proceed according to the fact that a knowledge and understanding of the effects of these substances has yet to be effectively linked with the already substantial corpus on Mesoamerican religion. It is hoped that the mind-altering substances explained below will be incorporated into contemporary models of Mesoamerican religion to produce a much more inclusive and complete understanding of Pre-Columbian spiritual beliefs.

Dobkin de Rios refers to the work of Arnold Ludwig (1969: 13-16) who devised ten general distinguishing characteristics of altered states of consciousness that can be applied to entheogen-induced religious experiences: (1) altered thinking/concentration, (2) modified sense of time, (3) loss of control (depending on cultural worldview this can be a positive or negative encounter), (4) eccentric emotional expression making intoxication obvious, (5) altered sense of one's own body and atypical sense of self, (6) sensory distortions including synaesthesia, (7) unconventional meaning/significance given to one's surroundings and events compared to sober state, (8) belief in the acquiring of ineffable knowledge, (9) mental and physical sensations of invigoration and, (10) hypersuggestibility and the loss of conceptual and behavioural inhibitions. Ludwig's description stands in stark contrast to the "objective" portrayals of the mushroom experience found in pharmacological volumes where they are said to cause "*disturbances* in thinking, *illusions*...and *impaired* ego functioning" (Julien 2005: 612 emphasis added).

Mushrooms

Several genera of mushrooms contain the entheogenic chemical, psilocybin (4-phosphoryl-DMT) or psilocin (4-hydroxy-DMT), including *Psilocybe*, Stropharia, *Panaeolus*, *Copelandia*, and *Conocybe*. It does not matter which of the two chemicals the mushroom contains because psilocybin is transformed into psilocin during digestion (Julien 2005: 610).



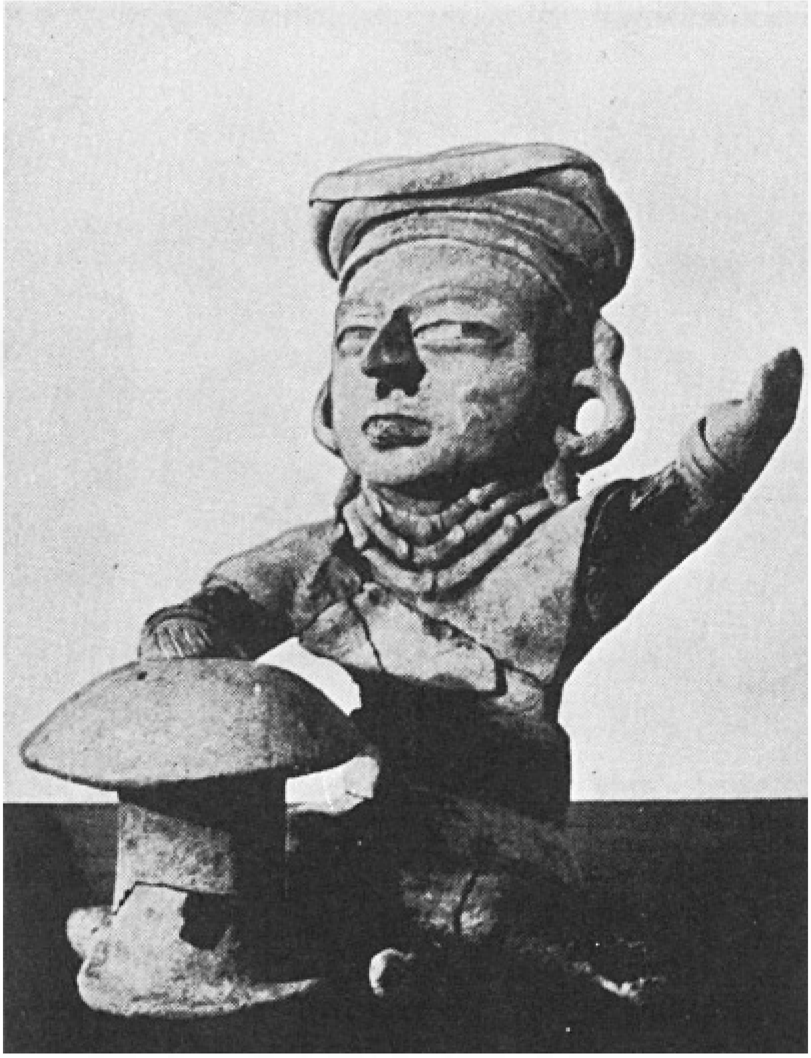
Mushroom stone with human effigy, from Wasson 1980: 176.

Mushrooms are arguably the most frequently depicted entheogen in the archaeological record of Mesoamerica and probably the most widely utilized because they are one of the only substances that requires no preparation to achieve the desired effects. Chemists and psychologists have said the effects of psilocybin are comparable to those of LSD but they have also been equated to psychosis. The Pre-Columbian use of entheogenic mushrooms was seen in a totally different sense where the effects were attributed to contact with divinities and fantastic mental journeys. Known to the Aztecs as *teonanacatl* ("flesh of the gods"), psilocybe mushrooms were promptly demonized by Christian missionaries soon after European contact in the 17th century. The religious persecution of the use of these mushrooms resulted in their use being hidden from foreigners until knowledge of them was rediscovered in the 1950's by R. Gordon Wasson, a banker from New York City (Beyerstein & Kalchik 2003: 17; Julien 2005: 612). Wasson ventured deep into the Oaxacan highlands of

Mexico in search of the fabled mushroom shaman, María Sabina. He was the first foreigner to participate in the sacred *Velada* ceremony, which he described in numerous writings upon his return to the United States:

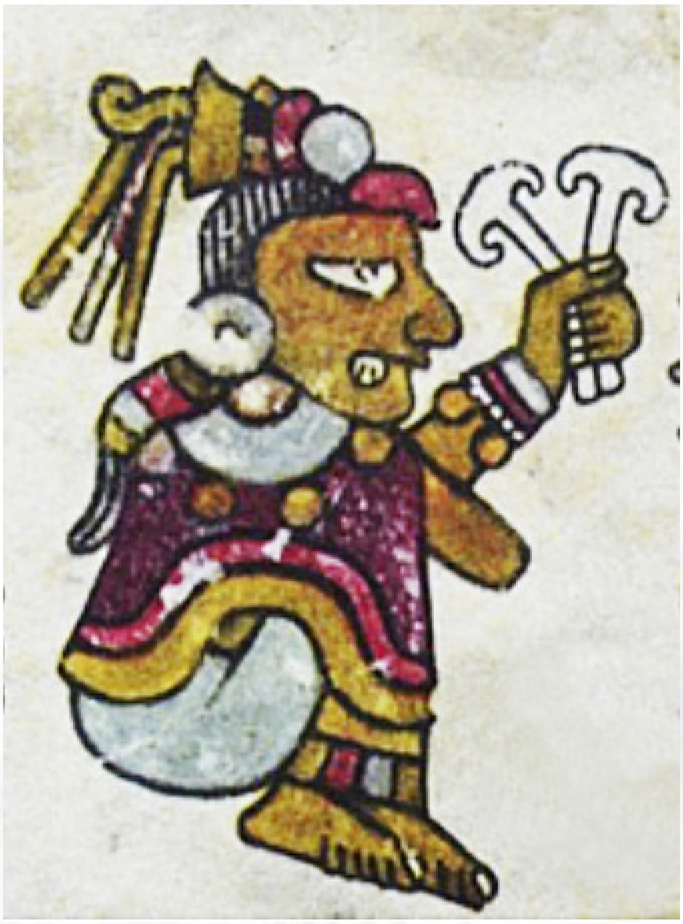
> "the mushrooms gave me no choice. They took full and sweeping possession of me. There is no better way to describe the sensation than to say that it was as though my very soul had been scooped out of my body and translated to a point floating in space...we saw geometric patterns, angular not circular, in richest colors...the patterns grew into architectural structures, with colonnades and architraves, patios of regal splendor, the stone-work all in brilliant colors, gold and onyx and ebony, all most harmoniously and ingeniously contrived, in richest magnificence extending beyond the reach of sight." (Wasson 1980: 15)

Wasson's qualitative description of the experience is essential because it adds an empathetic quality that more detached scientific descriptions lack. The purpose of focussing on these empirical descriptions is to open a previously closed window of understanding when paired with the ancient Mesoamerican cultural context. The importance of the sciences in aiding the research of social scientists is not devalued in this approach. Nevertheless, for studies regarding religious transcendence I believe it to be much more vital to appreciate the full scope of the altering of consciousness instead of relegating these mental journeys to materialistic quantifications.



Priestess and mushroom stone, from de Borhegyi 1963: 332.

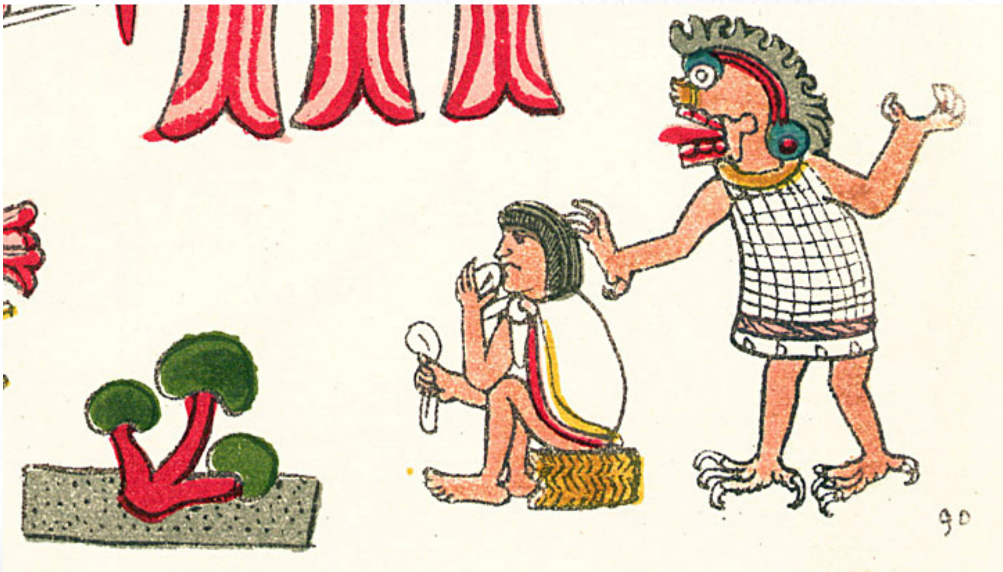
Archaeological evidence for the use of these mushrooms is found in the iconographic representations of mushrooms being ingested and the numerous mushroom shaped *altars* that are found throughout Mesoamerica. An ethnocentric bias on the part of the scholars studying ancient Mesoamerican religion attests for the oversight regarding the connection between these altars and the ritual use of entheogenic mushrooms. Mushroom altars were made of both stone and ceramic, often accompanied with ideologically significant effigies build into the base (de Borhegyi 1963; Kohler 1976). One Pre-Columbian pottery figurine from Veracruz, Mexico represents a woman whose "left hand rests on a plain, hollow pottery mushroom, while her right arm is extended upward as if in prayer" (de Borhegyi 1963: 332). It appears as if this figure is a depiction of the ceremonies in which the mushroom altars were employed for spiritual purposes, possibly as effigy altars of the sacred "flesh of the gods" that were simultaneously consumed.



Vindobonensis codex, from Schultes & Hofmann 1979: 146

There are also scriptural references to the use of entheogenic mushrooms. In the *Vindobonensis* codex, "nine deities receive instructions from Quetzalcoatl on the origin and use" (Schultes & Hofmann 1979: 146) of the mushrooms. The depiction of deities alongside someone consuming mushrooms in the Aztec *Magliabechiano* codex serves to further the notion that these mushrooms were eaten in a ritual context (Wasson 1980: 113). When one considers the portrayals of mushrooms in scriptural codices and the mushroom effigy altars, it becomes difficult to argue against the idea that mushroom ceremonies were being performed in ancient times much like they were when Wasson participated in the Oaxacan Velada in 1955.

There are over 20 different species of entheogenic mushrooms found in Mexico so it is reasonable to make the connection between the known transcendental properties of psilocybin mushrooms and the use of mushroom altars in ritual consumption ceremonies (Dobkin de Rios 1974: 148). If one looks at Wasson's description of the experience, it becomes clear that if indeed these mushrooms were being used in religious ceremonies, the cultural impact would be considerable. This is especially true in the case of Amerindian traditions. In the context of their holistic worldview, these experiences would not be considered illusions; rather, the visions caused by these mushrooms would be interpreted as genuine voyages to otherworldly realms.



Magliabechiano codex, from Wasson 1980: 113

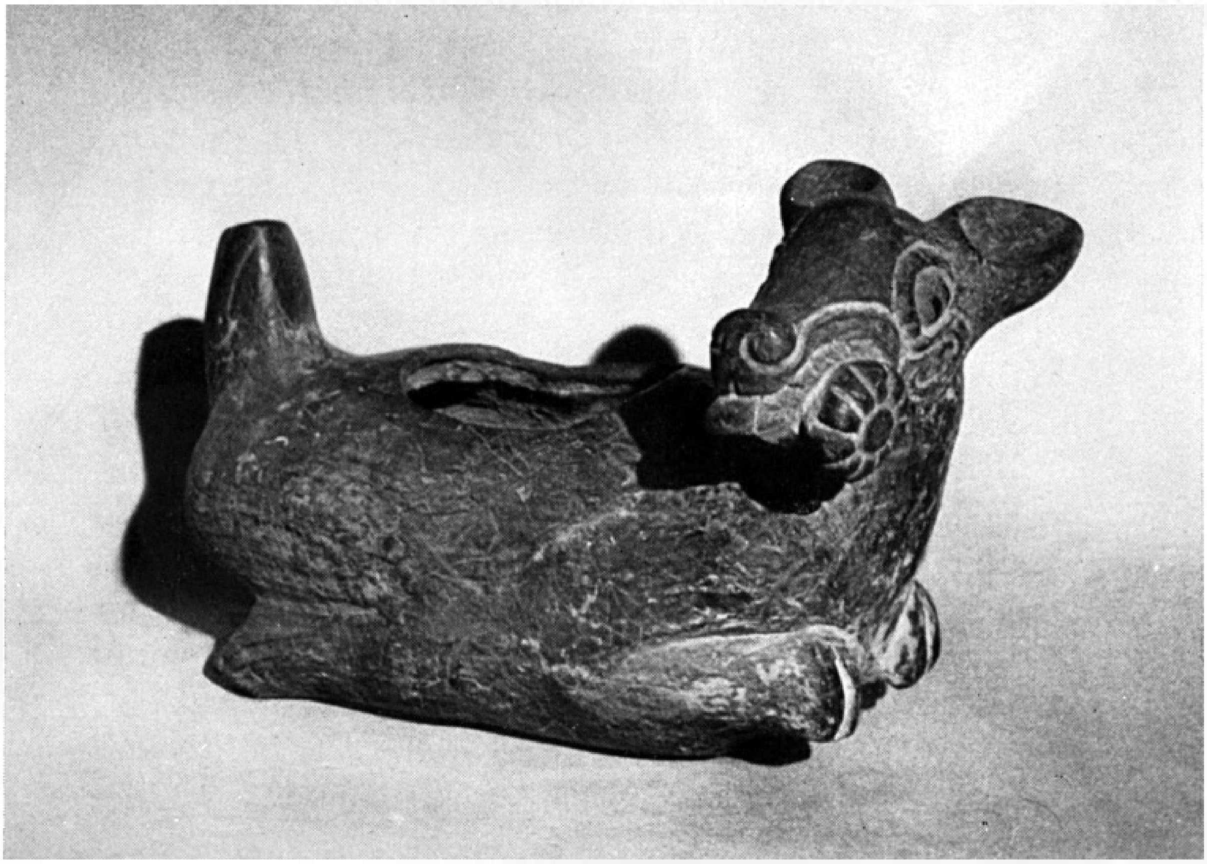
Peyote Cactus

Lophophora williamsii, or peyote, is a common cactus species found in western Mexico and the South-western United States, which contains the entheogenic chemical mescaline in the "button," a small blossom at the end of the cactus branches (Julien 2005: 594). Evidence for Pre-Columbian use of peyote is scantier than that of other entheogens, and it was most broadly documented in the years following European contact (Furst 1972: 136-137). One exception is an archaeological investigation conducted at a three thousand year old cave site in Texas that yielded peyote buttons "found in a context suggesting ceremonial use" (Schultes & Hofmann 1979: 132). The entheogenic properties of mescaline are comparable to LSD and psilocybin in that they produce dazzling visual effects that are best described by the great novelist/poet Aldous Huxley, who wrote a book about his experiences with mescaline:

> "I continued to look at the flowers, and in their living light I seemed to detect the qualitative equivalent of breathing - but a breathing without returns to a starting point, with no recurrent ebbs but only a repeated flow from beauty to heightened beauty, from deeper to ever deeper meaning. Words like "grace" and "transfiguration" came to my mind, and this, of course, was what, among other things, they stood for. My eyes traveled from the rose to the carnation, and from that feathery incandescence to the smooth scrolls of sentient amethyst which were the iris. The Beatific Vision, Sat Chit Ananda, Being-Awareness-Bliss - for the first time I understood, not on the verbal level, not by inchoate hints or at a distance, but precisely and completely what those prodigious syllables referred to." (Huxley 1954: 18)

It is curious that a plant that produces such an awe-inspiring experience would fail to gain the iconographic prominence of the other entheogens. However, this may have to do with the conflating of peyote's identity with other psychoactive plants of the region.

J.S. Slotkin (1955) conducted a survey of the missionaries' written records and found that the interchangeable terms *peyote* and *peyotl* were generally used by colonizers to refer to the myriad of strange substances consumed by the natives. He points out a glaring problem in the ethnobotanical literature where scholars have assumed the straightforwardness of historical references to peyote, even when there is no solid evidence that the use of this term, and the many other native terms, refers directly to the mescaline cactus (Slotkin 1955). This obscurity may be attributed to the fact that native groups did not categorize peyote buttons separately, or perhaps the motif of peyote in Mesoamerican art is still unknown to iconographers. One exception is a "snuffing" effigy pipe dating to 500 B.C. from the Oaxacan site of Monte Albán "in the form of a deer with a Peyote in its mouth" (Schultes & Hofmann 1979: 133). There is also the suggestion that the bright, vibrant colours preferred by many Mesoamerican cultures for use in decorations and blanket/clothing patterns were inspired by the visions induced by peyote (Beyerstein & Kalchik 2003: 21).



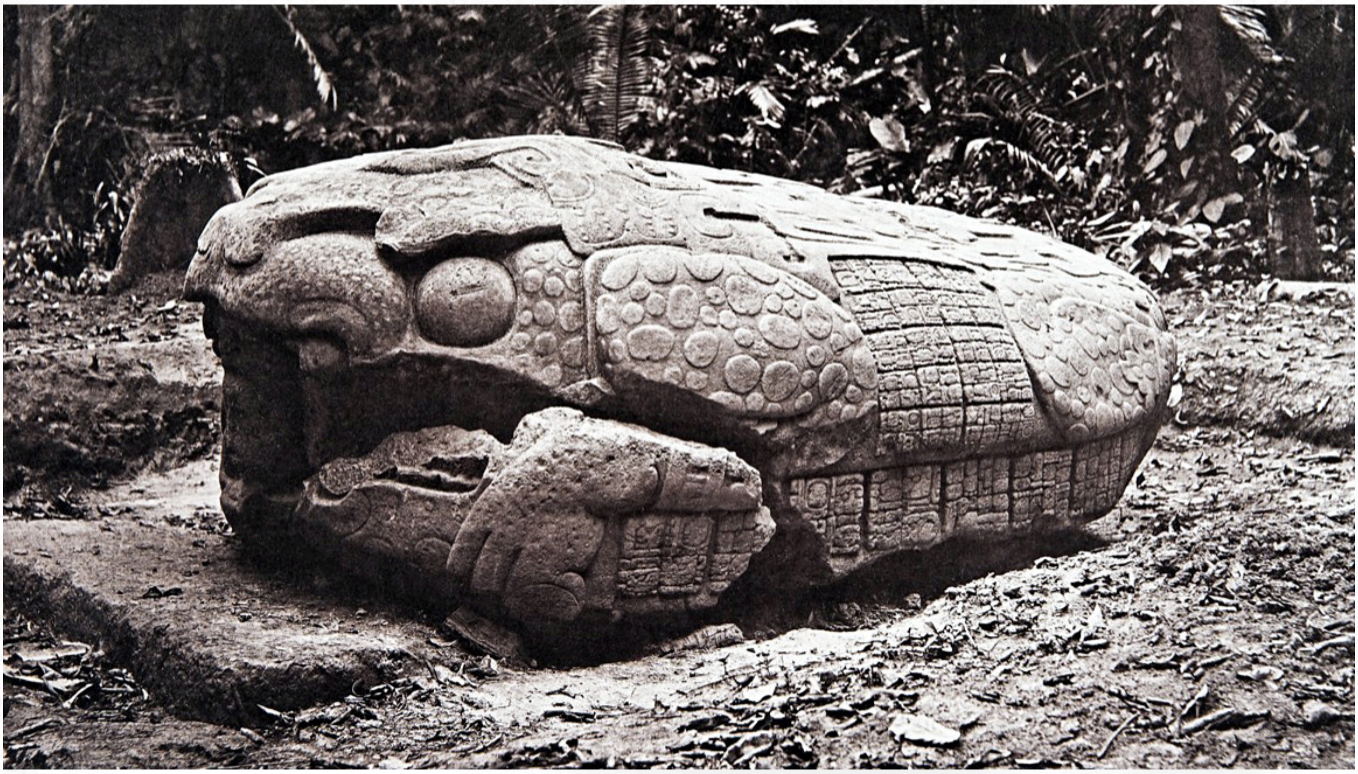
"a deer with a Peyote in its Mouth" (Schultes & Hofmann 1979: 133)

It is clear that there was widespread use of peyote buttons at the time of European contact and these practices were aggressively condemned by Christian missionary powers. In fact, peyote represented perhaps the most severe offence to Christian authorities because native groups who were being converted began to associate the divine properties of peyote with images of the infant Jesus (Wasson 1980: 144). This infuriated missionaries who were trying to convert the natives and convince them of the Christian path to God. Instead, they found the natives resorting to traditional paths to the divine via the ingestion of entheogenic flora and fauna.

Toads

The possible use of toad toxins for entheogenic purposes has long been debated and continues to be an uncertain theory. What is certain is that the toad was recurrently depicted in Mesoamerican art (see Kennedy 1982), possibly more than the mushroom and at times with the toad image forming the base of mushroom stones (see Wasson 1980: 184-185). Many species of the toad genus *Bufo* have paratoid glands that excrete the entheogenic chemical 5-hydroxy-DMT, also called bufotenine. Bufotenine, which resembles psilocin in structure, is only entheogenically active when administered by smoking or snorting and when combined with some type of MAO (monoamine oxidase) inhibitor (Beyerstein & Kalchik 2003: 26). As you will see below with the discussion of Ayahuasca, MAO inhibitors are needed for certain chemicals to protect the entheogenic molecule from being broken down before its effects are felt.

Much of the literature concerning the use of toad venom as an entheogen has died out since the 1992 publication of an antagonistic paper by ethnobotanists Wade Davis and Andrew Weil. In their article, they point out the many discrepancies that have confounded past attempts to link the abundant iconographic representations of *Bufo marinus* toads to their use as entheogens. Naturally, Davis and Weil attack the lack of ethnohistorical evidence, but I would reply that perhaps after the zealous missionaries targeted their other entheogens, such as mushrooms and peyote, the Mesoamericans tried to protect their remaining entheogens by not allowing the colonizers to know about their existence. Davis and Weil also point out the fact that *Bufo marinus* toxin, besides containing bufotenine, also contains bufogenin and bufotoxin, which are both powerful poisons that were used in Europe as murder weapons (Davis and Weil 1992: 51-52).



"Monolithic Animal G", from the site of Quirigua, in Kennedy 1982: 278.

I am not yet prepared to declare dead the possible connection between iconographic representations of the toad on pottery and stone, and its use as an entheogen. After all, there are copious depictions of *Bufo marinus* that distinguish it from other Mesoamerican toad species by its unique cranial crest, paratoid and tibial glands, and its middorsal vertebral stripe. The majority of representations of *Bufo marinus* are unmistakable because of the consistently identical representation of the paratoid glands (the source of the toxin) as liver-shaped disks above the shoulders with numerous punctated marks to signify the venom-secreting pores. Perhaps the best of all representations of these *Bufo marinus* characteristics is the unmistakable "Monolithic Animal G" from the Guatemalan site of Quirigua (Kennedy 1982: 277-278). With these unambiguous depictions of *Bufo marinus* appearing so frequently across Mesoamerica, is it possible that they figured out a way to circumvent the poison problem? Kennedy (1982) describes a possible method whereby the toxic toads could have been fed to ducks, which are known to have livers that are uniquely capable as detoxifiers and would then allow the hallucinogens to be exploited through the ingestion of the ducks' livers. Interestingly, ducks are a common theme in the art of the Olmec, a pre-Mayan people of the Gulf of Mexico coast. It is at the Olmec site of San Lorenzo where one of the biggest collections of *Bufo marinus* bone dumps was found in association with an unexplainable U-shaped "water control system." This structure has puzzled archaeologists and could only be described by researchers as pertaining to "ritual use." Kennedy cannot help but propose that perhaps this cistern, which is too small for human bathing, might have been used as a place for ducks to swim while they were fed *Bufo marinus* (Kennedy 1982: 286). These collections of toad bones have been found all over Central America but they present a dietary anomaly because of the presumed toxicity of the toads (Davis and Weil 1992: 53).

Davis and Weil (1992) are correct in their assessment of *Bufo marinus* toxin as being too poisonous to be ingested in an unmodified form and that bufotenine might not be entheogenic after all, but they do point to an interesting *Bufo* species found in the American mid-west called *Bufo alvarius*. This particular species also secretes bufotenine but it has entheogenic properties only because it also contains O-methyl transferase, which converts the small proportion of bufotenine into the very strong entheogen, 5-MeO-DMT, increasing this chemical's proportion in the toxin from zero to a whopping 15% (Davis and Weil 1992: 55). Therefore, it could be argued that ancient Mesoamericans could have combed their amazingly diverse forests (fourth most plant species among regions of the world[1]) for O-methyl transferase, which they could have found in trees of the genus *Pinus*[2]. Wade Davis describes his experience after smoking 5-MeO-DMT from *Bufo alvarius*:

> "Shortly after inhalation I experienced warm flushing sensations, a sense of wonder and well-being, strong auditory hallucinations, which included an insect-cicada sound that ran across my

> mind and seemed to link my body to the earth. Though I was indoors, there was a sense of the feel of the earth, the dry desert soil passing through my fingers, the stars at midday, the scent of cactus and sage, the feel of dry leaves through hands. Strong visual hallucinations in orblike brilliance, diamond patterns that undulated across my visual field. The experience was in every sense pleasant, with no disturbing physical symptoms, no nausea, perhaps a slight sense of increased heart rate." (Davis and Weil 1992: 56).

If we accept the ingenuity of the Mesoamerican peoples, it is possible that they were able to test different *Bufo-Pinus* concoctions on prisoners that had been acquired from war victories (Sharer 1994: 144), much like the Nazi medical experiments, until a safe and effective mixture of 5-MeO-DMT was developed from *Bufo marinus* toxin.

Ayahuasca

Ayahuasca is a tea beverage that is still popular among Amazonian native groups and was the subject of the most comprehensive phenomenological survey ever conducted on an entheogen. Benny Shanon, an Israeli cognitive psychologist, published *The Antipodes of the Mind: Charting the Phenomenology of the Ayahuasca Experience* (2002), which now stands as the standard review of the experiences induced by an entheogen. Shanon is a reputable cognitive psychologist whose writings on the Ayahuasca experience present a fair and unbiased account of substances that are currently banned and considered scandalous in modern Western societies. In comparison, Wasson's work on mushrooms is helpful, but he was not a professionally trained scholar, let alone his lack of training in the culture of Mesoamerica. Benny Shanon, on the other hand, has provided an invaluable academic text, which would be idyllic to have for every entheogen discussed here. Like a cartographer who maps a geographical region of the earth, Shanon describes every facet of the Ayahuasca intoxication in intricate detail, combining the contents of visions with corresponding philosophical and psychological concepts.

The active entheogenic chemicals in Ayahuasca are DMT (N, N-dimethyltryptamine), usually derived from the *Psychotria viridis* bush and MAO inhibitors, such as harmaline/harmine that normally come from the *Banisteriopsis caapi* vine, which act as entheogens and prolong the experience by slowing the breakdown of DMT (Shanon 2002: 15-16). DMT is the main entheogenic constituent to the tea and even when administered by itself, it is one of the most potent and fast-acting entheogenic chemicals. It has been synthesized and made into snortable or smokeable crystals in modern times, but for the most part, DMT was administered to people in ancient times as a tea, such as Ayahuasca (Julien 2005: 609). An initial problem is that there is no evidence for the use of Ayahuasca in the archaeological record, but this does not rule out its use because as one can see from the above discussion of obvious entheogen use, the ancient entheogenic rituals are only evident when the researcher is willing to open their eyes to the evidence.

It can be safely argued that the seeking out of methods with which to gain transcendence was an important aspect of ancient Mesoamerican religion. We can see this in the insatiable trial-and-error with which they discovered the entheogenic properties of many plants and the possibility of their experimentation with the extraction of bufotenine. Even though neither *Psychotria viridis* nor *Banisteriopsis caapi* are found in Mesoamerica, there are plants native to Mesoamerica that contain DMT and MAO inhibitors. *Mucuna pruriens*, otherwise known as Cowhage, is a DMT-containing climbing plant native to many parts of the world, including Mexico and Guatemala.[3] Also, *Ceiba pentandra*, a religiously significant tree to the Maya (Sharer 1994: 33), contains the MAO inhibitors kaempferol and tannin,[4] neither of which is toxic.[5,6] Therefore, we can cautiously suggest that Mesoamerican cultures exploited the plants in their territory in the same manner as their Amazonian counterparts managed to perfect their Ayahuasca beverage after millennia of trial-and-error "research."

Out of the millions of species of plants in the rainforest, to find one of the ingredients to Ayahuasca is amazing, but to find the correct pairing is an astounding feat (Shanon 2002: 16). Shanon sums up his competent familiarity with Ayahuasca by stating:

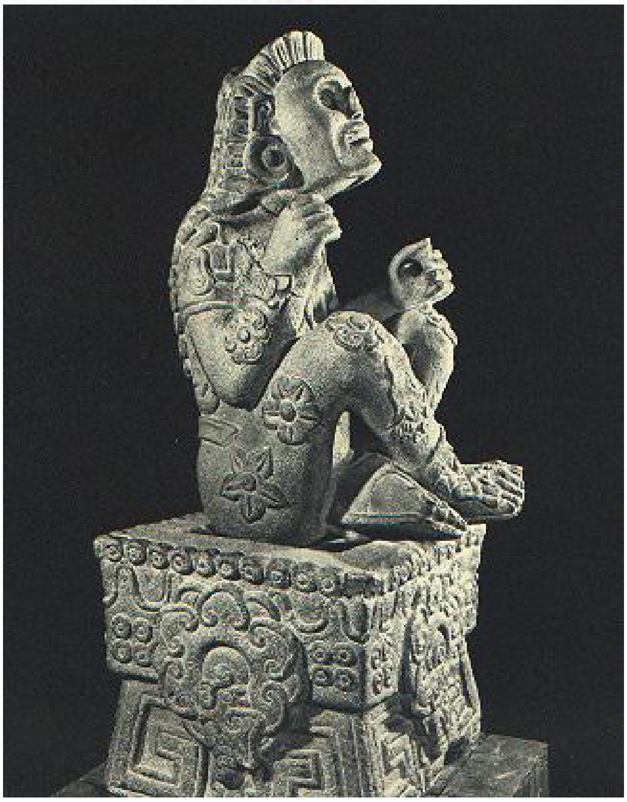
> "Personally, if I were to pick one single effect of Ayahuasca that had the most important impact on my life...I would say that before my encounter with the brew I was an atheist...and when I

> returned back home after my long journey in South America, I no longer was one. Likewise, a significant number of informants I have interviewed indicated that the main lesson they received from Ayahuasca was religious or spiritual. 'Ayahuasca showed me that God exists,' 'I have come to appreciate the place of the sacred in human life,' 'I have encountered the Divine,' are all statements I have heard more than one person say. There are many individuals who, in direct consequence of their experience with Ayahuasca, underwent a radical religious or spiritual conversion." (Shanon 2002: 260)

Such profound consequences of the Ayahuasca experience demand attention from Mesoamerican scholars. They should be emulating the cultures they are interested in by developing a propensity to seek out transcendence through meticulous investigation of, and experimentation with Mesoamerican flora and fauna. Of course, it could be argued that modern researchers can never fully recreate the experience in the same way as it was perceived by ancient Mesoamericans. Yet this is true of every archaeological investigation; for example, if we restore the Mayan pyramids to their original splendour, the awe that they inspire in modern viewers is not the same as it was in 700 A.D. The purpose of archaeology is to theoretically recreate ancient ideologies so that we can gain a better understanding of how the world appeared to the ancients. Entheogens offer us the same degree of insight into the minds of ancients as material objects extracted from the ground or the monumental architecture that dots the Mesoamerican landscape.

The Morning Glory and other Entheogenic Flowers

There were multiple flower species known to ancient Mesoamericans that contain entheogenic chemicals. Most notable is the use of the seeds of the Morning Glory flower (*Turbina corymbosa*), called *ololiuhqui* by the Aztecs, which contains lysergic acid amide (the same chemical that is found in the ergot fungus discussed earlier). The LSA molecule is almost identical in structure to the much more potent lysergic acid diethylamide (LSD), which was the central inspiration for the drug culture of the 1960's and 70's (Beyerstein & Kalchik 2003: 19; Clark 1969). Even though LSA is not as potent as LSD, when hundreds of seeds were ground into a powder, they would be blended into a cacao beverage and sometimes psilocybin mushrooms were added to the mixture (Wasson 1980: 98). Indeed, even though the Morning Glory is found throughout Central America and the Caribbean, it appears that they were only purposely used as entheogens within Mexico (Schultes & Hofmann 1979: 159).

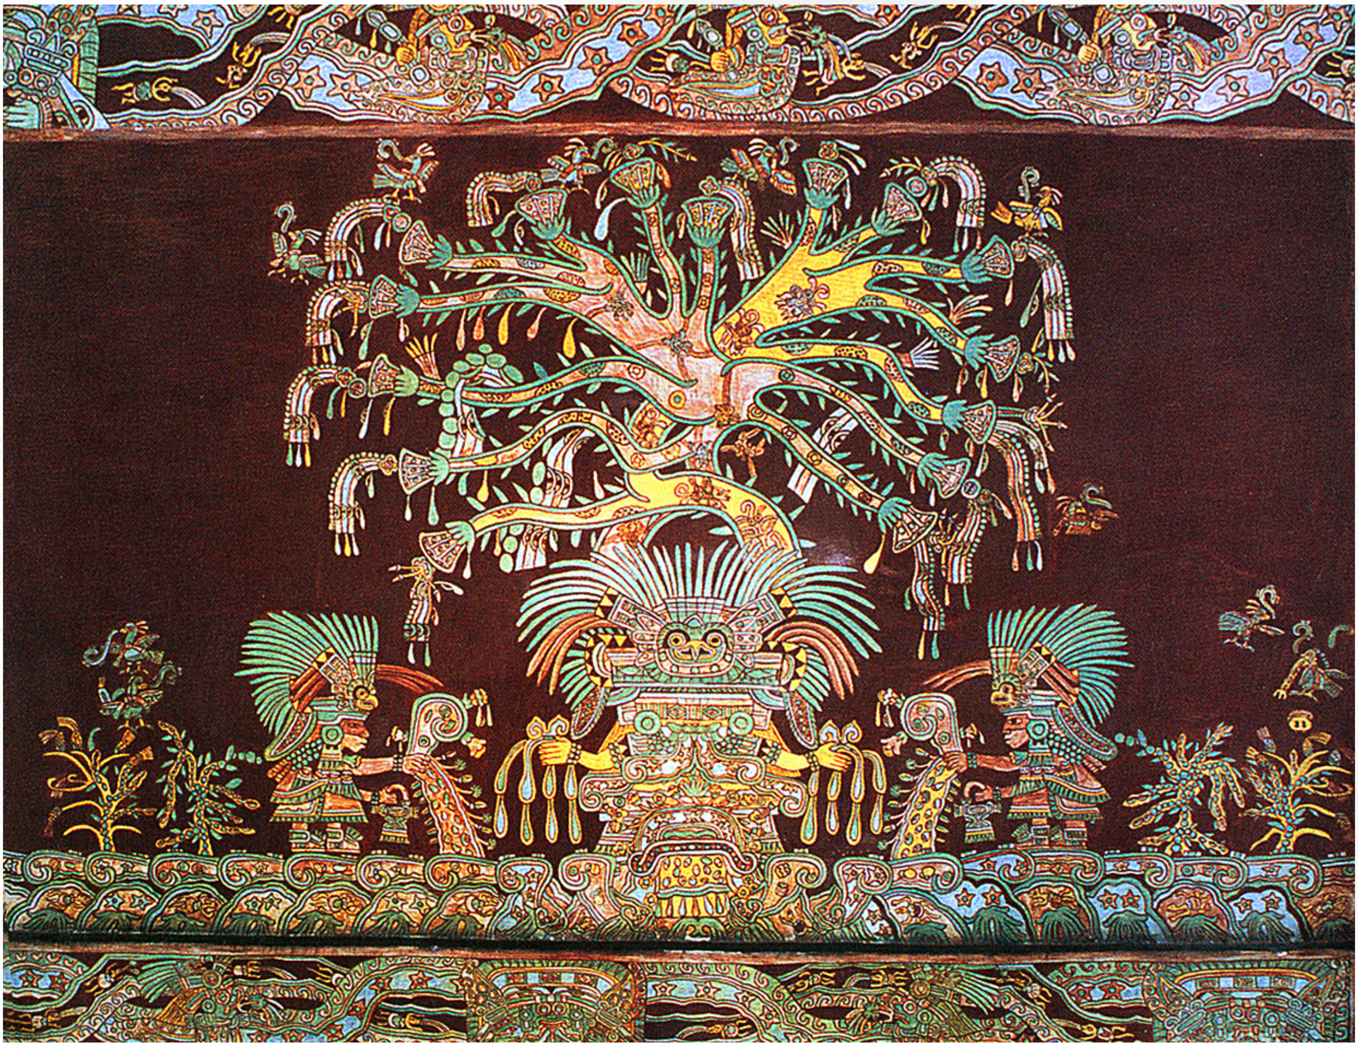


Xochipilli statue, in Wasson 1980: 61

Morning Glory seeds were an important device of the Aztec shaman, who used peyote while also drinking a concoction made of *ololiuhqui*, spiders, scorpions, salamanders and vipers. This beverage was called *Petun* and was esteemed by the Aztec shamans while the Spanish friars detested it because of the presumed devilish nature of the intoxication it produced (Dobkin de Rios 1984: 146). It is easy to appreciate the difficulty with understanding ideologies that are totally different than the modern Western worldview when one looks at translations of Aztec religious prayers to the ololiuhqui-specific deity:

> "Come now, come hither, Green Woman: behold the green heat (fever) and the brown heat: remove thou the flaming or scarlet heat, the yellow heat or by this token, I send thee to the seven caves. And I do command thee, put it not off till tomorrow or another day, for sooner or later thou wilt be compelled to do it. Who is the God - the so powerful and superior one - who can destroy the work of thy hands. It is I who command it, I the prince of enchantment." (cited in Dobkin de Rios 1984: 146)

Since this is a translation from the original Nahuatl into Spanish and now English, the obscurity of the prayer highlights the fact that certain concepts and symbolism only make sense in the context of the worldview in which they originate, and we are still a long way off from truly understanding the religious context in which this prayer would have made sense. It is also interesting that there is so much referral to colours and different types of heat. These colour and temperature references are understandable when one considers the content of the quotations in earlier discussions of entheogenic experiences.



Aztec Mother Goddess alongside *Ololiuhqui* vines with entheogenic "nectar" flowing out of the Morning Glory blossoms, in Schultes & Hofmann 1979: 160-161

There is a notable Aztec sculpture depicting their flower deity, Xochipilli, in a prayerful position with images of different flower species on his limbs and body. Besides the morning glory, there are illustrations of a tobacco leaf (*Nicotiana tabacum/rustica*[7]), mushroom caps, a sinicuichi flower (*Heimia salicifolia*[8]), a flower (poyomatli) from the cacahuaxochitl plant (*Quararibea funebris*[9]) and a still unidentified four-petaled flower. All of these flowers are known to have been categorized by the Aztec as aristocratic entheogens that were used mainly by the upper echelons of society (Wasson 1980: 64-71). Ololiuhqui was also praised by the Aztec's ancestors from the city of Teotihuacán who portrayed the experience of Morning Glory seeds artistically in a beautiful mural from 500 AD (Beyerstein & Kalchik 2003: 18-19). These are but a few of the many iconographic examples of entheogenic flowers but it is enough to suggest that Mesoamerican religion also held these types of entheogens to be of religious value. Like the other entheogens, *ololiuhqui* was also outlawed as an instrument of the devil (Furst 1974: 206).

From Proof to Practice: Lessons from Entheology

The iconographic and ethnohistorical evidence overwhelmingly illustrates that the ancient Mesoamericans revered the extraordinary properties of these entheogens enough to recreate them artistically. Therefore, it only makes sense that modern reconstructions of their religion should incorporate an appreciation for this reverence and an understanding of the states of consciousness that they induce in order not to overlook an important aspect of ancient Mesoamerican religious worldview.

The above discussion represents a rare conflation of the emerging field of entheology with the already established disciplines of art history and archaeology. It is hoped that further study will finally demand a response to Dobkin de Rios' 1974 plea for cultural scholars to familiarize themselves with entheogens. These substances and their influence on ancient Mesoamerican religion can no longer be ignored as they have been in the past. Future studies of Mesoamerican religion and worldview must now take into account the facts described above. Since it has been established that researchers tend to ignore entheogenic substances until they experience them themselves, it is advisable that scholars who intend to study the ideology of the peoples of Mesoamerica should pursue a comprehension of entheogenic experience in order to gain an appreciation for the cultural ramifications. Some may argue that there is still not enough evidence for the significance of these substances but if this is true, it is only because the iconographic remains have been assessed with an eye that is not looking for them. I will predict that when more researchers begin to acknowledge the metaphysical impact of entheogens and begin to look for representations of entheogenic flora and fauna that there will be an upsurge in the amount of iconographic evidence. It is also advisable that scholars begin to lessen their reliance on the ethnohistorical writings of the conquistadors and missionaries because these texts are prejudiced against the native uses of entheogens. The writings of the colonizers do not properly represent the sacredness imbued in these substances by indigenous Mesoamericans:

> "I believe that, incited by the cursed devil, these wretched Indians remain confused and are neither fish nor foul in matters of the faith." (Friar Durán, cited in Torrance 1994: 199)

Future studies of the religions of this region must begin to comprehend them from the point of view of the native, not that of those who oppressed and persecuted them. This requires a turn to iconography and a desire to understand how ancient Mesoamericans made sense of existence and the human condition. After all, that is the purpose of the pursuit of anthropology: to study the behaviours and customs of other cultures and compare them to ours in an attempt to better recognize what it really means to be human. Anthropology is hindered when the views of the modern West are projected onto the vastly different worldviews of non-western societies. The rest of this current study will strive to excavate the oversights of the past and suggest a more authentic reading of ancient Mesoamerican religion that includes an appreciation for the ritual use of entheogens.

Observing Entheophilic Ideologies from an Entheophobic Perspective

There are seemingly endless possibilities to the structure and scope of human ideologies. However, each ideological system is regarded by its followers as the one true explanation of reality while all competing versions are held to be irrational and false. When one really delves into the subject of basal metaphysics, it becomes clear that all of them are groundless descriptions of an existence that is intrinsically beyond human understanding. Earnest Becker declares that "this is what society is and always has been: a symbolic action system, a structure of statuses and roles, customs and rules of behaviour, designed to serve as a vehicle for earthly heroism" (Becker 1973: 4). By heroism, he is referring to the seeking out of a feeling of purpose and specialness within a metaphysical reality that is fundamentally devoid of knowable purpose. For Mesoamericans, "ritual coercion is one response to the uncertainties of a world never fully conformable to human need" combined with the "incorporation of more flexible means of transcendence through personal communication with the divine" (Torrance 1994: 197). In short, it is the curse of the human condition that no one can know what the true meaning of life is, so we fabricate a system that reinforces itself as the ultimate depiction of what reality *is*. I believe this process of demoting other cultural worldviews in defence of our own secretly arbitrary pursuit of heroism has resulted in an ethnocentrically skewed conception of ancient Mesoamerican religion. The above synopsis serves to demonstrate that past scholars have certainly overlooked the importance of entheogens in ancient Mesoamerican spirituality, but why did this omission occur across the discipline?

I propose that the oversight is related to a worldview classification scheme established by R. Gordon Wasson. Wasson was mainly focussed on the use of mushrooms in different societies and he noticed that the perception of mushrooms crossculturally was separated into those worldviews that liked mushrooms (*mycophiles*) and those that had a fear of them (*mycophobes*) (Wasson 1980: xv). I want to expand his classification for the purposes of this paper to a broader ideological breakdown of all cultures as either *entheophilic* or *entheophobic*. This new typology will serve to reassess the misguided outlook that has been assumed by modern scholars as they approach ancient religious ideologies. As seen in our legal codes, the modern Western worldview holds that all intoxication, other than that brought on by alcohol, is objectionable and immoral. Conversely, Pre-Columbian peoples were ignorant of the practice of alcohol distillation and could only produce a few fermented alcohols from cacti, maize, honey, or pineapple, all of which were strictly regulated:

> "Among the ancient Aztecs, getting drunk without incurring the wrath of society was a privilege of old age; drunkards could receive severe punishments, ranging from public disgrace to death by stoning or beating" (de Smet 1985: 20).

When one considers this outlawing of alcoholism with the overwhelming evidence for the use of entheogens by ancient Mesoamericans, it appears that their social rules regarding intoxication represent the antithesis to the laws of the modern West. It can be safely concluded that all studies of ancient Mesoamerican religion and worldview that have excluded entheogens exhibit entheophobic bias that precludes the importance of these substances for entheophilic ideologies. I will illustrate this point through a critique of Davíd Carrasco's Religions of Mesoamerica (1990).

Entheophobic Bias as the Continuation of the "Noble Savage" Falsehood

Davíd Carrasco is currently Rudenstine Professor of the Study of Latin America at the Harvard Divinity School, and one of the leading authorities on Mesoamerican religion[10]. In his overview of past and present Mesoamerican religion (Carrasco 1990), there is only one reference to the use of entheogens in Mesoamerican religious practices; a remiss narrative on the use of peyote by the Huichol groups of Western Mexico as "one outstanding example" (Carrasco 1990: 138).

Considering the mass of evidence described above, it is not justifiable to exclude the ritual use of entheogens in an overview of Mesoamerican religion. Nevertheless, Carrasco (1990) deems it necessary to dedicate an entire chapter to the Christianization of Mesoamerican society and devotes only three pages to discussing the sanctity of vegetation. Under the heading "Plants and the Sacred Dead," the author describes the religious significance of agricultural crops without a single mention of the employing of entheogenic plants in religious rights (Carrasco 1990: 27). This massive oversight is doubtlessly the result of a hidden ethnocentric bias rooted in the training of today's scholars of religion and culture. Regrettably, it is virtually impossible to separate oneself from one's acculturation into the modern worldview, let alone an instinctive reverence for the assumedly objective truths of one's own moral standards.

The moral structure of today's modern world is primarily founded on Judeo-Christian principles. These principles, however, are not universally applicable and are merely a type of ideology known as *Religions of*

Difference; a metaphysic that grounds "the source of all goodness and truth in the transcendent, maintaining that humans are saved by a God outside rather than a God within" (Woodhead & Heelas 2000: 27). This ideological stance conflicts with the Mesoamerican view of the human being as fundamentally divine in nature and as a vehicle of direct consultation with sacred forces:

> "Mesoamerican peoples saw the human body as the nucleus and unifying body of the cosmos, which was permeated…with specific supernatural powers and entities. The human body was progressively filled - at conception, birth, the first exposure to fire and sunlight, and at points of special achievements in life - with powers originating in the celestial spheres above and in sacred events that took place in mythical time." (Carrasco 1990: 53)

Carrasco only acknowledges distinctions between ancient Mesoamerican religion and that of Religions of Difference when the attributes of the former correspond to the modern view of Native American spirituality as inferior. He concedes that images of indigenous peoples as "the wild man and the noble savage, were already deeply embedded in the European mind before Mesoamerica was discovered" (Carrasco 1990: 7).

Western researchers who ignore the significance of entheogens do so because they consider the experiences incited by these substances to be nothing but delusions. This is an illegitimate value judgement against the views of the people they are studying and displays the preformed assumptions that scholars have, prior to their delving into the subject matter. This is a clear demonstration of the very same Eurocentric bias that Carrasco denounces above, in his rebuke of the Spanish colonizers. It may seem like harsh criticism, but it is inexcusable in light of the blatancy of ritual entheogen use that has been featured in the above discussion. Adding to this image of the savage nature of ancient Mesoamerican peoples is the focus on human sacrifice and bloodletting. Of course, these ghastly ceremonies were certainly popular amongst Mesoamerican groups, but so were entheogen rituals, which are all but ignored in modern analyses. The choice as to which aspects of ancient Mesoamerican religion are discussed and which ones are ignored is entirely that of the researcher. Thus, it is suspect when an author chooses to focus on the violent features of a religion, especially when the description of such practices could be substituted for a description of entheogenic ritual:

> "Though it may seem strange to modern readers, bloodletting was not strange or unusual in Maya culture. It was described in the mythology of various communities, part of the public rituals of everyday life, and central to the ritual actions of the upper classes." (Carrasco 1990: 110)

One could replace the word "bloodletting" with "use of entheogens" in the above passage and it would remain true. If Carrasco is determined to enlighten his modern readers regarding the "strange" rituals of ancient Mesoamericans, it is remarkable that he would not mention the "strange" alterations of consciousness that they sought through the ingestion of entheogens.

The inclusion of bloodletting ceremonies alongside an omission of the entheophilic tendencies of ancient Mesoamericans reveals the prejudice that exists when modern scholars assess ancient ideologies. If those ideologies inspire the performing of rituals that are palpably abhorrent to modern readers, such as human sacrifice and bloodletting, they are included for shock value. On the other hand, when the ritual behaviours in question correspond to a more ambiguous moral issue being faced by modern society, such as the legal conflict between entheophobes and entheophiles, the matter is ignored altogether. The trouble is that the present legal status of entheogens holds them to be illicit, and any mention of them as safely enjoyable within a genuine religious context would imply that modern laws are unsubstantiated. To state that entheogens are an acceptable form of spiritual transcendence violates the established standards of modern Western morality. Therefore, it seems that evaluations of ancient Mesoamerican religion are expected to ignore the importance of these sacred substances in favour of a more acceptable image of the ancient Mesoamerican as a "noble savage:" their religious beliefs represent "a world that fascinates us, as it did the conquistadores and friars, by being so grotesque a reflection of our own" (Torrance 1994: 199). Ancient Mesoamericans are revered for the human qualities that we share with them, while at the same time, it is assumed that the modern citizen cannot learn anything from their barbaric religious practices organized around a warped sense of the divine.

Correcting the Oversights: A Revised View of Ancient Mesoamerican Religion

The above allegations are merely an account of how modern society's entheophobic bias obstructs the pursuit of an impartial portrayal of ancient Mesoamerican religion. Dobkin de Rios (1974) cites ethnographic data collected from the Human Relations Area Files at Yale by Richard Blum (Dobkin de Rios 1974: 161). Blum documents Western researcher's tendency to fail to notice the use of drugs that they themselves have not experimented with, which makes the oversights of archaeologists understandable:

> "It is apparent that observers from the outside (nonnatives) have been quicker to report their own reactions to drug use than to report the judgements of people within a society. Thus, we have observer assessments more often set forth than indigenous ones for all the drugs...Our conclusion from Tables 8 and 9 is that observers have been more sensitive to their own than to indigenous views of drug use within cultures." (Blum 1969: 147)

Blum is discussing ethnographic studies of contemporary cultures, and it appears that archaeologists are committing the same errors with ancient societies. When this entheophobic prejudice is exposed, it is imperative that the discipline amend its approach to the subject of study in order to incorporate the important facts that have been excluded.

This necessary reformation of archaeological approaches to ancient religion has still yet to be accomplished because "few large-scale archaeological studies have tried to explore the role of ideology in culture change" (Demarest 1992: 7). If the study of ideology and worldview is still treated as trivial in most archaeological surveys, this must now be rejected in light of the emerging truth that ideological structures dictate a culture's entire conception of the nature of reality. The problem of ignoring ideology stems from the inability of modern scholars to recognize that they have a worldview themselves; one that clouds their judgement when considering the vastly different worldviews of ancient cultures. For example, the concept of the duality of existence "in Mesoamerican thought...was not a duality of confrontation or opposition, such as is stressed in Western civilization from the 5th century B.C. onward, but a duality of complementary, interdependent, interrelating forces, each playing its respective role in the cosmic drama" (Labbé 1982: 35).

The Western concept of duality as "confrontation or opposition" speaks volumes about the modern failures to accept ancient behaviours that defy modern legal and moral presumptions. In the modern Western worldview, there is only the binary of "good" and "bad," and if it has been decided that entheogenic intoxication is "bad," then there is no need to discuss the ways entheogens have been conceived of as "good" in other cultural contexts because these cultures were obviously mistaken. It is acceptable to discuss human sacrifice and bloodletting because these practices have no place in modern religious life, but entheogen use is much more ambiguous. The uncertainty of moral codes against entheogens makes any discussion of them a challenge to existing laws. Apparently, the disinterest of religious scholars is stronger than their desire to fully understand the worldview of the subjects they are researching. It is hoped that the present paper has been successful in challenging this status quo of indifference and that it has opened new avenues of inquiry into the cognitive realms of entheogens, both in ancient and modern contexts. Future studies of Mesoamerican religion and worldview would be wise to incorporate the ritual importance of entheogens (for example mushrooms as *teonanacatl* "flesh of the gods"); for to ignore these substances is tantamount to neglecting to discuss the significance of bread and wine in Catholic mass.

Summary

The evidence for ritual use of entheogens exists in the archaeological record; but it is up to Mesoamericanists to permit the evidence to be taken into consideration. Iconographic remains reveal a large repertoire of bizarre visionary illustrations to which compelling interpretations were attached, usually of a divine nature. Ancient Mesoamericans possessed an ideological structure that greatly differed from the manner in which we view human existence today; a worldview into which entheogenic transcendence was readily integrated.

In this way, it becomes apparent that a major aspect of modern archaeological study is the examination of ourselves as modern civilization, relative to the values and moralities of foreign cultures. When we are confronted with the strange religious practices of prehistoric New World civilizations, it is threatening to discover that the standard moral system to which we adhere is merely an arbitrary ideological scheme that possesses no universal applicability.

Continued research into the ritual use of these substances by ancient Mesoamericans may reveal that their journeys into transcendent states of consciousness offered much more than delusional visions. Perhaps the phenomena that are encountered under the entheogenic intoxication offer repeatable, empirical experiences that can be analyzed as existentially-oriented science, ala Ernest Becker's Science of Man? (Becker 1968: 247, 1971: 158). Only through rigorous experimentation with the entheogens and the subsequent journeying into the otherworldly realms conjured by the ingestion of psychoactive chemicals can these methodological lapses be rectified.

Abstract

In 1957, R. Gordon Wasson, a professional banker and amateur mycologist, inadvertently launched a profound cultural change that has come to be called the Psychedelic Revolution, by publishing an account of his experience with a Mazatec shaman in Hautla de Jiménez in the mountains of central Mexico. The article appeared in Life magazine and was intended as publicity for his forthcoming Russia, Mushrooms, and History, in which he and his Russian-born wife Valentina Pavlovna pursued their lifelong fascination with their dichotomous attitudes toward fungi, which had led them to suspect a cultural taboo upon a sacred object. In 1968 he traced this taboo back to the Vedic Soma, which he identified as a psychoactive mushroom. The identification, if correct, implied that there should be evidence for a similar sacred role for the mushroom in other regions in antiquity where the migrating Indo-European people settled. In 1978, he proposed such a role for the visionary potion that was central to the mystical experience of the Greek Eleusinian Mystery, that was celebrated annually for two millennia at a sanctuary near Athens. The possibility that the ancient Greeks indulged in chemically altered consciousness is antithetical to Europe's idealization of Classical antiquity and the proposal was largely ignored. Mushrooms, however, were fundamental to social norms and religious observances in the celebration of Dionysus, and figured in other Mystery cults and in the foundational traditions of many cities, including Mycenae and Rome. The Soma sacrament as the Persian haoma was proselytized to the West by the Zoroastrian priests of Mithras and became a major cohesive indoctrination for the Emperors, army, and bureaucrats who administered the Roman Empire. It survived the Conversion to Christianity in the knighthoods of late antiquity and the medieval world, and was assimilated to the Eucharist of certain of the ecclesiastical elite.

Key Words: mushroom, ergot, Dionysus, Apollo, Mithraism, Renaissance art, prehistoric rock art.

Marital Crisis

In *Mushrooms, Russia and History* (Wasson and Wasson, 1957), R. Gordon Wasson and his Russian-born wife Valentina Pavlovna pursued their fascination with fungi, dating back to 1927, when upon their delayed honeymoon they first became aware of their dichotomous attitudes to something so simple and fundamental as mushrooms. The subject had never arisen in their five years of courtship. In a walk through the forested Catskills before supper at a friend's loaned mountain chalet, she discovered that the path was strewn with lovely mushrooms that he considered all loathsome toadstools. As a marital avocation while they each engaged in their separate careers, hers in medicine and his as an investment banker, they began collecting occurrences of mushrooms in European folklore, literature and art, which culminated in the deluxe two-volume compilation published just shortly before her death.

They had come to suspect that the difference, which they termed mycophobia and mycophilia, betrayed some religious taboo upon a sacred substance, traceable back to the earliest prehistory and somewhat mysteriously still surviving into modern times, perhaps as some kind of archetypal folk memory. The mushroom's sanctity is reflected in the absence of a name for something too sacred to name (Ruck, 2010). The natural growth, which can be classified as neither plant nor animal, is designated by metaphors or distanced as foreign words imported into the language. Among the mycophilic Slavs, there are more than forty designations, while the mycophobic Anglo-Saxons have only four, the foreign imports, fungus from Latin as metaphorically a 'sponge' and champignon from the French as a product of the 'field.' Mushroom is similarly an import from Late Latin through the intermediary of French *mousseron*. It, too, is ultimately a metaphor, derived from the verb *mussare*, which is onomatopoetic for making the sound of mooing or bellowing cattle, and hence a bovine zoomorphism of the mushroom (Ruck, 2015a). The only truly Anglo-Saxon name is the toadstool, describing it as a folkloric chair upon which is seated a loathsome toad, secreting the psychoactive toxin bufotenine, which it shares with certain fungi.

The intermediary status of the mushroom's classification, moreover, is reflected in its abundant occurrences in folkloric tradition, where it functions as the ultimate mediator between oppositional forces and concepts (Toporov, 1985). This dichotomy inevitably suggests the divide between the realms of life and death, and the mushroom lends itself readily to zoomorphism and anthropomorphic materializations as guides or modes of transport across the intervening frontier.

Psychedelic Revolution

This suspicion of the mushroom's primordial sanctity had led the Wassons in 1953 to the south-eastern Mexican village of Huatla de Jiménez in the mountains of Oaxaca, where they were introduced to the diviner Aurelio Carreras and his mother-in-law María Sabina. Gordon and Valentina participated as outsiders in a mushroom ceremony, an evening rite or *velada*, that had been kept as a carefully guarded secret of the indigenous people. The Wassons included an account of the events in *Mushrooms, Russia, and History*, but intentionally buried in the text, where it generally escaped notice and elicited little attention. Gordon innately abhorred sensationalizing his discoveries. In 1956, he read a short carefully worded paper before an association of Classical scholars in Philadelphia describing his experiences in Mexico, but in the ensuing discussion he intimated that the mushroom cult might shed light upon the Greek Mystery religion of Eleusis and the name of the city of Mycenae. One of the metaphors for the mushroom in Greek is *mykes*, as slimy and 'mucous.' Shortly later he received a letter from a friend of some thirty-five years advising him to keep his focus on Mexico and avoid implicating Classical antiquity. Nevertheless, there is a mythical account that a Greek hero Perseus plucked a mushroom at the site of the ancient city, and the monster Gorgon Medusa, whose head he similarly harvested as a golden apple with a pruning hook, was recognized in antiquity, in hermetic funerary contexts, as a mushroom (Ruck, 1978).

The pursuit of this same intriguing suspicion of a mushroom cult in Europe had already brought Wasson and his wife in 1952 to the Plaincouralt chapel in central France, where a Romanesque fresco of the Temptation episode in the biblical Garden of Eden had been suggested as early as 1911 as depicting the Tree of Knowledge in the guise of a psychoactive mushroom (Marchand *et al.*, 1911). They were advised, however, by a noted art historian that the resemblance was purely fortuitous and that medieval artists customarily painted trees in the stylized likeness of mushrooms. If they had looked across the Chapel at the opposing wall by the entrance, however, they would have noticed a mysterious scene that is not without relevance to the interpretation of the Tree of Knowledge. Another mushroom hovers in the air, in the guise of a red blacksmith's hammer, labeled by an inscription in dialectal Old French as the key of heaven. The fresco depicts the miracle of Eligius, the Chapel's namesake and patron saint. The mushroom is identified as the miraculous steed that has brought the Lord to the blacksmith's smithy to shoe His horse's single foot. Eligius is named as the patron of the 'Elect,' those privileged to see the Lord (Ruck *et al.*, 2007). The horse as the miraculous entheogenic transport occurs also in the birth of the flying Pegasus from the severed neck of the plucked Medusa's head. Wherever Pegasus touched down, a magical spring of inspiring waters burst forth, for which reason he is named as the 'Fountain Horse.'

Partly as publicity for the forthcoming publication of *Mushrooms, Russia, and History*, Wasson made public an account in the now legendary 13 May 1957 issue of *Life* magazine of his mushroom-induced visionary experience in 1955 with the Mazatec shamanic healer María Sabina, whose identity he attempted to mask under the pseudonym of Eva Mendez, thereby divulging and greatly popularizing the secret and inadvertently launching a flood of tourism to the remote mountain village and the ensuing cultural phenomenon that has come to be termed the Psychedelic Revolution. Albert Hofmann had discovered LSD in 1943, but it went without public notice until Wasson's magazine article, and within ten years *Life* published another article about LSD as a therapeutic drug that had gotten out of control. The patrician Wasson was a most unlikely person to play such a role and he distanced himself from the notoriety of the several leaders who rose to prominence in the resulting turmoil of recreational drug abuse, countercultural politics, and religious innovation.

Soma

Gordon retired from banking in 1963 and in the afternoon of his last day at work, he boarded a friend's merchant ship that sailed to the Far East, pursuant to the same theory of the mushroom's sanctity in the Old World that he and his wife had found among the indigenous peoples of Mexico. Two years later, he returned from the Orient and settled in Danbury, Connecticut, to work on the evidence he had gathered, resulting in the publication in 1968 of *Soma: Divine Mushroom of Immortality*, written with the aid of the young Indologist and Vedic scholar Wendy Doniger O'Flaherty, who now holds the Mircea Eliade professorial chair at the University of Chicago (Wasson, 1968). Wasson had heard of the reportedly intoxicating Soma as a teenager from his father, an Episcopalian clergyman, who wrote a book on God and alcohol and brewed spirits in his basement during the era of Prohibition.

Soma is an unidentified deified but not personified plant in the Vedic Sanskrit texts, carefully preserved as an oral tradition dating back as early as the mid second millennium BCE and committed to writing only after the rise of Buddhism, the earliest in the first century BCE, but mostly toward the end of the first millennium CE. The same sacred plant was known to the ancient Persians as *haoma* (sometimes deified), a dialectal version of the same name, described in the sacred texts of Zoroastrianism called the *Avesta*, which is so titled since they are the sole surviving examples of the Avestan language, a liturgical Old Iranian tongue closely resembling Vedic Sanskrit. The surviving texts where similarly transmitted by oral tradition dating back probably to the mid second millennium BCE, but finally committed to writing in the third century CE in the Sassanian era, which replaced the Parthian Empire and continued as the ruling dynasty until its overthrow by the Muslims in the mid seventh century.

Since Zoroaster is not so much a personal name as a profession meaning 'astrologer,' it is difficult to date the first occurrence of the priest who held the title, and some would place him a millennium later. The first Zoroaster (Zarathustra) is probably a figure of mythologized history. He revised the Hindu polytheism, elevating the solar deity Ahura Mazda ('Illumination Wisdom') to sole monotheistic primacy, with the heroic Mithras as mediator with the human realm. Many elements of the Mithras story coincide with the Greek hero Perseus of Mycenae (Ruck *et al*., 2011). Since the Zoroastrian priests or Magi proselytized their faith, their concept of monotheism may be the original source of the ensuing monotheistic religions, including the mid second millennium heresy of the Egyptian pharaoh Akhenaten.

Wasson proposed that the primordial botanical identity of this Soma/*haoma* plant was a mushroom, in particular the psychoactive *Amanita muscaria*, commonly called the fly agaric for its apparent ability to attract and kill flies. The physical characteristics of the divine plant as transmitted in the formulaic oral tradition are difficult to interpret since some may be metaphoric and others are open to a variety of linguistic interpretations, but remarkable for a plant, there seem to be no indications of a flower, leaves, or roots, attributes unique to a mushroom. The Soma ceremony was specifically intended to induce a state of intoxicated ecstasy that produced spiritual health, renewal, and immortality through mystical communion with deity (Spess, 2000), and was an entheogen. The theory had a controversial reception, with some proposing other candidates, most commonly cannabis, opium, and ephedra (Syrian rue) (Flattery *et al*., 1989). Residues of all three have been detected in archaeological remains of temples were the *haoma* ceremony was performed in sites as early as the mid second millennium BCE, as well as indications that the rite may have involved animal masks in the ritual, implying initiatory experiences of zoomorphic transmogrification (Bennett, 2007; Sarianidi, 2007). The cannabis was apparently used to fumigate the chambers. It is probably ephedra that is depicted in ancient portrayals of the Magi priests carrying the barsom bundle of twigs, and it still is used along with pomegranate in living Zoroastrian practice among the Parsis today, where the ancient *haoma* is called *hom*. There is also a tradition in contemporary practice that the ritual is purely symbolic, with only commemorative token sub-threshold amounts of the entheogen administered. It appears to be a customary tendency for religions to revise their history in denying the ecstatic nature of the original rites (Ruck *et al*., 2013), which in all probability have continued unabated, restricted for certain groups of the elite, or survive among marginalized and isolated adherents of the religion.

Syrian rue (*Peganum harmala*) is a bright green, dense, twiggy herbaceous succulent with conspicuous white flowers that grows in arid desert conditions. It has established itself as an invasive foreign import in the American Southwest. Its acts as a monoamine oxidase inhibitor (MAOI) and hence can function in the preparation of brews like *ayahuasca* to prevent digestive destruction, but evidence of its psychoactive properties in isolation is sparse and debatable. It is the source of the dye called Turkish red, employed in carpet weavings.

Wasson argued that although a variety of surrogate substitutes were employed as the tribal migrations moved into new areas that did not present a suitable habitat, the fungus best matched the characteristics as fossilized in the transmitted oral tradition, including its transfer and persistence into the excreted urine in a more potent potentiated form. This latter characteristic can be interpreted as culturally pejorative, but it is documented in Siberian shamanism which employs the *Amanita muscaria*. There is also a tradition of therapeutic urine drinking in Ayurvedic medicine. Wasson would later discover the use of the fly agaric and its urinous metabolite among certain indigenous people of the New World, as disclosed to him by Keewaydinoquay, a shaman of the Anishinaabeg (Ojibwe) of the region around the Great Lakes (Keewaydinoquay, 1984).

Mushroom Surrogates

In 1975, the art historian Stella Kramrisch, a specialist in Indian art and Hinduism, who held the professorship of South Asian Art at the University of Pennsylvania and was a curator at the Pennsylvanian Museum of Art, demonstrated that one of the first surrogates for Soma was a mushroom, not a psychoactive variety, but chosen for its symbolism as a mediator between death and spiritual transcendence (Kramrisch, 1975). Its corpse-like putrid stench was transmuted into fragrance in the firing of a ritual clay vessel, which represented the decapitated head of the deity Makha, analogous to the fungal materialization of the Greek Gorgon. One of the earliest depictions of the Gorgons occurs on a colossal seventh-century *píthos* urn that once served as a grave monument along the sacred road to the Mystery sanctuary of Eleusis. It depicts them with pots for heads, suggesting that the pot-headed females were anthropomorphisms of the potion that was the original content of the vessel.

In 1982, Wasson similarly discussed a non-psychoactive mushroom that appears to have been a surrogate for the original Soma. Gautama, the first Buddha (sixth to fourth century BCE), did not die, but by his own volition, it was claimed, since he had achieved such complete control over his physical body, he simply ceased living, the Great Demise, as it is called (Wasson *et al.*, 1982). As he was traveling with his entourage of monks to the place that he had chosen for this termination, he was offered hospitality by a blacksmith, who served them a meal of mushrooms. The role of a blacksmith as culinary host is an unlikely detail, except as mythologized history, and probably implicates the motif of the alchemical smithy (Ruck, 2015a). Brahmans can eat no mushrooms since they grow from unclean matter, but since all plants have a similar manner of growth, the prohibition betrays a probable taboo upon a sacred substance. Gautama decided, at this critical moment of his life, that he alone could break the prohibition and accepted this last meal, that he denied his entourage.

Eleusinian Mystery

After the publication of *Soma: Divine Mushroom of Immorality*, and before the appearance of such confirmatory evidence, it was argued that if the Soma/*haoma* sacrament was indeed fungal, there should be indications of a similar sanctity of the mushroom in other regions that the IndoEuropeans occupied in their migrations, beginning at the start of the second millennium BCE, away from the central Asiatic highlands that was considered their ancestral homeland, mythologized in Greek tradition as the Hyperborean country of the people who lived in a Apollonian paradise beyond the North Wind. Wasson returned to his intimation about the Greek Eleusinian Mystery and enlisted a team that included the Swiss chemist Albert Hofmann. In 1978, they published *The Road to Eleusis: Unveiling the Secret of the Mysteries* (Wasson *et al.*, 1978). It has been republished three times in commemorative successive decades. Mystery religions in antiquity involved something that the initiates were bound to keep secret. Plato describes the experience as a face-to-face visionary encounter with deity. The Judaic NeoPlatonist Saint Paul of Tarsus employed the same metaphor in describing what he called the Christian Mystery (Ruck, 2014). At Eleusis, this happened annually, predictably on schedule simultaneously for groups of several thousand candidates on a single night after the drinking of a special potion, whose ingredients were well known: kernels of barley and a common insecticide called fleabane, 'stirred' or mixed in an aqueous solution, for which reason it was termed the *kykeón* ('stirred with a circular motion,' cognate with 'cycle'). The simultaneous access to face-to-face mystical vision for thousands on a single night annually for over a millennium would be difficult to interpret as anything but an experience of shamanic communion with divinity induced by a psychoactive agent, and in this case the precise formula is an element in the recorded tradition.

The fleabane would seem the most obvious candidate for a toxic substance, and it had been proposed already as early as the nineteenth century. It, however, is not visionary, nor is its toxicity accessible in the miniscule concentration in the *kykeón*. Its role is symbolic, representing a wild plant, in contrast to the hulled barley groats, which are the products of cultivation. The fleabane, moreover, was personified as the water nymph Minthe, fragrant with the scent of mint (for which she is named), in which persona she was the perfumed whore of the netherworld lord Hades, abducted without the sanctity of marriage and hence the enemy of the matrimonial rite and civilized patriarchal culture. In Greek cultural tradition, the transition from matriarchal dominance to patriarchal revisionism marked the transition to Classical antiquity and the reign of the twelve Olympian deities, headed by the father god Zeus. Emblematic of that transition was the imposition of monogamous matrimonial control of the husband over his wife. The goddess Demeter vented her anger on this minty whore by grinding her with a mortar and pestle into a residue of despicable fragrance. In botanical nomenclature, fleabane is *Mentha pulegium*, where the specific name is an adjectival form of *pulex*, the Latin for 'flea.' In English it is commonly called 'pennyroyal,' where 'penny' is a corruption of *pulegium*. The honorific description of it as 'royal' (from the Old French *pouliol royale*) probably derives from its association with the Mystery.

In the year 415 BCE, it was discovered that numerous prominent citizens of Athens had been profaning the Eleusinian rite in their private homes by using the *kykeón* as a recreational drug with friends at their drinking parties. As parodied on the comic stage at the time, it was precisely evidence of the profane drinking of the potion that implicated the culprits. The accused were brought to trial and executed or else fled into exile, with the resultant confiscation of their properties for sale at public auction. The death penalty seems to have pertained only to divulging the secret of the Eleusinian Mystery, and specifically for profane use of the *kykeón*. The ancient Greeks had access to many intoxicating herbs and substances to flavor and fortify their wines, as was customary, and fleabane certainly was not worth the formidable hazards of breaking the prohibition against the sacred drink. Socrates was parodied on the comic stage at the time in Aristophanes' *Birds*, as profaning the Mystery in a rite of necromancy, in which he summons a troupe of fantastic anthropomorphisms that are easily identifiable as mushrooms. The most obvious is the tribe of Shade-foot creatures, who have but a single foot, with which they hop vigorously about until they tire, whereupon they fall upon their backs and slumber under the shade cast by the broad uplifted single foot that resembles a parasol (Ruck, 1981). Another of these anthropomorphisms was the Tongue-in-bellies, with a bulbous head that comprised their entire body, supported on their conjoined legs like a single support. They, too, not only are easily recognizable as fugal creatures, but in this configuration they blasphemously resemble the hermaphroditic dwarf who first served the specified *kykeón* potion as the etiology for its role in the Mystery initiation.

Ergot Mushrooms

The Wasson team demonstrated that the psychoactive agent in the *kykeón* was derived from the complex of numerous toxins present in ergot (*Claviceps purpurea*), a fungus that is parasitic on grain. Hofmann proposed that the active chemical was ergonovine, which is the only one that is water soluble and thus easily separable from the other toxins, some of which are potentially lethal and responsible for ergotism, causing gangrenous dermal lesions, hallucinations, and convulsive muscular twitching. Ergonovine, however, is only slightly visionary, if at all. Nevertheless, ergot often figured in medieval potions and the common nucleus of the ergot alkaloids is lysergic acid. In 2000, Peter Webster and Daniel Perrine revised the theory, identifying the active agent as ergotamine, a vascular dilator commonly prescribed in sub-threshold amounts combined with caffeine for the treatment of migraine (Webster, Perrine, and Ruck, 2000. Ruck, 2006). Ergotamine by partial hydrolysis (i.e., combining with water, but not a dissolution) in an alkaline aqueous solution yields ergine (LSA, lysergic acid amide), which is the same substance known as the visionary *ololiuhqui*, extracted from the seeds of certain morning glories in the shamanism of the Maya and Aztecs of ancient Mexico. LSD does not occur in nature, but LSA resembles it and is a natural substance.

The mycelia (root-like growth) of the ergot invade the parasitized grain kernels, causing enlarged purplish red sclerotia (hard bodies), protruding from the sheaf like cock's spurs, for which it is named (from the French *argot*). All mushrooms have a similar mode of growth, with the mycelia permeating large areas of ground, sometimes, as is the case with the *Amanita*s, living in mycorrhizal symbiosis with the roots of certain trees. The mycelium of the sclerotium, when the ergot falls to the ground and absorbs moisture, enters its fruiting stage, yielding tiny mushrooms visible to the naked eye, thereby identifying the ergot-infested kernel as apparently the seed of the otherwise seedless mushroom. Mushrooms propagate by microscopic spores, which were not detected in antiquity. Hence ergot mediates between the totally wild mushroom and the cultivated grain.

Primitive Grasses

The alkaline aqueous solution would have been produced by the addition of wood or bone ash to the water. This, also, represents a mediation, since the ashes constitute the residue from burnt offerings, the remains of sacrifice. The intrusion of the phallic plowshare into the symbolic vulva that is the furrow of the plowed field, converting it from the natural wilderness to cultivated arable land, is a sexual affront upon the sanctity of Earth, which must be appeased by a compensatory offering. In mythical tradition, the first plowman was sacrificed in the field he plowed, and the rite was repeated symbolically at each annual first insertion of the plowshare in a special field allocated for the inaugural plowing (Ruck, 2015a).

The sheaves of cultivated barley represent the cultivated antithesis of wild inedible grasses. Such edible grains were hybridized from more primitive grains. The most primitive is spelt (*Triticum spelta*), so named because it fruits with spikelets consisting of only two 'split' red grain kernels. These spikes obviously resemble the ergots of *Claviceps purpurea*. Hybridizing, moreover, is an ongoing process. Without continual human intervention, the hybridized grain would regress to its more primitive grassy manifestations. This is clear, for example, in the hybridizing of Indian corn by the indigenous peoples of the New World. If the cob falls to the ground, the next shoots that sprout from the entire ear will crowd each other out, so that their stalks grow progressively weaker and shorter, reverting to primitivism.

Weeds similarly infringe upon the healthy growth of the cultivated grains. A common weed in fields of grain is darnel or tares (*Lolium temulentum*). Its botanic nomenclature defines its species as 'drunken,' although it contains in itself no intoxicating chemical. Its reputation in antiquity as an intoxicant that induces altered eyesight derives solely from its common tendency to host the parasitic ergot, to which it is particularly susceptible. Darnel produced a cheap bread of proverbially poor quality, responsible for hallucinations. It threatened the cultivated crop, not only by competing for space, but also by contamination from its parasitic fungus. The ergot was called rust (Greek *erysibe*, Latin *robiga*) in antiquity, by which metaphor it not only designated its red color, but also likened it to the metallic oxidizing corruption that causes the iron tool to revert to the natural ore. It is hence emblematic of cultural recidivism.

The grain goddess Demeter/Ceres bore the epithet of *Erysibe* and wore slippers of reddish purple. In folkloric tradition, the ergot is metaphorically a pack of grain wolves, led by the grain Mother, rustling through the sheaves of fruiting grain, leaving the protruding infested kernels as 'wolf teeth,' that are also the iron teats of the goddess, who seduces children to come and nurse, rendering them maddened. A red dog was the annual victim of choice in Roman times to ward off the threatened infestation of ergot. The redness of the dog not only matched the color of the rust, but also associated it with the fox, which was interchangeable as a canine with the wolf, and hence the red dog represented also the primitive ancestors of the domesticated canine. There is also a mythical tradition that the rust scraped from a sacrificial knife was the antidote for the sexual impotency of a boy who had feared that he was the designated human victim.

The First Plowman

The potion of the Mystery initiation thus combined the wild and toxic fleabane, with its connotations of primitive sexuality, and the grain of the cultivated field. The connotations of the latter represent the grain goddess Demeter, who in the etiological myth for the Mystery is reconciled to the marriage of her daughter Persephone to her former abductor, Hades, the lord of the netherworld. The seed of grain must similarly be entrusted to the earth, in order to be risen. The mother relinquishes her daughter to the household of her husband, and the lord of the realm of death becomes related as an in-law to the celestial realm of the mother and her fellow Olympians. At the moment of the vision in the Mystery, the candidates, who had journeyed in the spirit to the netherworld, resurfaced in the initiation chamber at the moment that Persephone ratified her marital union to the otherworld by giving birth to the Mystery child, who was ultimately the first plowman. In mythical tradition, the celestial daughter had taken a seed of pomegranate into her body as she exited the netherworld, thereby contaminating her ethereal nature with physical matter, rendering her a creature that belonged to both realms. The pomegranate was named for its seedy bloody red matrix as the fruit of the menstrual 'flux.' Ergot figured in the pharmaceutics of ancient midwifery both to stimulate uterine contraction and to control postpartum bleeding.

The ergot as the cultivated fungus was the multifaceted mediating agent in the potion. The efficacy of fleabane as an insecticide probably commemorates the similar toxicity of the fly agaric or 'kill-fly' (fly-bane, French *tue-mouche*). All noxious insects, moreover, lend themselves to identification with malevolent spirits. There were two stages to the Mystery, however, for which reason the rite is usually designated by the plural. The Mystery, like all the Panhellenic sanctuaries, underwent a patriarchal revision in the seventh century, reinterpreting rites of the Bronze Age, dating back to the mid second millennium, and probably even earlier. The Lesser Mystery commemorated not this patriarchal revision and the consummation of the marriage in the birth of the child, but the unsanctioned abduction, which in the mythical tradition was occasioned by the picking of a wild plant called the *nárkissos*, so named for the narcosis that it induced. This rite was enacted six months earlier and involved not the mediating ergot fungus, but its primordial identification as the wild mushroom. The sole participant for the Lesser Mystery was the noble woman who bore the titular role of Queen of Athens, attended by her female sisterhood of assistants, who prepared her in a secret ceremony for her sexual engagement with the deity in the guise of the bellowing mushroom in a sacred chamber called the bull stall, opened just once a year for this ceremony. The role for the so-called Queen dates back to the traditions that predate the patriarchal revision of Greek culture occasioned by the advent of the deities in their restructured personae as members of the twelve Olympians.

Reception

The reception of *The Road to Eleusis* was generally unenthusiastic, with one eminent scholar entertaining the theory, probably merely as a curtesy to the Swiss Hofmann, but misunderstanding it and concluding that by all reports ergot poisoning was an unpleasant experience (Burkert, 1987). A recent book on the Bronze Age archaeology of the Eleusinian sanctuary (2015), in the obligatory initial overview of the religion, employs the word entheogen (which implies the acceptance of the concept that a psychoactive substance is animate with deity), but considers the argument speculative and concludes that the best explanation of the *kykeón* is that it offered a fortifying refreshment to end the daylong preliminary fast of the candidates, who had walked the exhausting twelve miles across a mountain pass along the Sacred Road from Athens (Cosmopoulos, 2015). A couple of groats of uncooked barley stirred in an aqueous medium with an insecticide is an unlikely nutritional boost. As recently as 2013, an article on ritual vision at Eleusis that promises a summary of 'learned reconstructions' of what it calls 'scopic regimes' includes no mention of entheogens or *The Road to Eleusis* (Petridou, 2013). A new textbook of Classical Mythology, makes no mention of the *kykeón* in its summary list of the different possibilities proposed for the Eleusinian Mystery over the centuries, and although it claims to place the ancient myths in the context of cross-cultural traditions and contemporary debate, it censors the subject of drugs and dismisses Mithras in half a sentence as something popular in the second and third centuries CE (Maurizio, 2016). Classical scholarship is resistant to the notion that drugs played a role in ancient society. Similarly, an exposé of drug expertise in Classical culture has caused its author to be shunned in the profession (Hillman, 2008).

Wine and Mushrooms

The mushroom, however, is not confined to the Eleusinian rite in Classical antiquity. It is fundamental to the symbolism and rituals of the god Dionysus, the deity of wine, drama, and the ecstatic communion with divinity. The ritual emblem for the mountain revels was the thyrsus, the hollow stalk or peduncle of a giant reed, stuffed with ivy leaves. Magical plants must be gathered with rituals that address their indwelling potencies as entheogens (Geniusz, 2009). This often involves fantasies of sexual engagement and birthing. The thyrsus is the receptacle for the gathered plants. Thus it was interchangeable with the narthex as a term. This latter lends it name to the giant fennel (*Ferula communis*) or narthex. The Latin botanical nomenclature classifies it as a 'rod,' and the Greek narthex has the obvious etymology as the 'narcotic container.' Several ancient compendia of medicinal herbs were titled *Narthex*. When Perseus plucked the Gorgon head at Mycenae, he placed it in a *kibisis*. This container has a similar significance. In ancient depictions, it is seen as a wide open-mouthed sack slung upon the arm. It is the bag, as still used today, for harvesting apples and other fruits, allowing the harvester to catch the fruits picked or pruned from the tree with the other hand (Ruck, 2015b). Because of its mycorrhizal symbiosis with the subterranean roots of its host tree, the *Amanita* mushroom was seen as a fruit of its tree, equally with the magical golden apples fruiting on its uplifted branches.

As with the wild growths that yielded to cultivation in the planting of barley and other grains, the grapevine had primitive antecedents. Most emblematic of these was the ivy, whose leaves and diminutive berries were intoxicating in their natural state, whereas the leaves and fruits of the grapevine are edible. Upon the crushed grapes, however, can be grown wine as a civilized intoxicant. The ivy leaves stuffed into the thyrsus represent the natural toxins that predate the evolution of viticulture. The other plants cited for the mountain revels had a similar symbolism. Among these are smilax (bindweed or wild morning glory) and bryony (wild cucumber). Like ivy, both physically resemble the grapevine and its clustered fruits, but they are toxic in their natural state. European folkloric tradition (Grimm, *Muttergottesgläschen*) identifies the morning glory as intoxicating, perhaps analogous to the *ololiuhqui* of the New World (Ruck, 2014). Sometimes the ivy atop the thyrsus/narthex is replaced with a pinecone. In this configuration, the rod symbolizes the ecstatic experience accessed by the gathered magical plants or entheogens. The pineal gland is so named for its resemblance to the pinecone and was identified in antiquity as the gateway of the soul for transcendence.

The grapevine, moreover, is obviously a cultivated vine since it requires annual pruning to fruit. In this regard, it is analogous to the olive, which is the plant most emblematic of civilization as evolved from chaotic primitivism. Hence, the olive branch is symbolic of peace, and a wreath of olive and an amphora of its oil were awarded to victorious athletes. Mythical tradition identified the olive tree as the transmutation of a mushroom transported from the Hyperborean homeland in central Asia, and it was commemorated as such in the annual secret botanical offering supposedly sent from there to the sanctuary of Apollo on the island of Delos (Ruck, 1983).

The fermentation process was correctly recognized as a fungal growth. Mushrooms themselves were called a 'fermentation of the earth.' Significantly in ordinary culinary nomenclature persisting as late as the fourth century CE, the stipe of the mushroom was called its thyrsus, with the cap representing the psychoactive plants stuffed into its stalk. In the case of the *Amanita* mushrooms, the toxins are largely present in the cap. Prominent in the metaphoric accounts of the mountain revels is the encounter with the mooing and bellowing bovine zoomorphic manifestations of the mushroom. A fragment of a fifth-century tragedy about the hero Perseus describes the ground bellowing with fruiting mushrooms. Whatever the revelers did on the mountainside, the drinking of wine was never an element. The rite symbolized the ecstatic rapture encountered through the wild plants that predated the evolution of the grapevine. The mooing bovines in myth, moreover, are always in heat, stung by the bite of the cow fly (*Tabinus bovinis*), who was personified as the spirit of their herdsman prodding them with the sexual lusting of the estrus, sending them into wild dancing (Ruck, 2015a). The tradition survived into medieval Europe, spreading northwards from the Greek settlements in Southern Italy, where it was known as the tarantella, the mad dancing fever precipitated by the bite of the spider. The ecstatic cows surrounded by the flies is a motif suggestive of the *tue-mouche*.

The grape bunches hanging from the grapevine were typically depicted as an analogue resembling the shape of a mushroom. Apart from the numerous poetic descriptions of the experience, there are irrefutably reliable historic accounts of extreme states of mental derangement as late as the Roman period. In graphic and literary depictions, the revel is permeated with hybrid creatures that are obviously visionary materializations from a non-ordinary reality. Among these are the ithyphallic goat-men or satyrs who engage sexually with the revelers and represent the attendants of the deity in his persona before the advent of viticulture. The grazing habit of the goat made it a threat to the vineyard, and hence an archetypal enemy of viticulture. Goats often figure as discoverers of the toxicity of plants as they tend to graze on all manner of wild plants, and the goat-herder, who lived in intimate close proximity of his animals, would have noticed the intoxication induced in his herd by certain wild psychoactive plants. Additionally, toxic plants impart the same psychoactive toxicity to the flesh of the animals that ingest them (Piper, 2013). The quail in particular were deemed drunken in antiquity because of their staggering gait and were noted as dangerous to eat since they often fed on plants that were lethal to humans (Ruck, 2015a). Appropriately the hybrid goat-men attendants of the old version of the god were suitable victims offered to his evolving persona as patron of viticulture and the civilized arts of the theater. Tragedy is so named as the honorific song sung for the slaughtered goat that is the archetypal enemy of the grapevine. In the ritual picking of the grapes for the vendange, the harvesters are depicted miming satyrs.

In Vedic and Avestan traditions, wine, although the most obvious intoxicating candidate, was never a surrogate for the entheogen, probably since it represents the antithesis of the wild mushroom. From the latest antiquity in the fourth or fifth century CE, Nonnus of Egyptian Panopolis in his *Dionysiaca* describes the fight between Dionysus, returning with his revel entourage from their conquest of the Indians of the Indus Valley, and the supporters of the Greek Perseus, a battle that epitomizes the antithetical contest between the wine triumphant and the aboriginal mushroom of Mycenae and the Hindu Soma (Ruck, 2014). The contest of Perseus versus Dionysus ends without victor since Hermes intervenes to reconcile the two brothers, both sons of Zeus. In this ultimate conflict, Dionysus employs the diamond as his weapon. It was reputed to have the power to repel all venoms, deflecting even the toxicity of the mushroom that was the Gorgon head. As an opponent of Dionysus, Perseus is fulfilling the same role as Pentheus of Thebes and Lycurgus of Thrace, who both opposed the advent of the civilizing gift of wine. Lycurgus, as the 'Wolfworker,' has a name that associates him with traditions of lycanthropy, and Pentheus, as the 'Suffering' complement to the Joy of Dionysus, was decapitated by the revelers, who placed his head atop the thyrsus as the analogue of the ivy and the other wild plants gathered on the mountainside amid the mooing of mushrooms.

The Wine Mix

Like the mediating potion of the *kykeón*, wine was a mixture that honored the toxins that predated viticulture by adding them to the vinous medium. Thus wine was customarily drunk diluted with three or four parts water, but even diluted it was extraordinarily potent. As little as a pint of diluted 4% alcoholic content drunk over a period of several hours in a succession of rounds could induce extreme intoxication. Only four rounds could result in mental derangement, and further drinking ended in a brawl. Alcohol itself was unknown as the intoxicant in antiquity. Distillation of liquids was not discovered until the fourteenth century CE, when the distillate was named alcohol by analogy to the process for metallic distillates and equated to the *quinta essentia* (quintessence, the 'fifth' quality) that Aristotle had postulated as the element of the celestial bodies that permeated matter as the spiritual soul (Ruck *et al*., 2012). This clearly derives from the ancient tradition that the wine served a sacral function. Since the alcohol produced by natural fermentation is limited to around 13%, after which concentration the aqueous environment becomes too inhospitable for continued growth of the fermenting yeasts, the toxicity of the wine was due to these fortifying herbal additives. These included even deadly poisons like hemlock in sub-lethal dosages and venom milked from serpents. This tradition survives in the modern Greek folk wine of *retsina* and in the demotic naming of the drink not 'wine' (*[w]oínos*), but the 'mix' (*krasi*). A recent archaeological discovery of an intact wine cellar from the mid second millennium BCE confirms the presence of psychoactive additives to the wine (Ritter, 2013). The tradition survives in certain rural wines of Europe today fortified with substances such as the dermal secretions of salamanders and toads.

The additives represent the toxins that predated viticulture. One of these additives appears to have been actually a mushroom. A Greek fifth-century red-figure *hydria* found in a cemetery of ancient Ainos (modern Enez, Turkey) depicts what is obviously a cultic scene, probably relative to the funerary rites performed for the burial of the deceased. A mushroom is highlighted as a special ingredient to be added along with other plants (perhaps bryony or smilax) to the mixing of a *píthos* urn of wine (Ruck, 2014).

Maronian Wine

The Thracian provenance of the *hydria* vase suggests that this particular wine was the legendary wine of Maron, a priest of Apollo and a descendant of Dionysus. In the Homeric *Odyssey*, Odysseus uses this wine to intoxicate the Cyclops Polyphemus. It was so potent that it would have required twenty parts of water for dilution. In the Roman period, a vineyard was still marketing a version of this heroic wine. On the testimony of the Roman governor of the region, it still required eights parts of water to be drunk safely. The blinding of the drunken Cyclops is depicted on the neck of the Eleusinian *píthos*, above the scene with the jug-headed Gorgons. The two scenes are probably complementary. A single tear in the shape of a mushroom drips from the eye of the blinded Cyclops. Both scenes are decorated with graphic designs termed *grecas*, which are interpreted as representations of entopic vision, the onset of chemically altered sight, where the eye begins to see the coursing of the blood flow across the retina (Wasson, 1986). Such whirling graphics are documented from prehistoric rock art. This mushroom-infused wine is particularly associated with Thrace, where archaeological evidence indicates that a mushroom cult existed dateable back at least to the generation before the Trojan War and the mythical tradition of Orpheus and the sailing of Jason with the troupe of Argonauts (Markov, 2008, 2014; Kiotsekoglou, 2014; Samorini, 2012).

In addition to the numerous megalithic natural rock formations that resemble mushrooms, a cave at Thracian Ismara/Maroneia that served as a sanctuary presents a fungal likeness in the configuration of its entrance, two adjacent openings like eyes with an overhanging rock configuration giving the impression of a stipe as nose supporting a mushroom cap as forehead, imparting a fungal face of the goddess to the mountain (Kiotsekoglou, 2014). The design resembles the fifth-fourth-century BCE marble bas-relief votive plaque of Eukrates found in the excavation of the Eleusinian sanctuary, the ex voto of a blind man who saw the vision; it depicts his eyes, with the goddess rising above against a hemispherical red cap as a sunrise. The same configuration of visionary eyes and fungal nose bridge occurs on silver and gold tablets found in the seventh-century Thracian sanctuary of Demeter at Mesimvria Zone. Persephone as a head rising from the ground was the essential vision at the Eleusinian Mystery sanctuary, and she is so depicted, attended by satyrs, on Greek vases. The fourth-century coinage of Thracian Maroneia employs the motif of the bunch of clustered grapes in the configuration of a mushroom. The fungal head of Persephone bears comparison to the prophetic head of Orpheus, of which there were several in caves throughout Thrace, from which could be read oracular responses, interpreted from the enigmatic magical markings on its surface (Ruck, 2014). Like Pentheus, Orpheus was decapitated in a Dionysian revel. Orpheus was cited as the founder of the Eleusinian rite, and although he belonged to the generation before the Trojan War in the mid second millennium BCE, he was also involved in the seventh-century patriarchal reorganizing of the rite, indicating that Orpheus is obviously a figure of mythologized history. There are two sources for the Mystery that combine and are reconciled in the patriarchal revision, one is from Minoan Crete of the goddess with the opium poppy, and the other is the Thracian Orphic origin, which involves the reciprocal complementary opposition of Apollo and Dionysus. Athens was a mythical relative of Thrace through the abduction of their princess Oreithyia by the north wind Boreas as she was gathering magical plants with a group of maidens called the Pharmacists.

The pre-patriarchal revision of the Eleusinian rite involves the wild plant cited as the *nárkissos* in the etiological myth of Persephone's abduction. The actual plant is probably the sea daffodil, *Pancratium maritimum*, which is illustrated in Minoan frescoes and a gold signet ring, depicting women with bee-heads gathering flowers in a visionary context, and on Mycenaean sacral swords. As its Latin nomenclature as 'allpowerful' (as in the athletic contest of the pancratium) suggests, the daffodil is psychoactive. It is not difficult to see that the flower resembles the vulva surrounding the reproductive stamens and pistil. By the Roman period, this daffodil had become identified as an ingredient compounded with olive oil in an unguent used by the Magoi Zoroastrian priests of Mithras to confer grace and power. This inevitably involves it in the tradition of the *haoma* sacrament, for which reason it was also identified as an orange-red flower. The opium of the Minoan goddess was similarly commemorated in the transition to the patriarchal revision as the pomegranate that inseminated Persephone to engender the Mystery child, since the red fruit of the pomegranate resembles the capsules of the opium poppy, similarly filled with its profusion of seeds.

Common to all the Thracian megalithic sites is their proximity to a water source, a river or a fountain spring, often haunted by a nymph, whose male mate is the river. A similar motif occurs at the Eleusinian sanctuary with the Sacred Well that lies beside the great portal to the sanctuary. The water from this well was spilled from two urns in the ritual of the 'full-pouring' (*Plemochóë*) as the inauguration of the Mystery, accompanied by the words written on the wall beside the double-gated entrance, 'Rain! Conceive!' Thus the goddess was invoked to birth the Mystery child that would culminate the ceremony.

The megalithic Thracian monuments often served as markers for organized necropolises or cemeteries. Many Greek and Anatolian phallic tombstones from all periods survive in the shape more correctly recognized as a mushroom. The asymmetry of the glans is never shown, nor the urinal duct nor the testicles, and the knob is often flat or spherical. Both the duct as an 'eye' and the testicles, in contrast, were elements commonly included in the sculptural and painted representations of the phallus and its metaphoric deployment on the comic stage. As the scholarly authorities on Greek burial customs concluded, none of these tombstones bear the slightest resemblance to the organ which the Greek artists knew so well and the only group of objects which they all can be said to resemble is toadstools (Kurtz *et al*., 1971). In fact, 'mushroom' appears to have been a metaphor for both the erect penis and for the burial coffin or the tomb.

A tombstone from Dascylion in ancient Bithynia on the shore of the Black Sea presents a particularly fine example of these ancient mushroom tombstones. The deceased Lysandra is depicted seated between two butterfly Psyche souls, like Celtic fairies, in a niche carved into the cap of the mushroom. Hermes as the escort of souls is carved into the stipe as a herm-pillar with penis, flanked by dogs or wolves.

Ionian Enlightenment

The Greeks obviously came into contact with the Achaemenid Persians in the sixth century through the expansion of their empire, which ushered in the period known as the Ionian Enlightenment and would culminate in the two wars at the beginning of the fifth century with the invasions of Darius and his son Xerxes ten years later. The sixth-century philosopher Pythagoras of Samos was initiated into the *haoma* rites while a prisoner in Persian-controlled Egypt. Ovid described what Pythagoras experienced as a journey in the spirit to the deities far-off in space to drink down with his eyes what Nature denies to human vision. In addition, disgraced aristocratic Greek politicians commonly sought asylum with Persian satraps and participated in their secret initiatory ritual (Ruck *et al.*, 2011). Their *haoma* sacrament, however, was known much earlier at least by the mid second millennium as *[h]ómomi*, which is the original for the moly (*mólu*) of the Homeric tradition, the plant that Hermes gave to Odysseus as an antidote for the drugs of the sorceress Circe.

On the comic stage of Athens of the Classical period, this Persian sacrament was well known and associated with Thracians. In Aristophanes' *Wasps* (422 BCE), it was visionary, inducing clairvoyance, and described metaphorically as a herded bull, and a lethal potion of its blood in a scene enacted by two Thracian slaves in an obscene routine of mutual fellatio, with the mushroom identified by its common metaphor as an erect penis whose ejaculate induced a Persian nodding sleep. It bellowed when strenuously erect with a snotty discharge, punning upon the mooing *mykes* and mucus (Ruck, 2012).

Among the Thracians, the mushroom cult was still empowering their kings as late as the first century BCE, as it did Darius, as witnessed by a Greek doctor assigned to the Persian court, in an intoxicated celebration of Mithras reserved solely for him. The cult also appears to have been the basis of lycanthropic rites binding their elite into a brotherhood of warriors. One of the Scythian contingents in the Persian forces was named the *Saka Haomavarga*, which means the '*Haoma* wolves' (Gershenson, 1991) The lycanthropic transmogrification was known to the Homeric tradition, as narrated in Odysseus' encounter with the Thracian horseman *Rhesus* in the *Iliad*. The event was also the subject of the Rhesus tragedy attributed to Euripides, when the dead horseman is cited as involved in Thracian Mystery rites (Ruck, 2014). Rhesus is probably a version of the Thracian god Sabazios or Zalmoxis. Darius' troops also knew of the mushroom's metabolite in urine. These are instances of a widespread cult better known among the Nordic berserkers of the medieval period, who materialized on the battlefield as wolves or bears, but which can be traced back to antiquity. The Emperor Trajan confronted it in his encounter with the Thracian Dacians, named for the 'wolf' and who bore into battle the ensign of their wolf-serpent Draco, bellowing in the wind. The Emperor was met by a Dacian shaman who read a warning to him off the markings on a mushroom cap.

Lycanthropy

The particular mushroom that fits the parameters of all these indications is the *Amanita muscaria*. It alone of the fungi is documented as inducing heightened physical strength and heroic fury in battle, and the scabby white remnants on its expanded cap allow a written message to be interpreted from its surface, and it alone is noted for its superior potentiated metabolite in urine. Many other Indo-European tribes were similarly named or associated with the wolf, and the common ritual indoctrination of the adolescent males into packs of wolves is documented among the ancient Spartans. The deity presiding over these packs as the assembly of his herd was the god Apollo, and he is the deity in Greek tradition involved in the motif of lycanthropy. As herdsman, he was invoked to protect the flock from the depredation of the wolves, but as the wolf god he also culled his flock as recipient of human victims.

In the evolution of Greek culture, Apollo was distanced from his darker persona and his lupine manifestations as the 'wolf' (*lykos*) were given a false etymology derived from the 'light' of the sun and its solar illumination. *Lykios* was fancifully associated with Latin *lux* for 'light' and Greek *leukós* for 'white,' and Apollo's epithet was explained as derived from the 'sun shining and making everything white.' The god's tenuous claim to the light of day, however, is reflected in the word for the dangerous marginal time of the dawn and the twilight as the 'wolf-light' (*lykóphos*). Similarly, the liminal threatening time when werewolves were abroad, the 'wolf-walk' (*lykábas*) was forced to mean the 'path of the sun' and glossed as a period of time, perhaps a year. The fulfilment of a period of time, however, implies termination or the temporal end, when the ultimate victim would be required. In the traditional antithesis between Apollonian and Dionysian modes of cognition, Dionysus assumes the burden of Apollo's lycanthropic involvement, freeing his brother to preside over the transmutation of toxicity into the entranced enthrallment of music and the metamorphosis of the deadly twanging of the thong of the bow and its poisoned arrows into the harmonized strings of the lyre. The words for 'arrow' and 'poison' are homonymous (*iós*) in Greek.

At Delphi, the original mid second millennium sanctuary was the Wolf Cave on Mount Parnassos, one of the largest subterranean cave complexes in Greece, with a succession of forty chambers leading deep within the sacred mountain. A rock formation within its entrance presents the likeness of a wolf. As the deity transitioned to his revised patriarchal Apollonian persona, the sanctuary was moved to its present location ever since the seventh century lower down the mountain, and the Cave above was entrusted to Dionysus or Hermes. The ecstatic revels there were still celebrated as winter rites of plant gathering well into Roman times, during which period Apollo would absent himself from the sanctuary. As a commemoration of his more ancient manifestations, he was forever linked, however, to the Wolf Cave since the oracular priestess would prepare herself for her ecstatic possession by the god in the below-ground chamber at the back of the Temple by bathing in the Castalian Spring that flowed from the subterranean lake within the Cave to surface at the base of the twin cliffs that loom above the present Temple sanctuary and she was named the Pythoness, after the former hermaphroditic serpent deity who once resided within the Wolf Cave as an oracle of Earth, instead of the Olympian Zeus as father of Apollo.

When it is not the brothers Dionysus or Hermes who assume the burden of Apollo's displaced darker person and his involvement with deadly or mind altering wild and primordial toxins, it is a beloved son like Asklepios, patron of druggist/doctors (*iatroí*), or Ion of Athens, eponymous ancestor of the Ionian tribal group, or Iamos, the founder of the brotherhood of shamans at the sanctuary of Olympia. The mythical tradition of them all involves them in the botanical lore of entheogens, with both Ion and Iamos providing opportunity for poetic elaboration on the etymology of their names and the motif of the *iós* arrow toxins derived from sacred plants (Ruck, 1976). This is true also of Apollo's homoerotic chosen victims, like Hyacinthus, Daphnis, and Cyparissus, who all metamorphosed into psychoactive or funereal plants (Ruck, 2015a). The homoeroticism was ritualized in the indoctrination of adolescents into the military packs of wolves. There was a tradition that even the Castalian Spring was named for the maiden who was the first of the many victims tossed into its waters from the twin cliffs high above.

Orpheus of Thrace was another of these beloved victims (Ruck, 2014). Despite his devotion to the solar manifestation of Apollo, he is named as the 'Orphan' from the light of his deity and was harvested as a primordial psychoactive anthropomorphism in the Dionysian revel. In the case of Kyknos (Cygnus), named as the 'Swan,' his grieving sisters metamorphosed into trees whose tears fell as lumps of amber. Such resinous discharge of trees was the commonly supposed origin of mushrooms, and all of these figures have a similar involvement ultimately with the fungus (Ruck, 2015a). Kyknos himself metamorphosed into the swan, which as Apollo's special bird, sings the swansong, the first and last utterance it ever makes, superlative, beyond all imagining, being the description of the paradise beyond this life to which the deity sends his victims.

Phrygian Cap

The lycanthropic motif is the origin of the Thracian/Phrygian cap. It provides the botanical name for the mushroom's cap as the *pileus*, implying an anthropomorphized creature beneath it wearing it as its hat. It had a long continuance through medieval and Renaissance tradition until modern times as a marker for initiates into the secrets of the ancient Mysteries (Ruck *et al*., 2011). The Phrygian cap was originally a fox pelt, complete with snout and ears, sometimes the entire animal (Ruck, 2014). The Thracian reveling plant gatherers of the pre-viticulture Dionysus were named for this pelted cap. The fox is a canine analogue of the wolf, and its pointed snout and red color were stylized in the drooping felt versions known as the liberty cap, awarded to liberated slaves, although the original liberation freed the initiate from the restrictions imposed by the human condition.

The red cap is as ubiquitous as the little creatures that materialize in the lore of Europe, most notably in the tale of 'Little Red Cap' (*Rotkäppchen*), known in English as 'Little Red Riding Hood,' and the episode of lycanthropy and with a similar ultimately ethnobotanical referent (Ruck *et al*., 2007). The English title predates the Grimm brothers' collection, and the 'riding hood' as a term for the Phrygian cap indicates that the heroine of the tale is on a journey that will culminate in sexual awakening with her aged grandmother as initiator and a lupine transmogrification in the belly of the devouring wolf. Digestion is a metaphor with alchemical implications of transcendence. Nineteen-century illustrations of Little Red's encounter with the wolf often include the fly agaric growing in the woodland scene, which would seem to indicate that the illustrator was privy to the secret.

Eggshells

The etiology of the red cap was explained as the remnants of the egg from which the twin Dioskouroi (Dioscuri) were hatched, each wearing a half shell. As such they were cited as patrons of the Mystery of the Great Gods (*Mégaloi Theoí*) of Samothrace, which was second only to the great Eleusinian rite in antiquity in reputation and importance. The twins were inseparably bound to each other. Although only one of them was immortal, the son of Zeus, while the other was mortal, the son of their mother Leda's husband Tyndareus, they vowed to share their dual fate, dying together on alternate days, and returning the next. They obviously imply a similar aspiration for the initiates as they sailed the perilous voyage through life, and hence the twins were cited commonly as patrons of seafaring, although their true significance refers to a metaphysical journey. They could be represented as two adjacent *amphorae* vessels of the Mystery's Thracian wine of Maron, especially potent from its fungal additive, whose toxicity is indicated by the serpents entwining the vessels. Numerous drinking cups that were the property of the priesthood survive in the ruins of the Samothracian sanctuary, leading the archaeologist who excavated the site to conclude that excessive drinking to the point of intoxication was clearly an element in the Mystery (Lehmann, 1954). Similar rites involving the same complex of deities occurred elsewhere, and drinking from special sacred vessels was always an element, with the cups then shattered to exclude them from later profane usage.

The Dioskouroi could also be depicted as two posts, representing the half eggshells of the curved red caps, joined by a crossbeam, as if they were Siamese twins, before their separation. In this configuration, they resembled their cousins, the Moliones, who were similarly hatched from a single egg, but joined at the waist as Siamese twins (Ruck, 2015a; Ruck *et al*., 2001). They are the mythical prototype of the spherical primordial humans that were sliced in half like an egg in Aristophanes' tale of the Hermaphrodite in Plato's *Symposium*. This tradition of the Siamese twins encodes another attribute of the *Amanita muscaria* that identifies it as the magical plant that sprouted from the liver of the tormented Titan Prometheus that served as food for eagles (Ruck, 2015a). Eagles' fare is a version of raven's bread, a metaphor for the mushroom, because of the birds' fondness for the *Amanita* (Klapp, 2013). As food for the thunderbird, it occurs also in indigenous North American tradition. Medea plucked the Promethean mushroom to compound the dermal unguent that she entrusted to Jason (Iason) to fortify him with the superior strength that allowed him to yoke the fire-breathing bulls, with which he plowed the field to sow the primordial toxic crop that sprouted from the fangs of a monster serpent. He is named Iason, like Ion and Iamos, for his involvement with this *iós* toxin.

Dumbbell

Medea cut the root of this Promethean plant amid the sound of bellowing and mooing from the earth, and it is described as growing with a double stem (*kaúlos didúmos*), not a branching stem. It is, more exactly, a 'twin' stem. The epithet of the Dioskouroi was the 'Twins, '*Didúmoi*, and they became the constellation Gemini. This encodes a riddle since no plant grows from the earth with a twinned stem, side by side, except the *Amanita*s. As the subterranean nodule or egg that develops from the mycelium into the fruiting mushroom expands, the stem or stipe/trunk extends in both directions, pushing the base apart from the cap, shattering the eggshell, producing a shape like a dumbbell, easily recognizable when plucked from the ground. It is also the traditional shape of the sacred thunderbolt that inseminated the mushroom at its conception from the heavens, meshing celestial fire in the wet matrix of matter. The thunderbolt of Zeus in this dumbbell shape, often with conventional lighting flashes attached and sometimes with wings, is the Greek version of the *vajra* thunderbolt of Indra, and in Buddhism it is symbolic of the thunderbolt experience of *Bodhi* or 'awakening.'

The Mystery child could be depicted also as emerging from the cosmic egg, pushing the two hemispherical eggshells apart, marked with the signs of the Zodiac as indication of the transcendent return to the celestial realm (Ruck *et al*., 2011). This double-stemmed herb of Prometheus, moreover, was the same color as the plant involved in the rituals of the Wolf Cave at Delphi and in the birth of Ion of Athens in the cave beneath the Acropolis. In this version, the plant goes by the name of Krokos (crocus), chosen for the phallic appearance of the blossom as it emerges from the earth. In mythical elaborations, Krokos was anthropomorphized as another adolescent who fell victim to the deity, and he was linked with another lover called Smilax or 'bindweed,' and they both represent the primordial plants that predate the evolution of viticulture. The crocus is analogous to the *nárkissos* and Minoan frescoes depict both monkeys and maidens gathering it. The monkey was emblematic of little primordial humanoids, and they were mythologized in the figure of the Kerkopes, whose name designates them as having the appearance of a 'tail,' indicative of their fundamental phallic identity. They survived in European folklore as the German *Kobald*, the French *gobelin*, and the puck of England, ecstatic mischievous little creatures, like fairies, in the entourage of the Dionysian plant-gathering revel.

Phallic Grotesqueries

Although the Dioskouroi were depicted as idealized youths, there were analogues of them in the Mystery of Samothrace that made them dwarfish and ithyphallic, since the cult of the Great Gods encodes the secret that the divinities were actually great in power, but the opposite in stature. The Dioskouroi were warriors and a fanciful version of them occurs as the *Kaulomykétes*, little men comprised of the 'stem' (*kaúlos*) uplifting the mushroom caps as a shield above their heads. These creatures must obviously be no bigger than mushrooms themselves. This stem, moreover, was a common metaphor for the erect penis, which reduces the entire anthropomorphism to its phallic function as the 'mushroom' penis. As *Kaulomykétes*, the little warriors have an asparagus stem as their sword, a vegetable of choice for its phallic thrust and its noticeable effect on the scent of the urine (Ruck, 2015a).

In this configuration with uplifted shield, the Dioskouroi mushroom warriors are analogous to another of their anthropomorphisms in the Mystery of the Great Gods as the Corybants ('helmeted-dancers') and the Curetes ('boys'). Although they, too, are idealized youths, they sprung from the fingers of Rheia, the mother of Zeus, as she grasped the ground in labor. The Cretan Caves on Mount Dicte and Ida, where Zeus was born, were equated with the sacred Zerynthian Caves on Samothrace and throughout Macedonia and Thrace as sites for the Mystery. The Corybants danced ecstatically, clashing their shields to drown out the sound of the baby's birthing and are typically depicted with shields uplifted and standing on a single foot. The pose is symbolic and it appears also in depictions of Mithras, where it encodes the same fungal identity of the *haoma* sacrament (Ruck *et al*., 2011). Mithras himself is traditionally attended by two male torchbearers, who always stand with their legs crossed, making them essentially one-footed and also symbolizing the entrapment of the celestial fire in matter, emblematic of the sacred mushroom. The Dioskouroi often are depicted with these same crossed legs. The torchbearers always depicted with one holding his torch thrust downward, the other upward, on either side of the Cosmic Bull, signifying the entrapment and liberation of the celestial fire through the sacrifice of the bull.

As finger creatures from the digits of Rheia, plucking plants in ritual mimesis of birthing, the Corybants are analogues of the tiny creatures named for the 'fingers' as dactyls. They often occur as a brotherhood of five, African pygmies, a fistful of them, from Latin *pugnus*, cognate with pugilist for 'boxer,' which is probably responsible for the portrayal of the Dioskouroi as boxers, although the Greek *pygmé* is the measure of a forearm or cubit, making them approximately a foot tall. The actual five-foot Pygmies of Africa were named after their mythological etiology and were considered sacred and much in demand as holy magical curiosities by the Egyptian pharaohs. This tradition continued through the Renaissance in Europe with the dwarves in the entourages of the royal families and in folkloric heroes like Tom Thumb, only so big as a thumb, and swollen like the penile member that is his essential identity (Ruck *et al*., 2007).

Another version of them in the Mystery was the black-skinned *Kábeiroi*, misshapen dwarves, the males with prominent erections. The sorceress Circe was depicted as such on surviving vessels from the Mystery as she compounds her potion for a *Kabeiric* ithyphallic Odysseus, sailing on a drunken amphora of the special wine of the rite (Ruck, 2015a). On the stage in Athens, the tragedian Aeschylus depicted the *Kábeiroi* in an orgy drunk on the wine of Maron in his satyr play. In Aristophanes' *Lysistrata* (411 BCE), the divided chorus of combatting males and females was staged as dual troupes of *Kabeiric* grotesqueries in a parody of the Mystery as practiced on the island of Lemnos. The *Kábeiroi* were also imagined as crabs, wielding their pincer claws as henchmen of Hephaestus in the metallurgical volcanic crucible of alchemical transmutation, forging a cure for ordinary blindness. The metallurgist's pincers were called 'crabs' and Aristophanes staged them in the *Wasps* (422 BCE) as pubic lice impersonated by children, obscenely dancing around the erect phallic personification of the Persian *haoma* sacrament, with which the comedy had begun (Ruck, 2012). As the mythical figure of the Crab, the creature was involved in the motif of the toxins that anointed the poisoned arrows of the hero Heracles, and it was ultimately transported to the stars as the constellation of Cancer (Ruck, 2015b).

Penates

These Mystery figures were associated with the Etruscans, who were thought in antiquity, perhaps correctly, to have been Trojans who passed though Samothrace on route to Italy. *Kábeiroi* may be an Etruscan word, and inscriptions in an Etruscan-like language are preserved on Lemnos. On Samothrace, portions of the liturgy were recited in a no-longer comprehensible pre-Greek or Pelasgian tongue (Cooper, 2000). These creatures of the Mystery were known to the Romans as the Penates, idealized adolescent males in historical times, although the original Penates that Aeneas carried out of Troy to the banks of the Tiber were probably *Kabeiric*. They were preserved there in historical times, probably as pious forgeries. It is significant, however, that the Penates as displayed in private houses were always statuettes or figurines, little people. The twin posts of the *Dioskouroi* joined by the crossbeam could be interpreted as an iconic glyph of a shrine or of the household placed under their guardianship, in which form the Spartans carried the emblem into battle as a standard in front of their army. The glyph was called the *dókana*, derived from the Greek verb *déxasthai*, meaning 'to receive' (Waites, 1919). As a shrine, it represented the opened tombs in Sparta that hospitably received and released the twin brothers on alternate days, and it symbolized the brotherly love, mortal and immortal, that spans this world and the grave, open to receive and release its guests, binding the household to the other realm, under the sacrosanct obligation of reciprocal 'hospitality,' *philoxenía* or *theoxenía*. The Dioskouroi were summoned and expected to materialize as guests at the table of their host (Klöckner, 2010). A similar linkage of guestfriendship (*xenía*), the reciprocal role of host to guest, was the ultimate benefit promised to the initiates at Eleusis.

The Roman Penates were guardians of the household's store of provisions in the innermost recesses of the home, the *penus*. A small portion of the meal was thrown on the fire as a token offering at every dinner as a sacrifice to remove the taint of primordial toxicity, after which the attendant slave would announce that the food was now safe to eat. The etymological derivation from the 'innermost' was more significantly connected in antiquity with their phallic identity and the motif of 'penetration' into the secret shrine of the household's goddess of the central hearth and into the inner core of life, with connotations of sexuality and mystical vision (Bonnefoy, 199). The toxicity of the creatures that sprouted from the primordial intrusion of the plowshare into the vulva of Earth was mythologized in the tales of the Sown Men, the autochthons who sprouted from the serpent fangs. They were tricked into internecine strife, a battle that blamed them for their own fraternal sacrifice, leaving only a few remaining, whom the plowman took into his own family as in-laws.

Tages

The Etruscans had their own version of the autochthonous creature. This was the tiny male named Tages, who popped up out of the ground in the path of the plowman and founded their religion. People gathered around this miraculous apparition and in the presence of the entire populace of Etruria, what it said was written down from dictation as the holy book that was the foundation of the Etruscan science of divination. His father was Genius, the *creator spiritus* or 'creative spirit,' sometimes winged fairylike, that personified an individual's manifestation of divine nature, resident in all aspects of creation, including the observances of communal life, the norms of civilization and its ritual procedures, linking them to the realm of nature and the cosmos (Grummond, 2006). Sometimes Tages is depicted as just a talking head emerging from the ground, obviously not yet capable of walking. All the autochthons display a similar ambulatory difficulty, indicative of their botanical identity, and if they walk at all, they tend to be lame or have but a single foot (Lévi-Strauss, 1955). As a talking head, Tages resembles the prophetic heads of the harvested Orpheus, and it is likely that what they said by dictation was read off the markings on their heads, like the message encoded on the mushroom of the Dacian shaman, presented to the Emperor Trajan. Tages usually wears the conical red Phrygian cap, and his basic identity is phallic, wearing a pouch as a locket around his neck containing phallic objects as a protective amulet, such as was customary for Roman male children until puberty, and then stored as a memento and brought out again for display on special adult honorary occasions.

Tages is the Latinized version of his name, which in Etruscan would have been Tarchies, probably a variant of Tarchunus, the Etruscan version of the Latin Tarchon, the legendary founder of the Etruscan city of Tarquinia, north of Rome. Tarchon was the name of the plowman, which makes him identical with Tages, and they were customarily portrayed together, the little talking head and the plowman recording the dictation. The ancient Etruscan cemetery at Tarquinia dating from the eighth century BCE contains a number of stone urns containing the cremated remains of the deceased, covered with hemispherical covers, presenting the likeness of mushrooms. It is the pattern copied in the more elaborate Etruscan multi-chambered tombs, which are cylindrical and topped with a grassy mound, like the Mausoleum of Augustus, which are probably mushrooms with expanded stipes. As philhellenes, the Etruscans often placed Greek vases as funerary offerings with the deceased in these mausoleums. The placement in the tombs allowed them to survive until modern times. The vase depicting Perseus with the decapitated head of the Gorgon Medusa is one such vase. Mushroom shapes are prominent in many of these. One of them is a large fourth-century BCE platter, over two feet in diameter, depicting the abduction of Persephone, with the rim decorated in raised knob-shaped mushrooms, which are not intended as handles (Ruck, 2014).

The special knowledge that Tages entrusted to the Etruscans was divination through the inspection of the liver of a sacrificed animal, haruspicy (hepatoscopy). It is an art of the greatest antiquity that can be traced back to Mesopotamia and even earlier, with references both in the Bible and in Homer. The priest inspecting the liver is traditionally depicted with wings, indicative of his shamanic rapture, and standing with one foot raised and resting on a rock, mediating between earth and the celestial realm, and Etruscan mirrors portraying the ritual often have the winged Genius on the base handle.

Cosmic Liver

Since the liver is essential for life, the largest and weightiest of the entrails and containing the greatest amount of the life force in the form of blood, it was considered the center of personal existence. The markings of the universe could supposedly be read off its surface, and thus it was a microcosm of the vitality of the celestial realm. The haruspex, by manipulating the liver, could also influence events in the cosmos that it mirrored. Such power was seen as a threat to the established order, and astrologers were on occasion either banned or executed by a succession of Roman Emperors. The liver as food for the eagle was the organ that was the site of the daily torment of the chained Titan Prometheus as punishment for his creation of man and the theft of fire. He is the mythical prototype of the clairvoyant seer, named for his 'Fore-thought' or prognostication. The liver was considered the primordial organ of the body, the part that developed first in the fetus, around which the rest of the person grew in the womb. It is the organ that functions in hemolysis, the cleansing of the blood from toxins, and thus it is a motif in botanical agencies for shamanic rapture. Although it is unlikely that the ancients knew of the filtering function of the liver, it was thought to be the organ through which the digested food from the stomach entered the bloodstream. The liver would have the highest concentration of psychoactive toxins, reabsorbing what the kidneys did not eliminate into the urine. The theft of fire, hidden in the narthex, involves the motif of root-cutters and herb-gatherers. The bitter brownish or greenish-yellow secretion of the liver called bile or gall (Latin *bilis*, Greek *cholé*, both derived from the Indo-European root *ghel*- for 'shine,' yellow like 'gold,' with which it is cognate) is another element in this motif. It is listed as two of the basic humors of the body (melancholic, choleric) and was associated in Roman thought with rancor and madness. 'Gall' was further implicated in the motif of psychoactive toxins by its association with the venom of serpents, which it was thought contaminate plants by contagion. Eating your enemy's liver was equivalent to mastering his soul.

Indigenous Foreigner

The shared identity of the Tages and Tarchon, the autochthon and the plowman, makes the founder consubstantial with the foundation. This is often expressed by the motif of the founder as supposed foreign immigrant encountering himself in the personae of the indigenous autochthons, like Cadmus at Thebes, who slew the serpent to plow the field with its fangs and subsequently metamorphosed himself with his bride into serpents. In the exemplar of Prometheus, the creator of man is consubstantial with the primordial organ of the prognostic liver that serves as food for eagles, which implies that he is a fungal personification. In Corinth, there was a tradition that in former times men had indeed first sprouted from the ground as mushrooms swollen after a rainfall. On the comic stage of Athens, Aristophanes costumed Prometheus in the *Birds* (415 BCE) with his phallus unfurled as a parasol, in imitation of the Shade-foot fungal anthropomorphism (Ruck, 1981). There could not be a more blatant revelation of the mushroom's central role in Greek tradition as the origin of all human intelligence and science, as catalogued by the Titan himself in the *Prometheus* tragedy ascribed to Aeschylus.

The mythical tradition of these little fungal creatures mediates the opposition between the realms of life and death in terms of the relationship between the primordial toxicity of the wilderness and the inaugural plowing of the agrarian field to plant the crops of civilized culture. Hence, it is fundamental to the founding of cities, an accord and covenant with the forces of primitivism. In narrating the arrival of the Trojan Penates to Italy, Virgil in the *Aeneid* was required to include a bizarre and enigmatic event recorded in the supposedly historical accounts. This involved the fungal identity of the plant most emblematic of the wilderness and as the *haoma* sacrament, most indicative of the transcendence toward culture (Ruck *et al.*, 2013; Ruck, 2015a).

Fairy Tables

It was predicted that Aeneas and his men would be cursed to endure such extreme hunger before they founded the new settlement in Italy that they would be forced to eat their own tables. The curse was an item of arcane tradition, a brief riddling mention of a weird mythical event apparently recorded in some now-lost work preserved in the Alexandrine library, probably elaborating some ethnographic anthropological motif, which was a particular interest of the scholar-writers who presided over the library and its vast collection of texts. Virgil discussed it with historians among his friends, who were puzzled by its meaning. He, however, was required to include it, and he figured it out and transformed it into an innocuous surrogate, as suited the rational sobriety promulgated by his patron Augustus as a national agendum or at least as the virtue he claimed as destined Emperor.

The mythical precedent was the repulsive tables of food defiled by the excrement of the Harpies like a swarm of monstrous flies, which was all that the starving Thracian prophet Phineus had for food, but which also was responsible for his gift of clairvoyance, which to say, that the food was psychoactive or an entheogen. The Harpies were imagined to materialize as a whirlwind and to snatch people away, hence their name a 'Snatchers,' sometimes demonized as ornithological human hybrids, but also portrayed as beautiful women with wings. Like the fairies of Celtic lore, they were accused of stealing people away to their netherworld realm on a blast of wind, called an elfin eddy. A person was apt suddenly to disappear from sight in this world, in a fit of rapture, possessed in the clutches of these ravishing Harpy virgins. Hence, a visitation by the Harpies had orgasmic connotations of shamanic ecstasy, which is the common metaphor in Greek for mystical vision. The edible tables are the folkloric motif of the fairy tables, a loathsome slimy red tabletop, supported on a pedestal and spread with the dainty morsels of the scabby white remnants of the *Amanita*'s shattered universal veil, and swarming with the flies attracted to the contaminated feast. The fairies also scatter round breads about the ground, but the food is cursed and should never be eaten, except in the times of severest hunger. Conversely, a piece of bread thrown on the ground was the surest amulet to ward off a blast of the dangerous kidnapping wind.

Virgil saves his hero by a ruse of paternal piety from partaking in the ecstatic feasting required for the primordial encounter with the new land that he as founder must settle. Without knowing what he is doing, he follows the precise directions of his putative divine grandfather Jupiter/Zeus (the father of his mother Venus) as delivered from the oracle at Dodona, spreading rounds of primitive spelt bread upon the ground and heaping them with wild fruits, and after they have eaten them, the curse becomes merely a joke, as his son Iulus (the supposed ancestor of Julius Caesar) notes that they have eaten their tables. The only way to thwart a true prophecy is to enact it in some other way, and this Aeneas, pious as ever, has blindly done. There was no shortage of proper tables for use as equipment aboard his ships and thus the novel banqueting protocol was merely his uncomprehending adherence to the directive from Dodona.

Mithraism

The *haoma* sacrament was directly introduced into Rome in 69 BCE, just the year after the probable date of Virgil's birth, when the general Pompey took the Cilician pirates captive to the city of Rome. As a young man, Virgil probably knew of Mithraism, and a hundred years later, by the time of Nero, there were already well-established Mithraic lodges in the city for him to be the first of the almost continuous succession of emperors to be initiated in what was called 'magical dinners' (Ruck *et al*., 2011). Earlier versions of the initiation lodges were already prevalent in Anatolia, traceable back to well before the sixth century. The lodges were small subterranean chambers, preferably with a natural source of water, imitating a cave in which the hero Mithras slaughtered the Cosmic Bull, and the initiates, like Pythagoras, experienced a transcendent journey of the spirit to the rim of the universe. The lodges spread throughout the Empire in Europe, Britain, North Africa, and the Near East, although rare in Greece since they already had similar rites associated with Perseus. It indoctrinated most of the emperors, and the army and male bureaucrats who administered the Empire, until the conversion of Constantine, who was himself probably an initiate. The seven sacraments of the Christian Church are modeled on the seven stages of the Mithraic rite. The sixth stage elevated the candidate to the persona of the Apollonian Solar Charioteer as the adoptive son of the Father, which was the seventh and highest grade. As adoptive son, he was pure from the Gnostic contamination of physical conception, correlating with the Platonic ideal of spiritual paternity, a role that Christ also played in the heresy of Adoptionism. Hence, women were excluded from membership in the lodges. It was the Charioteer's role to be offered as symbolic victim to usher in the final apocalyptic Conflagration, after which the cosmos would be renewed as the new age. This is obviously similar to Christ as sacrificial mediator of his Father with humankind, and the Second Coming, which was originally expected within the lifespan of the first disciples.

In Mithraism, the Solar Charioteer and the Father ratified their relationship by a banquet upon the meat of the Cosmic Bull in the form a loaf of bread, marked with a chiastic cross, representing the solar ellipse, which is segmented by the astrological glyphs of the zodiac, intersecting with the celestial equatorial belt, indicating that the bread was meant to symbolize the cosmic sphere, as something heaved up by the fungal leavening to form the heavens. The loaf of sacramental bread thus has the same symbolic relationship to the cosmos as the prognostic liver. The chiastic design was copied in the bread of the early Communion rite of Christianity. Virgil's 'fatal crusts' of round bread in the episode of the edible tables were similarly marked into quadrants, suggesting that the poet may have been a Mithraic initiate. The cross comes to signify the zodiacal marker for the sign that will preside over the new age occasioned by the precession of the equinoxes caused by the wobble in the Earth's axis, ushering in a new age about every 26,000 years. The cross thus also marks the time for the cosmic sacrifice, as time moved from the constellation of the zodiacal Bull Taurus to the Age of the Lamb Aries, and thus it also had implications for the cross of the Crucifixion. Aries as the Lamb also added new spiritual implications to the interpretation of the mythological tradition of Jason and the quest for the Golden Fleece of the sacrificed ram (Ruck, 2015a).

Raven's Bread

The Mithraic bread was served to the two banqueters by the Raven, which was the lowest and first grade in the initiation, representing the sinful entrapment of spirit in matter, which would be released in the final stages of initiation. At the second stage, the initiate became the bride of the Father. The bread was Raven's bread, the common metaphor for the *Amanita muscaria* (Klapp, 2013), and called a bread by analogy to the spongy expansion of the fungus, the microcosmic version of the universe, to which it offered transcendent return. The symbol of the Raven was the chalice, which suggests that the Raven's bread was the fortifying agent in the sacramental potion, as in the wine of Maron, and the drink was metaphorically a cup of bull's blood. Sometimes the Raven is shown handing the drink to the two banqueters in a bullhorn *rhyton* vessel, reinforcing the metaphor. It also was supposedly skewered bits of the bull's roasted meat, although depictions show the Raven pecking at the meat, with the skewer held vertically above the clasped hands of the Father and his adoptive son, above the burning fire in the brazier, which would be quite unlikely in reality. However, the skewered meat presents a credible likeness to the mushroom for which it is the metaphor. Significantly, the sixth grade in the initiatory sequence was Perses, the Persian, who was the 'keeper of the fruits,' and his name suggests Perseus, who was the father of Perses, the etiological founder of the Persian people. The Mithraeum lodges were not banqueting clubs, nor are the tiny confined subterranean chambers appropriate venues for slaughtering a bull, disposing of the copious flood of its ensuing blood, roasting its butchered flesh, and serving an ordinary dinner. Other aspects of the ritual activity involved miming with animal masks, sexual humiliation, physical intimidation, and rowdy hazing, as is a common feature in initiatory admission to secret societies.

The tauroctony or 'bull slaughter' in Mithraism was a mythical event, often mistakenly equated to the *Taurobolium*, in which an actual bull was slaughtered on a grating above the initiate who was bathed in its blood. This was a rite in the religion of Cybele as imported into Rome in the third century BCE as the Great Phrygian Mother, in which the initiates represented Attis and practiced self-castration in their frenzied ecstasy. Attis was traditionally represented wearing the Phrygian cap and the frenzy of the rite may well have involved a similar fungal intoxicant. The remains of an ancient *Taurobolium* lie beneath the Vatican, but it was not the tauroctony of Zoroastrian Mithraism. Churches, however, were often also built above Mithraea, as in the Church of San Clemente, near the Roman Coliseum.

Soldiers of Christ

The Mithraea resemble drug dens, rather than banqueting chambers, sometimes with other rooms for rituals and indoctrination. Various psychoactive substances were probably involved in the successive grades of initiation, and the chamber was probably fumigated with incenses like cannabis, as seems to have the more ancient custom with the *haoma* cult indicated at archaeological sites, but the role of the *Amanita muscaria* as the bread served by the Raven in the religion explains to a large measure how the mushroom cult was promulgated throughout Europe as the supposed cohesive civilizing force until its official suppression by the Conversion. The third grade of Mithraism, however, was the Soldier, enlisted for the cosmic battle, and it seems likely that the concept of a brotherhood of warriors and its ritual indoctrination, like other aspects of Mithraism, was expropriated by Christianity, as was clearly the case with the sacrament of Confirmation, which made a Christian a soldier of Christ, instead of Mithras.

The *haoma* sacrament probably was transferred to groups like the Knights Templar and medieval knighthood. The ancient wolf sacrament continued, moreover, among the Nordic peoples and persisted in their berserker rites even after their conversion. It also continued in the Eastern Church among Gnostic sects like Manichaeism, whose Persian prophet Mani arouse in third-century Mesopotamia, incorporating dualistic Gnostic elements of Zoroastrian religion with Christianity, and which spread to southern Europe in the tenth century and persisted in China until the nineteenth, where they were noted for their ecstatic rituals and their fondness for red mushrooms. Where Mithraism in the Middle East persisted in fringe peoples only marginally assimilated into Islam, Mithras was still celebrated as late as the twentieth century with a sacrament of the *Amanita muscaria* (Ruck *et al.*, 2011). There were also numerous sects of early Christianity with a similar Gnostic dualism and a fungal sacrament which were suppressed as heresies even before the Conversion. In the mid first century, Paul reproached his congregation in Corinth for practicing the Eucharist in a manner that had caused the sickness and death of quite a few of their members (Ruck *et al.*, 2013; Ruck, 2015a). A fourth-century Christian sanctuary uncovered beneath the eleventh-century Basilica of Aquileia north of Venice preserves a mosaic floor ornamented with baskets of *Amanita*s and snails. The chamber was an early Christian meeting hall or agape and the floor decoration is plausibly interpreted as a depiction of the Eucharist (Fabbro, 1996). As recent as the end of the sixteenth century, an epistle of a monk on the Holy Mount of Athos details a miracle: that the Eucharist altar grew into the shape of 'a holy mushroom with its cap in the shape of forty apples which ascended over the holy table and overshadowed the entire sanctuary.' Those found infirm in the cloister who tasted of the holy mushroom were healed (Goldblatt, 1994).

The twelfth-century Basilica of San Vicente in Ávila replaced a nearby Mithraeum. It blatantly displays the mushroom as the food of the celestial banquet on the tympanum of its portal, with the portal itself, as always, indicating a distinctly fungal design, with the opening, either with or without a dividing mullein, suggesting the stipe supporting the hemisphere of the tympanum as its cap (Ruck, 2006). The tympanum itself is half of the almond-shape or *mandorla* that traditionally represents the vulva of the Goddess, assimilated into Christianity as the gateway to Paradise. Only the elite, who reserved for themselves the direct contact with deity, would recognize this fungal design as they passed through the portal to sacred space, but it surely was intentional, an indication of a heretical version of the Eucharist that perpetuated a sacred plant involved in the pagan cults that the Church Dominant had suppressed.

Old Europe

It was, moreover, only the urban centers under direct control of the bureaucracies and the Church that converted. The old religions continued in the countryside and villages (*pagus*), where the country folk or 'peasants' (*pagani*) preserved many aspects of pre-Christian tradition, called Paganism after them. The mushroom cult, in various forms, was one of these, not only as remnants of Mithraism, but also apparently because there were indigenous sources as well, predating the Roman Empire and dating back even to before the Indo-European migrations of the mid second millennium BCE. Shamanism involving mushrooms survived into the twentieth century in places like Lithuania and Iceland, the latter converting to Christianity only in the tenth century and then mainly to improve economic integration with the European mainland (Nichols, 2000). Rock art from the Neolithic (sixth millennium BCE) in Catalonian Spain at Selva Pasquale depicts mushrooms, probably *Psilocybe hispanica*, as dancing anthropomorphisms, with a fresco of a bull delineating in greater detail a natural likeness suggested by the stone surface (Akers *et al.*, 2011). It forms an element in a total rock configuration aligned and oriented as a solstitial marker and the site was clearly involved in sacral rites. Similar rock paintings in northern Africa, perhaps as old as the eighth millennium BCE depict shamans consubstantial with a fungal identity, as well zoomorphic transmogrification into an antlered deer and bees. Some depictions suggest consubstantial anthropomorphisms of *Amanita muscaria*. Rock art of the San people of South Africa, and elsewhere, also indicates probable psychoactive agents for accessing shamanic rapture. The similarity of metaphors with traditions from Classical antiquity and with those documented in the New World suggests that the spirit supposedly resident in the entheogen communicates with the shaman, as is commonly claimed.

Issenheim Altarpiece

Certain works of European art from the Renaissance suggest that a mushroom cult continued in elite societies of Christians. The most defining characteristic of the *Amanita muscaria* is the persistence of its potentiated toxin as a metabolite in urine, perhaps reflected in the ancient tradition of the second birth of Dionysus from the groin of his father. Between 1512 and 1516, Matthias Grünewald painted an altarpiece for the monastic hospital at Issenheim, in Alsace, now displayed in the Unterlinden Museum at Colmar (Ruck *et al.*, 2007). The monastery claimed Saint Anthony of Egypt as patron and it tended patients suffering from the affliction of ergotism named Saint Anthony's fire after the saint. Prominent in its complex of images presented in three layers of unfolding panels is the depiction of the divine Infant's *vase de nuit* or chamber pot, above which is a transparent crystal vessel of ornate Persian design like a monstrance containing the amber fluid of the Baby's urine, above which, the Virgin, in heaven amid a consort of angelic and demonic musicians appears, wearing a crown of flames surrounded by an orange nimbus, as she blesses the sacrament. The risen Christ is depicted in the adjacent panel to the right rising from the tomb, surrounded by the same nimbus, his white legs trailing the white burial shroud and presenting a credible anthropomorphism of the *Amanita muscaria*. At the innermost third level of presentation, which was visible only on the saint's day and for special rituals, two scenes with Saint Anthony, patron of mushrooms-seekers, flank a shrine with wood carvings. On the right, demons torment the saint. A poor deformed man, afflicted with the pustules of the disease, clutches a bible beside a tree trunk that is host for fungi. On the left, the saint is depicted entertaining a visit from the Hermit Paul of Thebes. For their meagre banquet, a Raven descends delivering two bits of Raven's bread, whereas ordinarily the saint was sustained by a single daily piece of the bread from the Raven. Beneath the Raven, a deer approaches, about to graze on some of the mushrooms for which the *Cervidae* are notably fond, including the *Amanita*'s metabolite in urine. Another deer rests between Anthony and Paul, engaged in conversation, probably on the subject of their miraculous nourishment in the desert. The motif of the deer hunt in medieval and Renaissance art probably always had the gathering of the mushroom as its referent. Both Saints Hubertus and Eustatius experienced a vision of the Christ suspended between the antlers of a stag while out on the hunt.

Bacchanal of the Andrians

Between the years 1523 and 1526, while in residence with the Duke, Titian painted *The Bacchanal of the Andrians* for Alfonso I d'Este to decorate the antechamber to the bedroom he shared with his second wife, Lucrezia Borgia, daughter of Pope Alexander VI (Heinrich, 1995; Ruck *et al*., 2007; Ruck *et al*., 2012). The theme of the antechamber's art was depictions of ancient orgies or revels. The painting is now in the Museum of the Prado in Madrid. There are two levels of reality in the depicted scene, the islanders of the Greek isle of Andros, who held an annual revel to celebrate the arrival of the god Dionysus, at which time the rivers of the island flowed with wine. The other level of reality is the materialization of the god's nude male attendants, scooping up the wine from the river, drinking it, and carting it away. Shockingly nude in the corner of the right foreground reclines a voluptuous female, who is Ariadne, the bride of the god, exposing her genital area. Lucretia may has served as model for Ariadne. Beside her is the god, Dionysus-Bacchus, but incongruously as a child, lifting his shirt to urinate in the river's stream, his penis and her vulva adjacent. The two levels of reality appear unaware of the other's presence, except for two figures. One from the mythical entourage is pouring the liquid from a pitcher into the uplifted saucer held by a woman, unaware of him behind her, as she reclines on the bank of the stream, totally engrossed in conversation with her neighbor. Beside her another from the mythical entourage is looking at a crystal pitcher held aloft by an islander in a group of Andrians dancing about a tree, in whose branches sits a large peacock, emblematic of the changes of color effected through alchemical transmutation, thus identifying the urine from the river's stream as the golden elixir of immortality. The two crystal pitchers mark the nexus where one reality impinges on the other, suggesting that the liquid content is visionary or hallucinatory.

In front of the women in conversation by the riverbank is a piece of musical notation; the music is a perpetual canon or round whose text reads, "He who drinks but once and doesn't drink it again knows not true drinking." The reference is clearly to the child's pee, round and round, which is being poured into her cup and which appears again in the monstrance of the crystal pitcher. Another of the males from the mythical entourage behind the two conversing women is looking directly at the peeing child and knows full well that it is divine urine that he is scooping from the stream. The source of the river appears personified as a river god in the distant right above the reclining Ariadne. He is a white-bearded man, apparently passed out, the river's fountain issuing from between the legs of his nude body, ostensibly from his genitals as urine. Equally unconscious and in the same pose is the nude Ariadne, he and she probably adding to the urine flowing in the stream. Beside the peeing god is an overturned large stemmed golden chalice, of probably ecclesiastical design, suggesting that the alchemical elixir of transmuted pee is the Eucharist.

The peeing homunculus or little man was a motif in alchemical depictions, releasing his urine within the alembic containing the potion of transcendence, and the alchemists riddled that the so-called stone that conferred the knowledge of philosophers was actually something despicable, common and everyday, tossed out as offal into the streets. Since both Grünewald and Titian were in residence for an extended period as they accomplished their patrons' commission, it is difficult to imagine that the artists had not partaken of the sacrament encoded in their paintings.

Ghent Altarpiece

In 1432, Jan van Eyck completed the Ghent Altarpiece (titled the *Adoration of the Mystic Lamb*) that his brother Hubert had begun but left unfinished upon his death in 1426 as a commission from Duke Philip the Good of Burgundy, to coincide with the birth of the Duke's son from his third wife Isabella of Portugal and the inauguration of the warrior brotherhood of knights called the Order of the Golden Fleece (Ruck and Hoffman, 2012). The Duke was a great enthusiast of alchemy. Here in the outer level of the polyptych altarpiece, the urine appears in a transparent flask catching the light of the sun on a window ledge of the bedchamber where the Virgin, already pregnant, is receiving the news of the Annunciation. The dove of the Annunciation descending above her head was the traditional Flemish design for the ciborium containing the bread of the Eucharist, and the central panel of this outer level of presentation depicts the sacristy chamber where the priest prepared to administer the Communion.

The flask of urine is proof that the Virgin is indeed pregnant. Ancient and medieval doctors studied the effluents of the body as a clue to the inner workings of the patient's physical condition, and the urine as the most copious was of particular significance. Some doctors, called 'piss prophets,' claimed that they could determine pregnancy from the color of the urine, and there are published color charts that they employed as a guide. The flask of urine was also a metaphor elaborated by Saint Bernard and others to explain how the Virgin could conceive and yet remain *virgo intacta*, with unbroken hymen. It was like a beam of sunlight penetrating the glass of a flask, imparting its color to the liquid, but leaving the vessel intact.

The Altarpiece originally was fitted with a mechanism of clockwork that daily opened the panels of the outer presentation, accompanied with mechanical music, to reveal the inner presentation for the Eucharist. Here the same model who served for the pregnant Virgin is portrayed on the right upper panel as the shockingly nude Eve, already pregnant, and also in the central panel as the Virgin now elevated to her role as the *Regina Coeli*, Queen of Heaven. She is enthroned beside Jesus, now her consort as the Almighty. He is an astonishingly handsome young man, and he is also the same model who served for the portrayal in the upper left panel opposite Eve for the portrait of the equally shockingly nude Adam, about to walk out of his niche to assume his future role as mate of Eve's redemption in the persona of the *Regina Coeli*.

The divine couple sit enthroned beside the Baptist, the original patron of the Church, to witness in the scene below them the marriage feast of the Mystic Lamb. The scene is the Apocalyptic Revelation of John of the stream flowing through the New Jerusalem, when he rescinds the prohibition of the Garden of Eden and invites all to eat freely now of the forbidden fruit of the knowledge of good and evil that will make man like onto God and his angels. The Lamb stands upon an altar in a flowering meadow, surrounded by the *Arma Christi*, the instruments of the Crucifixion. The Lamb's Blood spurts from His body, as the source for an elaborate fountain that is the source of the river. The basin of the fountain contains gemstones and coral. Water passing over magical stones was thought to absorb their potency. The coral was supposedly derived from the blood that dripped from the decapitated Gorgon Medusa, from which sprouted spongy mushrooms that only turned Petrified as coral when immersed in water. In scientific nomenclature coral belongs to the family of the *Gorgonacea* and its name as 'coral' derives from ancient Greek, where it is the diminutive for the *kore* or pubescent girl, probably linking the blood to the menses. The esteem for coral is of the greatest antiquity, traceable back to the Zoroastrian Magi and the Vedic Brahman priests, who endowed it with sacred properties, probably since it was metaphoric for the *haoma* and Soma sacrament. As Petrified, it was the original for the alchemical *lapis philosophorum* or 'stone of the philosophers.' In medieval symbolism, it was known as the *lapis Christi*, the Petrified Blood of Christ.

To the left of the central panel of the Mystic Lamb, the Duke is portrayed amid a troupe of knights as the Soldiers of Christ, approaching the sacred meadow of the fountain river, about to lay claim to sovereignty over the New Jerusalem. Their path is strewn with gemstones and corals. The matching panel opposite on the left depicts Saint Anthony and the Hermit Paul, probably still discussing the miracle of the Raven's bread, as they, too, approach the Mystic Lamb. Anthony carries a rosary of coral beads, and several gemstones lie in his path at the base of the tau-cross he carries as a walking stick, prodding the ground as a mushroom-seeker looking for truffles, which folkloric tradition ever since antiquity considered the Petrified urine of a stag. Anthony was also the patron of pigs, which were employed for scenting out the presence of the underground mushrooms. The sows are drawn to them by the noticeable scent of male urine, androstenol, which the truffles produce. Customarily they are hunted *avec la mouche*, 'with the fly,' as is the phrase, because like the *Amanita muscaria* they attract swarms of flies. Islamic tradition, allegedly going back to Muhammad, claimed that the truffle had an effect on the eyes, which implies alteration of vision.

On the outer presentation, the Baptist is depicted in grisaille as a statue holding the cup of poison to which he was immune, its toxicity indicated by the serpent lifting its head from the vessel. In the inner presentation, the spigot on the fountain is a grotesquerie that is the face of the serpent in the cup of poison. An inscription on the rim of the fountain identifies its water as *Aqua Vitae*, the 'water of life,' which by this date had been already for about a hundred years been labeled as the alchemical distillate.

The Altarpiece identifies the blood of the Lamb pouring over the corals and gemstones as the blood that flowed from the side of Christ, when pierced with the lance of the Roman centurion Longinus, which is depicted among the instruments of the Crucifixion. The Duke actually had a phial of the Petrified Holy Blood, enclosed and sealed within a crystal tube, that was given to his ancestor Sybilla of Anjou on Christmas of 1148 in Jerusalem, a holy relic allegedly discovered by the Knights Templar, and when she touched it she had a vision of the New Jerusalem, which was going to be the city of Bruges in Flanders. It is preserved in Bourg Square in the city of Bruges, and every Friday up until 1325, and then intermittently thereafter, many witnesses claimed that the dried blood liquefied, sometimes dripping as newly shed blood from the reliquary. By this tradition, the story of the Altarpiece reaches back to Philip's twelfth-century ancestor, Philip of Alsace, the Count of Flanders, and the tale of the Grail commissioned from the poet Chrétien de Troyes.

The Garden of Eden

Wasson continued to suspect that confirmation of his identification of Soma would be found in Christianity. When it came in the form of John Allegro's *Sacred Mushroom and the Cross* (1970), he didn't recognize it, much to Allegro's disappointment. As an amateur scholar, Wasson customarily deferred to the opinion of professional authorities. Allegro, the linguist and scholar of the Dead Sea Scrolls, an academic with impeccable credentials in ancient Classical and Near and Middle Eastern languages, had already published several books; he had read Wasson's writings and appropriately acknowledged them, knew of his Mexican discoveries, and accepted his identification of Soma as the fly-agaric. Wasson, like all Allegro's critics, would have found the linguistic documentation beyond his expertise. He asked a rabbi and a Catholic Monseigneur in his acquaintance their opinion and they assured him that there wasn't a word of truth in it.

The Wondrous Mushroom: Mycolatry in Mesoamerica was the last book that Wasson saw through to publication (Wasson, 1980). By this time, he had become quite convinced that the experience that had occurred with María Sabina was religious in essence. His later work with the Anishinaabeg (Ojibwe) shaman Keewaydinoquay (Peschel) demonstrated how widespread or universal was the role of sacred visionary substances in the origin and practice of religion (Keewaydinoquay, 1984), requiring a new designation devoid of the cultural environment of the psychedelic era. For this, he endorsed entheogen: "'God within us,' those plant substances that, when ingested, give one a divine experience. The new word notably captures the rich cultural resonances evoked by the substances, many of them fungal, over vast areas of the world in proto- and prehistory."

In *Persephone*'s *Quest*, Wasson's final book, published just after his death in 1986, he proclaimed by its subtitle that he had concluded that entheogens were the origin of religion (Wasson *et al.*, 1986). The first chapter was Wasson's final summation. "As I am nearing the end of my days," he began, "I will draw up an account of our mushroom quest." Here he came back to the question of a mushroom cult in Christianity. "I once said that there was no mushroom in the Bible," he wrote. "I was wrong.... I hold that the fruit of the Tree of Knowledge of Good and Evil was Soma, was the *kakuljá*, was *Amanita muscaria*, was the Nameless Mushroom of the English-speaking people."

Abstract

This paper describes the traditional mycological knowledge of the Nahua of San Isidro Buensuceso, on the slopes of La Malinche Volcano National Park, in the state of Tlaxcala, México. The results described in this paper were obtained through interviews with villagers selected at random; a freelisting technique was used to determine the cultural significance of the mushrooms of the region. A total of 48 species, which had 65 Náhuatl names and 40 in Spanish, were identified. Although San Isidro villagers consider mushrooms to be a natural resource mainly used for food, they also use them for medicine, insecticides and trade. This paper presents traditional information on the morphology, ecology, fenology and consistency of the mushrooms found around San Isidro. It proposes that, from a cultural perspective, *Gomphus flocossus*, *Ramaria* spp. and *Boletus* spp. are the most important species of the region.

Keywords: Ethnomycology, La Malinche National Park, Nahua, traditional uses of fungi, wild mushrooms

Introduction

The Nahua are the most numerous and widely distributed ethnic group in central México. Nevertheless, few academic studies have focused on describing the group's traditional knowledge of mushrooms. Nahua used fungi during rituals, according to historic record. Nahua prehispanic poetry describes fungi consumption in religious ceremonies. The fungi used in those ceremonies commonly were known as "xochinancatl" or "*teonanácatl*" (Wasson 1983). *Psilocybe aztecorum* Heim, known as "niños," "niñitos" or, in Náhuatl, "apipiltzin," currently is used in religious rites in San Pedro Nexapa, on Volcan Popocátepetl. *Psilocybe muliercula* Sing. & Smith is a hallucinogenic mushroom used by the Nahua in Tenango del Valle, in the state of México (Guzmán 1983).

Although it is not known whether Nahua ceremonial use has endured elsewhere, other uses and aspects of the traditional knowledge have been studied. Dubovoy (1968) analyzed various indigenous codices and presented evidence that, in the past, the Nahua used mushrooms for food. Martín del Campo (1968) translated Náhuatl mushroom names registered by Herrera and Guzmán (1961), explained their meaning and offered synonyms and ecological information. Guzmán *et al*. (1975) studied a specimen of *Ganoderma lobatum* (Schw.) Atk., which is displayed in a place of honor in a church in Chignahuapan, Puebla. Local people revere this particular mushroom, which was found in a local forest, believing that it has miraculous properties because of designs on its surface that suggest the face of Christ, the sun, the moon and the number 80. De Ávila *et al*. (1980) analyzed the traditional Náhuatl nomenclature that residents of Hueyapan, Morelos, used for mushrooms, documenting how the mushrooms were used and how they were prepared for consumption. González (1982) carried out a study in Santa Catarina del Monte, Texcoco, obtaining information on the Náhuatl nomenclature of the local mushrooms, where they grew and how they were used. Martínez-Alfaro *et al*. (1983) investigated the importance of mushrooms and the differences in the traditional knowledge of some communities in Puebla, gathering information on the origin of the mushrooms, their Náhuatl names, uses and importance. That paper concluded that the perception of mushrooms varies according to the viewer's age, sex, economic position and degree of cultural integration into the community. Gispert *et al*. (1984) interviewed people of all ages in two Nahua communities in the state of México. They asked their subjects nine questions dealing with mushroom nomenclature, classification, morphology, ecology and use. They also collected 24 mushroom species. They concluded that, in the village of Parres, mushroom trade is an important activity while, in the village of El Capulín, mushrooms are used only for home consumption.

In Tlaxcala, there is no documentaton on the current use of mushrooms by the Nahua, although there is some evidence that the ancient Nahua knew of their hallucinogenic and edible properties (Wasson 1983). The oldest reference is found in a paragraph in the book *Relación de Tlaxcala* (*Tlaxcala Connection*), written by Muñoz-Camargo (1586). This paragraph describes the use of a mushroom called "nanacatl", which the local aristocracy ate to predict the future. When these seers ate the mushroom, they were said to become drowsy, faint and have visions. Rojas-Garcidueñas (1935 in Wasson 1983) published an anthology of plays written toward the end of the 16th century, called *El Teatro de la Nueva España* (*The Theater of New Spain*). One of the plays (it is not known whether it ever was performed in public) included in this work shows the opposition of the church to the use of hallucinogens. The play describes a baptism ceremony in which royalty ate such mushrooms. Wasson (1983) interpreted the words "hongol," "demon" and "idol" in this play to mean "teonaanacatl" or "xochinanacatl" because of the way the word "mushroom" is translated into Spanish.

No one has determined the taxonomic identity of the mushrooms used for religious purposes by the ancient Tlaxcaltecan. However, such a register might include *Psilocybe aztecorum* or *Copelandia cyanescens*, two species with hallucinogenic properties that have been found in Tlaxcala (Guzmán 1983, Santiago-Martínez *et al*. 1990). Additional historical references to these mushrooms can be found in ancient writings. One example is the name Antonio Xochinanácatl ("xochinanácatl = hongo flor = mushroom flower"), which appeared in a judicial proceeding in Tlaxcala long ago. The word "Nanacamilpa" means "milpa de hongos" ("nanacatl = hongo y milpa = mushroom and cornfield") and is the name of a Tlaxcaltecan municipality founded in 1858. It is not known why this municipality was thus named (Wasson 1983). Residents of some communities on the slopes of Volcan La Malinche, Tlaxcala, still speak Náhuatl, with the village of San Isidro Buensuceso having the greatest number of inhabitants who speak it (79% of the population; INEGI 2000).

No studies have been conducted to measure the cultural significance of fungi, other than investigations into the roles fungi have played in the lives of Mesoamericans since pre-Hispanic days. For this reason this study was launched to describe the traditional mushroom knowledge of the people of San Isidro Buensuceso, including information on mushroom nomenclature, morphology, use and when and where mushrooms grow. The number of times mushroom names were mentioned in a free listing was used as an indicator of the cultural significance of those mushrooms to San Isidro residents. We do not know which factors they rely on when assessing the cultural importance of mushrooms; natural availability (abundance in the forest) and income derived sales could be two such factors. To test whether this is so, data from an ecological study were used to determine the relationship of the abundance of various mushrooms species in the forest and the cultural significance of such mushrooms to the community. Cultural significance also was compared to the price of each species.

Materials and methods

Field of study

The village of San Isidro Buensuceso, which lies on the southern slope of Volcan La Malinche, at 2600 m (FIG. 1), belongs to the municipality of San Pablo del Monte, in the southeastern part of the state of Tlaxcala. The community was founded near the end of the 19th century and has 6253 inhabitants (INEGI 2000). It has a temperate, subtropical climate, with plenty of summer rain and with average winter rain of less than 5 mm a month. The annual temperature varies between 12 C and 18 C. March, June, July and August are the warmest months, with temperatures between 14 C and 15 C, while the coldest months are December, January and February, with temperatures between 11 C and 12 C (Garcia 1986).

The residents of San Isidro Buensuceso collect mushrooms in local forests, as well as in areas surrounding the town and in cultivated fields. The vegetation of the forests includes: *Abies religiosa* (HBK.) Chamb. & Schl., *Pinus hartwegii* Lindl. and *Pinus montezumae* Lamb. Some forest patches with steep slopes, and a few areas near the crater Hueytlaocan have a mixture of *Alnus jorullensis* H.B. & K., *Salix* spp., *Cupressus* sp., *Quercus* spp. and *Abies religiosa*. The main types of shrubbery include secondary elements such as *Baccharis conferta* HBK. and *Senecio* spp. Grasslands have filled in the open areas; they consist of *Muhlenbergia macroura* (H.B.K.) Hitch., *Stipa ichu* (Ruiz & Pavón) Kunth. and *Eragostris bartieri* Dar.

Fieldwork involved 26 visits to San Isidro Buensuceso, in which 226 semistructured interviews were conducted. For these interviews, participants of both sexes and of different ages (5-90 yr) were selected randomly following Bernard (1988). The random selection was done as follows: 100 numbered dots were placed around the edge of a local map. Pairs of numbers were chosen randomly from a plastic bag, and lines were drawn between those numbers on the map. After 50 lines were drawn, the sampling was begun. The uneven areas created by the lines were numbered, and some of those plots were chosen randomly until 22 had been selected. Ten or 11 households in the designated area were visited, again at random.

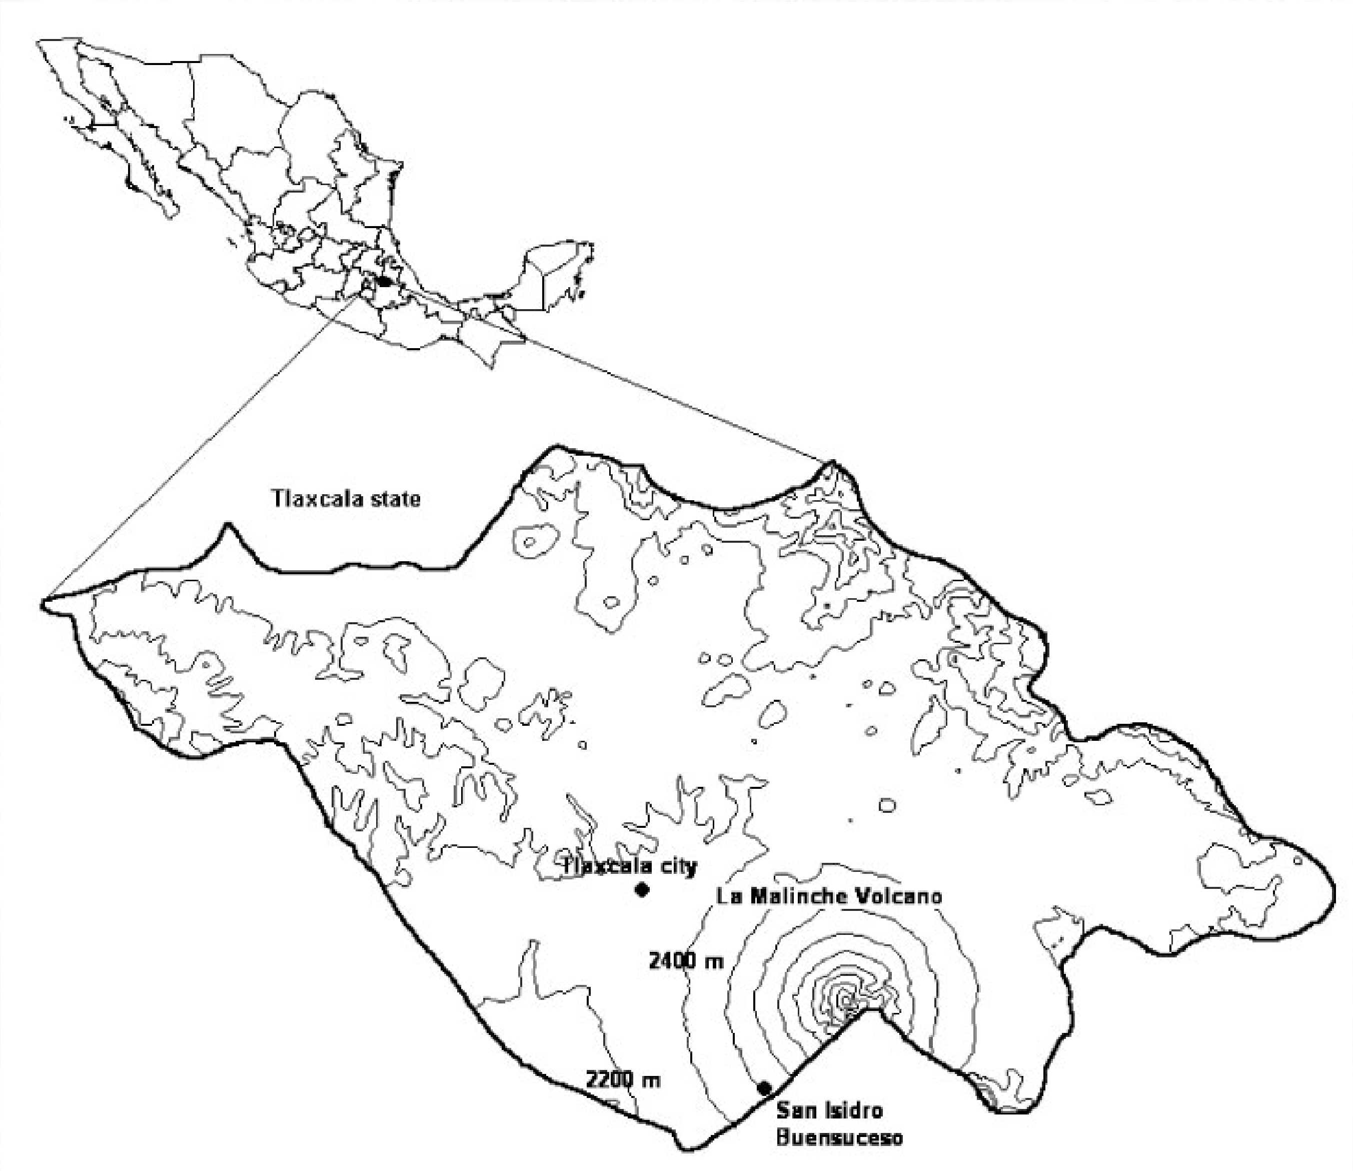

Fig. 1. Location of San Isidro Buensuceso and Malinche National Park.

In each interview, direct questions were used and, on several occasions, fresh or dry mushrooms and field guides were shown as stimuli. The interviews covered these aspects: common names of mushrooms, ideas about the origin of mushrooms, elements required for their development, classification according to the "cold-hot" system (described later), words used to name the different parts of the mushrooms, mushroom uses, methods of cooking, criteria used to distinguish edible from poisonous mushrooms, the months mushrooms are found, the locations where they are found and the prices at which they are sold in the community.

During the rainy seasons of 1998-2000, fieldtrips were undertaken with key informants from the village, with the intention of collecting the mushrooms known and used by the locals and to corroborate the information obtained about times and places of growth. All mushroom species were collected in La Malinche National Park. The collections were taken to the Centro de Investigaciones en Ciencias Biologicas of the Universidad Autonoma de Tlaxcala (UAT) (Research Center of Biological Sciences) with the aim of identifying and drying them, as suggested by Cifuentes *et al*. (1986). Different taxonomic keys were used to identify mushrooms, depending on the genus involved; those keys were supplied mainly by Abott and Currah (1988), Bon (1987), Jenkins (1986), Moser (1983), Romagnesi (1967) and Singer (1975). The specimens then were deposited in TLXM (Holmgren and Holmgren 1995). The initials used for collectors are: AK (Alejandro Kong), E-T (A. Estrada-Torres), OHT (O. Hernández-Totomoch) and AM (A. Montoya). The classification used was based on that proposed by Hawksworth *et al*. (1995). Náhuatl names were written as pronounced by the San Isidro villagers and later translated into Spanish, using the Simeon (1977) and Sullivan (1992) dictionaries. The names then were compared with the information published by De Ávila *et al*. (1980).

To determine the cultural significance of the mushrooms studied, structured interviews were conducted with 46 participants (24 females and 22 males, most of them married couples). One of the households of each area previously selected in the semistructured interviews was chosen for this purpose. Structured interviews made use of free listings, in which respondents were asked to name 20 mushrooms that they were familiar with (the question in Náhuatl was: ("rnechunili tlanitoca nanacatl" = "Tell me the names of 20 mushrooms you know") (Weller and Romney 1988, Bernard 1988). Each interview was carried out independently of the others. The surveys were conducted during the dry season (January-April), ensuring that all mushroom species had the same probability of being mentioned.

TABLE I. Mushroom species and traditional names used in San Isidro Buensuceso

Scientific name and voucher specimens	Náhuatl name	Spanish name
1. *Agaricus campestris* L. *AM 1644*	*ayotzin*, *ayutzin* (*ayotl* or *ayutl* = turtle; ayohtli = pumpkin; *tzin* = diminutive reverential; little turtle or little pumpkin)	Champiñón
2. *Amanita caesarea* (Scop.) Pers. *AM 1598*	*ayoxóchitl* (*ayotl* = zucchini; *xochitl* = blossoms; zucchini blossom mushroom) *cuazitlal* = ? *aquiyoxóchitl* (*quiyotl* or *quiotl* = vástago o retoño; *xochitl* = flower).	flor de calabaza = zucchini blossoms amarillos = yellow mushrooms
3. *Amanita tuza* Guzmán *AM 1747*	*cuatlamanil, cuatlal* (*quaitl* = head; *tlamanil* = ?) *iztacnanácatl* (*iztac* = white; *nanacatl* = mushroom; white mushroom)	-
4. *Armillaria mellea* (Vahl) P. Kumm. *AM 1742*	*tetecuitl* (*tecuitlatl* = slime or *cuitla*, excrement; probably means stone excrement) *xotlalist* = ? *xocuitlas* = ?	-
5. *Boletus atkinsonii* Peck *AM 1595*	*xotoma, xotomame, xotomate, xotomatzi* (icxi = paw, *tomahuac* = fat, fat paw mushroom; or *xitomatl* = red tomato, mushroom like tomato) *tlapalxotoma* (*tlapalli* = color), *tlatlauxotoma* = ? *tlacuaxotoma* = ? *pantenanácatl* (pan = bread; mushroom like bread) *tlaxcaxotoma* (tlaxcalli = tortilla; tortilla mushroom) *zacaxotoma* (*zacatl* = grass) *ocoxaltoma* (*ocoxal* = pine cone litter) *oyamelxotoma* (*oyametl* = fir)	panza grande = big belly pante = ? cemita = meat sandwich pata gorda = fat paw
6. *Boletus pinophilus* Pilát & Dermek *OHT 05,22*	*xotoma, xotomame, xotomate, xotomatz xitomatl* = looks like red tomato, mushroom like tomato; *tlapalxotoma, tlatlauxotoma, tlacuaxotoma, pantenanácatl, tlaxcaxotoma, zacaxotoma, ocoxaltoma, oyamelxotoma* See *B. atkinsonii*	panza grande = big belly pante = ? cemita = meat sandwich pata gorda = fat paw
7. *Cantharellus cibarius* Fr. *OHT 25*	tecosa, tecusa, tecutzal (*cuztic* = yellow; there is a yellow wild flower called *teguza*)	amarillitos = little yellow mushrooms
8. *Chroogomphus jamaicensis* (Murrill) O.K. Mill. *OHT 21*	*tlapaltecosa tlapaltecosauitl* (*tlapalli* = color or painting; it refers to a purple *tecosa*) *xilpatzutl* = ?	hongo morado = purple mushroom
9. *Clitocybe giba* (Pers.) P. Kumm. *OHT 44*	*izquilo* (*izquitl* = perfumed flower; the name refers to the mushroom's sweet smell) *totomoch* (*totomachtle* = the corn husk; its color resembles the color of cornhusks)	hongo de campana = bell mushroom campanilla = little bell
10. *Clitocybe* cf. *squamulosa* (Pers.) Fr. *OHT 24*	*izquilo, totomoch* See *C. gibba*	hongo de campana = bell mushroom campanilla = little bell

11. *Gomphus floccosus* (Schwein.) Singer *AM 1609*	*tlapitzal* (*tlapitzalli* = trumpet; mushroom with the trumpet shape) *oyamelnanácatl* (*oyametl* = fir; *nanacatl* = mushroom; fir mushroom)	corneta = trumpet cornetilla = little trumpet
12. *Hebeloma* cf. *mesophaeum* Fr. *AM 1713*	*ocoxalnanácatl* (*ocoxalli* = pine cone litter, it refers to pine needles; mushroom which grow in pine needles) *rastrojonanácatl* (rastrojo in Spanish means stubble; it refers to a mushroom growing in pine cone litter which looks like stubble)	hongo de ocote = pine cone mushroom
13. *Helvella crispa* (Scop.) Fr. *OHT 19*; *AM 1602*	*pantalonanácatl* (pantalón in Spanish means trousers, *nanácatl* = mushroom) *huihuixocatzi* (*uiuixqui* = weak; *xocatzi;* = ?, weak mushroom ?) *gachupitzetze* = ? *soldadosnanácatl* (*soldados* in Spanish means soldiers, the soldiers mushroom) *huevisnanácatl* (huevo in Spanish means egg; egg mushroom)	*gachupi* blanco (blanco = white, *gachupi* = colloquial Mexican Spanish for Spaniards) orejas = ears güerito = little blond mushroom orejas de ratón = mouse ears
14. *Helvella lacunosa* Afzel. *OHT 20, 38*	*charronanácatl* (charro in Spanish means horseman; horseman mushroom) *cuatlil* (*quaitl* = head; *tlilli* = black; black head)	tamborcito = little drum negrito = little black mushroom *gachupi negro* = black gachupi
15. *Hygrophorus chrysodon* (Bastch.) Fr. *AK 2831*	*xilonananácatl* (*xilotl* = corncob; *nanacatl* = mushroom) *xilonaltzitzi* (*tzitzi* = ?) *xixilonanácatl*	señoritas = young ladies blanquitos = little white mushrooms
16. *Lactarius indigo* (Schwein.) Fr. *OHT 32*	*cacaxnanácatl* (*cacaxtli* = it refers a kind of bird and its blue color)	hongo azul = blue mushroom
17. *Lactarius salmonicolor* R. Heim *et* Leclair *OHT 30*	*chilnanácatl* (*chilli* = chilipepper; *nanácatl* = mushroom; referring to its bright red color or to the peppery flavor some informants claimed it has) *chilabuelita* (abuelita in Spanish means grandma), *chimelnanácatl, chilnanatzi, chichilnácatl, oyamelchilnanácatl*	cajetitos rojos = red cajetitos (something shaped like a dish), trompa de cochino = pig
18. *Laccaria bicolor* (Maire) Orton *OHT 18*	*xocoyoli, xuxocoyoli, xoxocoyoli, xoxocoyolnanácatl, xocoyolnanácatl* (*xogoyolli* = the last child in the family, *xogoyolti* is the plural form, *xocoyoles* the Spanishized plural. The name is given because it is one of the smallest edible mushrooms)	clavito = little nail
19. *Lycoperdon perlatum* Pers. *AM 1615*, *OHT 14*	*xiteburo, xitenanácatl, xitetl* (*xiuitl* = red herb; *tetl* = egg; *buro* = simplification of the Spanish word, *burro* = donkey; donkey egg mushroom) *cefamil* = ?	huevitos = little eggs
20. *Lycoperdon* sp. *AM 1605*	*xiteburo, xitenanácatl, xitetl cefamil* See *L. perlatum*	huevitos = little eggs
21. *Lyophyllum decastes* (Fr.) Singer *AM 1741*	*xoletl, xuletl (xoletl* = It must be very delicate, *xolectle* is one easily hurt, *xoleme* is the plural) *tlacualxoletl*, (*tlacuahuac* = oak) *ocolxoletl* (*ocotl* = conepines) *cuaxuaxoletl* = ?	clavitos = little nails hongo de mata = tuft mushroom
22. *Morchella elata* Fr. *OHT 31*	*olonanácatl* (*olotl* = corncob, they are like corncobs. The name applies to various species of *Morchella*)	olotes = corncobs
23. *Morchella esculenta* (L.) Pers. *AM 857*	*olonanácatl* See *M. elata.*	olotes = corncobs
24. *Pleurotus opuntiae* (Durieu & Lév.) Sacc. *AM 974*	*menanácatl* (*metl* = maguey, *nanácatl* = mushroom) *mesonanácatl* (megotl = dry maguey, mushroom of dry maguey) *huexonanácatl* (*huexotl* = willow, willow mushroom)	hongo de maguey = maguey mushroom
25. *Ramaria bonii* Estrada *AM 1599*	*xelhuas* (*xelguaztle* = brush or broom, mushroom broom)	escobeta = broom
26. *Ramaria cystidiophora* (Kauffman) Corner *AM 1715D*	*xelhuas* (See *R. bonii*)	escobeta = broom

27. *Ramaria rubripermanens* Marr & D.E. Stuntz *AM 1715C, 1747A*	*xelhuas* (See *R. bonii*) *cuamanox* = ? *xelhuastzitzi* (tzitzi = ?)	escobeta morada = purple broom
28. *Ramaria sanguinea* (Pers.) Quél. *AM 1747B*	*xelhuas* (See *R. bonii*)	escobeta = broom
29. *Ramaria versatilis* Quél. *AM 1766*	*xelhuas* (See *R. bonii*)	escobeta = broom
30. *Russula delica* Fr. *OHT 15*	*cuatecax* (*cuatlil* = head, *tecaxitl* = stone dish; mushroom with a cap like a stone dish, because it has the shape of the stone dish, or metate used to mash vegetables to make sauces) *cualtzitzi* (*cuatlil* = head, *tzitzi* = ?) *iztacnanácatl* (*iztac* = white, *nanácatl* = mushroom)	charritos = little horsemen tecajete = Spanicized word from *tecaxitl*
31. *Suillus pseudobrevipes* A.H. Smith et Thiers *AM 1596*	*poposo, pupuso* (*poposonallot* = foam; foam mushroom. Referring to the hymenium appearance)	panza = belly pancita chica = little belly
32. *Ustilago maydis* (DC.) Corda *AM 973*	*cuitlacoche* (*cuitla* = excrement; *cochi* = the pig; pig's excrement)	hongo de maíz = corn mushroom cochinito = little pig

Free-listing compilations leads to several conclusions. First, some items on the list are better known, more important or more familiar to respondents than other items. Such items usually are placed high on an individual list. Second, there is usually a wide range in terms of where residents will place each item in their lists. The free-listing technique, therefore, lets us find the most important items with minimal effort. The list will not be definitive. However, as the number of respondents increases, the list will becomes more stable and the order of items will tend not to change even when a few new items are added by new respondents (Weller and Romney 1988). This approach suggests that the names of the mushrooms referred to most often by respondents are those that have the greatest cultural importance in the community studied.

The hypothesis of this paper is that the importance of a mushroom species bears a relationship to its abundance in the forest and/or to its price. To prove this, a three-year ecological study was undertaken in an area of 1600 m2 in a nearby forest. Fruiting bodies of edible fungi were collected from four *Abies religiosa-Pinus* and four *Pinus-Alnus* transect lines along an altitude gradient in La Malinche National Park. In this area, it was possible to determine how many mushrooms grew in each of four sectors located at the same altitude as the village collection zones. Mushroom abundance was calculated by counting the fruit bodies of each species found in the area under study. The details of the methodology and the results of that ecological study will be published in a subsequent paper. A Spearman index was calculated with a statistics program (StatSoft Inc. 1995) to determine the correlation between frequency of mention and mushroom abundance or frequency of mention and prices.

Results

In total, 48 species were identified, which had 105 common names (65 Náhuatl and 40 Spanish) (TABLES I and II). The mushrooms identified were classified as Ascomycetes or Basidiomycetes. Among the first group, there were three main families: Helvellaceae, with two species; Hypocreaceae, with one species; and Morchellaceae, with two species. The second group contained: Russulaceae and Ramariaceae, with nine species; Boletaceae, with six; Tricholomataceae, with five; Amanitaceae, with four; Lycoperdaceae, with two; and Agaricaceae, Chantharellaceae, Cortinariaceae, Gomphaceae, Gomphidiaceae, Hygrophoraceae, Pleurotaceae, Strobylomycetaceae, Ustilaginaceae and Xerocomaceae with one species each.

Collection of mushrooms

Those who spend their time gathering and selling mushrooms are known as "hongeros", i.e., "mushroomers" or "those who gather mushrooms." Gatherers walk 10 km or more, spending 8-10 h in the process. Usually, at least two people, often of the same family or close neighbors, work together. Both men and women gather mushrooms, with the only difference being that men go farther afield. For example, the men search distant canyons to find bigger and better mushrooms. On occasion, they investigate almost inaccessible locations to find more mushrooms. The men return and give the mushrooms to the women, who have been collecting in the more accessible places. Women then take charge of all mushrooms and carry them back to the village.

TABLE II. Species and traditional names used to describe poisonous fungi

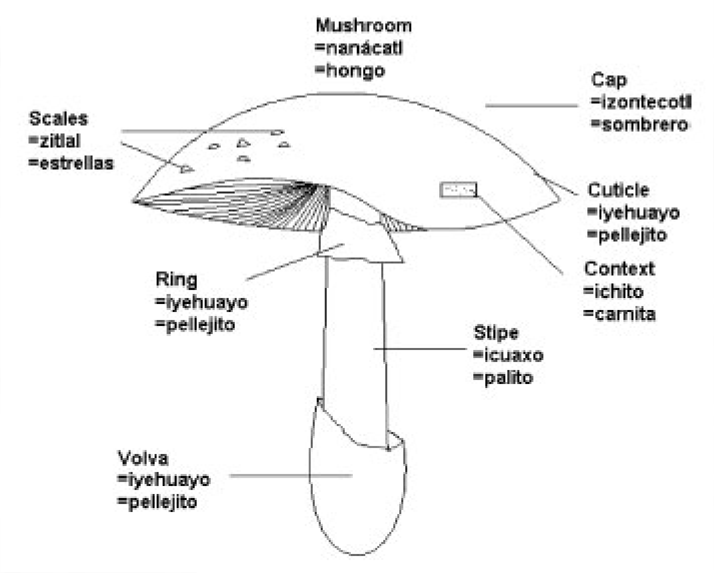
Scientific name and voucher specimens	Náhuatl name	Spanish name
1. *Amanita muscaria* (L.) Hook. *OHT 13*	*pizutnanácatl* (*pitzotl* = pig, *nanácatl* = mushroom; mushroom of the pig, referring to the bad mushroom) *zitlalnanácatl* (*zitlalli* or *citlalin* = star; mushroom of the star, referring to the scales, because they looks like stars)	hongo malo o venenoso
2. *Amanita* cf. *smithiana* Bas *AM 1594*	*pizutnanácatl* (See *A. muscaria*)	hongo malo
3. *Boletus miniatopallescens* A. H. Sm. & Hesler *AM 1607*	*xotomarabia* (*xitomatl* = looks like red tomato, mushroom like tomato; *rabia* = rabies, means that the mushroom is poisonous)	hongo malo
4. *Chalciporus piperatus* (Bull.) Bataille *OHT 04*	*poposorabia, poposo, pupuso* (*poposonallot* = foam, poisonous foam mushroom, referring to the hymenium appearance)	hongo malo
5. *Lactarius chelidoniun* var. *quelidonioides* (A. H. Sm.) Hesler & A. H. Sm. *OHT 11*	*pizutnanácatl* (See *A. muscaria*)	hongo malo
6. *Lactarius luculentus* Burl. *OHT 09*	*pizutnanácatl* (See *A. muscaria*)	hongo malo
7. *Lactarius mexicanus* Kong & Estrada *OHT 07*	*pizutnanácatl* (See *A. muscaria*) *cuatecax* de veneno (*cuatlil* = head; *tecaxitl* = dish stone; poisonous mushroom with a head like a stone dish)	hongo malo
8. *Lactarius* cf. *villosus* Clem. *OHT 10*	*pizutnanácatl* (See *A. muscaria*)	hongo malo
9. *Ramaria abietina* (Pers.) Quél. *AM 1600*	*Xelhuas* del veneno (*xelhuas* = broom, a poisonous broom)	hongo malo
10. *Leccinum aurantiacum* (Bull.) Gray *AM 1606*	*tepexotoma* (*tepetomatl* = madroño tree. Is a *xotoma* growing around madroños (*Arbutus* spp.)	hongo malo
11. *Ramaria abietina* (Pers.) Quél. *AM 1600*	*xelhuas* del veneno (*xelhuas* = broom, a poisonous broom)	hongo malo
12. *Ramaria apiculata* (Fr.) Donk *E-T 2304*	*xelhuas* del veneno (See *R. abietina*)	hongo malo
13. *Ramaria concolor* (Corner) R. H. Petersen *AM 1601*	*xelhuas* del veneno (See *R. abietina*)	hongo malo
14. *Russula* cf. *fragilis* Vittad. *AK 2924*	*pizutnanácatl* (See *A. muscaria*	hongo malo
15. *Russula grisceacens* (Bon & Gaugué) Marti *AK 2939*	*pizutnanácatl* (See *A. muscaria*	hongo malo
16. *Russula murrilli* Burl. *AM 1613*	*pizutnanácatl* (See *A. muscaria*	hongo malo
17. Xerocomus truncatus (Singer, Snell & E. A. Dick) *OHT 03*	*xotomarabia* (It is a poisonous *xotoma*)	hongo malo

While gatherers are on forays, they exchange information about their finds. For example, they talk about the difficult access in certain locations, the form and color of different mushrooms, and the size and presence and absence of certain structures. FIGURE 2 shows gatherers from San Isidro with mushrooms collected in the forest of La Malinche.

FIG. 2. Nahua from San Isidro collecting wild edible mushrooms in to the forest.

Morphology

San Isidro residents can name most parts of a mushroom: the cap, the veil, the cap context, the gills, the scales, the ring and the sac. FIGURE 3 shows the Náhuatl names that the San Isidro villagers have given to each part.



Mushroom
=nanácatl
=hongo
Cap
=izontecotl
=sombrero
Scales
=zitlal
=estrellas
Cuticle
=iyehuayo
=pellejito
Context
=ichito
=carnita
Ring
=iyehuayo
=pellejito
Stipe
=icuaxo
=palito
Volva
=iyehuayo
=pellejito

FIG. 3. Náhuatl terms for mushroom structures.

Categories of mushroom use

There are four main categories of mushroom use in San Isidro: food, trade, insecticide and medicine.

Food

Edible mushrooms are called "cualinanácatl," which means "good mushroom." San Isidro villagers know approximately 58 mushroom names in Náhuatl and 39 in Spanish, which correspond to 31 edible species. The mushrooms preferred because of their taste are *Gomphus floccossus* ("tlapitzal"), *Ramaria* spp. ("xelhuasnanácatl") and *Boletus* spp. ("xotoma"). Each family has its own special way of preparing and eating mushrooms. Mushrooms might be stewed, put in quesadillas, scrambled with eggs, served in a mole or cooked with chile.

Commerce

Of the 220 interviewed, 21% sell the mushrooms they find. Wild mushrooms are sold "for the ranch" and "for the market". "For the ranch" is the most common sale and involves going to nearby villages and peddling door to door. Vendors have certain customers who buy their mushrooms every year; vendors tend to go directly to those houses first.

"For the market" sales take place at a local market, where mushrooms are put in small piles in vendors' stalls. This activity takes place mainly in San Pablo del Monte's municipal marketplace. The mushrooms are sold by the kilo, by a portion halved by hand or by the piece, depending on the species. Only large mushrooms, such as *Amanita caesarea* ("ayocóchitl"), *Boletus atkinsonii*, *B. pinophilus* ("*xotoma*") and *Gomphus floccosus* ("tlapitzal"), are sold individually.

Insecticide

The only species used as an insecticide is *Amanita muscaria*. The flesh of the mushroom cap is mixed with sugar and put in dish in a high place in the room. The mixture is supposed to attract and kill flies. This use was mentioned by 1.4% of the respondents.

Medicine

Only *Ustilago maydis* serves a medicinal purpose for 37% of those interviewed. One use is to spread the spores of the dried mushroom on a wound. It also can be used to moisturize dry lips, heal wounds, dry the navels of newborns, to heal baby rashes (in powder form), to stop hemorrhages and to help heal animal bites. The mushroom also is prepared as a tea to alleviate dehydration caused by the consumption of too much alcohol.

Classification criteria

Texture and consistency are important selection criterions for mushrooms merchants. Mushrooms are classified either as "plain" or "of higher quality". "Plain" mushrooms are brittle, fragile, small and easily damaged during transport. Because they need care, they are placed in the upper part of the collection basket or in a separate container. Examples of such mushrooms are *Clitocybe gibba* and *C. squamulosa* ("izquilo"), *Ramaria* spp. ("xelhuas"), *Hebeloma* cf. *mesophaeum* ("ocoshal"), *Amanita tuza* ("cuatlamanil"), *Laccaria bicolor* ("xocoyule") and *Hygrophorus chrysodon* ("xilonananácatl").

Mushrooms considered to be of the best quality are those that have a firmer and more enduring texture, are large and are not affected by transportation. Examples include *Gomphus floccosus* ("tlapitzal"), *Amanita caesarea* ("xochilnanácatl"), *Boletus pinophilus* ("xotoma"), *B. atkinsonii* ("tlacuahuacxotoma") and *Lyophyllum* spp. ("xuletl"). San Isidro villagers like to collect solid mushrooms because these are generally of good quality and only a few are discarded. Nevertheless, they collect all the mushrooms they can find so that they will have more to sell and eat. Mushrooms are carried in baskets, boxes and plastic bags.

Hot-cold classification

Classification of food and other elements of the universe as "cold" or "hot" is an important element of the

Latin-American cultures (for a detailed explanation see Foster 1979 and Montoya *et al*. 2002). According to this classification, mushrooms in several parts of México are considered to be cold. In San Isidro, they are considered "cold" by 69% of those interviewed and hot by 3%. The first criterion (cold) is associated with a minor stomach ache that some experience after eating a lot of mushrooms. Respondents think that mushrooms are cold because they grow in the forest where it tends to be cold. Some (3.1%) answered that mushrooms are "hot" because they need the heat of the sun to fruit or because they upset the stomach.

Classification by use

San Isidro residents put mushrooms into two categories: good mushrooms ("cualinanatl" = hongo bueno = good mushroom) and inedible mushrooms ("pitzunanácatl"). The most important are the edible mushrooms. This is evidenced by the many names they have been given, the knowledge of where and when they grow, the time spent looking for them, price and the fact that they choose to eat these species more than any others.

Seventeen poisonous species, which had seven Ná- huatl names (TABLE II), were collected. In Spanish, they are called "hongos malos" or "hongos venenosos" while, in Náhuatl, the terms are "pitzunanácatl" (= hongo de puerco = mushroom of the pig) and "zitlalnanácatl" (= estrella-hongo = star mushroom). The latter refers to the white scales on the cap of *Amanita muscaria*, a fungus widely known in the San Isidro area and considered poisonous by most respondents.

Some add the word "rabies" to fungi considered poisonous, such as *Xerocomus truncatus*, which is named "xotomarabia". Poisonous fungi have no use whatsoever and are considered harmful, with the exception of *Amanita muscaria*, used as an insecticide. Many San Isdidro residents believe that all edible mushrooms have a poisonous double. For example, the double for *Amanita caesarea*, known as "ayoxó- chitl," is *Amanita muscaria* ("citlalnanácatl" or "ayoxóchitl de veneno").

TABLE III lists the criteria the villagers use to identify edible and poisonous mushrooms. To be certain that they have collected an edible species, gatherers always pay particular attention to the morphological structures of each mushroom gathered.

TABLE III. Criteria used to distinguish between a poisonous and an edible mushroom

Poisonous fungi	Edible fungi
* When you cut the mushroom it turns either green or purple	* When you cut the mushroom it does not stain green or purple
* When you taste a piece of the mushroom, it burns/stings the tongue	* When you taste a piece of the mushroom, it does not burn/sting the tongue
* Bad odor	* Pleasant odor
* Tastes bitter	* Sweet taste
* There is no presence of worms	* Presence of worms
* Presence of scales on the cap	* Without scales on the cap

The growing season

In the case of San Isidro Buensuceso, mushroom season begins in March and ends in September, with June, July and August producing the most mushrooms. Mushrooms can be divided into several categories according to when they fruit. The first group includes those that need only a little humidity. These appear from March to June and include *Agaricus campestris*, *Amanita tuza*, *Hebeloma* cf. *mesophaeum*, *Lyophyllum decastes* and *Russula delica*. Some San Isidro residents believe that "xoletl" (*Lyophyllum decastes)* is edible only if it is collected before June 24; they believe it is poisonous after that date.

The second group includes mushrooms that need a lot of moisture to fruit. These appear from July until September and include: *Amanita caesarea*, *Armillaria mellea*, *Boletus atkinsonii*, *Laccaria bicolor* and *Suillus* *pseudobrevipes*. Species that emerge at the end of rainy season (the third group) include: *Cantharellus cibarius*, *Clitocybe gibba*, *Gomphus floccosus*, *Helvella crispa*, *Helvella lacunosa*, *Hygrophorus chrysodon*, *Lactarius salmonicolor*, *Morchella* spp. and *Ramaria* spp.

Data on where mushrooms grow

San Isidro gatherers know exactly where to look for each type of mushroom. TABLE IV presents this information.

TABLE IV. Places where mushrooms grow

Outside of the forest	
Plains and meadows	*Agaricus campestris* (ayutzi)
	Lycoperdon perlatum (xiteburo)
On *Agave* spp. (maguey)	*Pleurotus opuntiae* (mesonanácatl)
Around agricultural fields (*Zea mays*) on oak trunks (*Quercus* sp.)	*Armillaria mellea* ("tehtecui")
Road sides	*Amanita tuza* ("cuatlamanil")
In the forest	
In fir forest (*Abies religiosa*) ("oyametl")	*Clitocybe gibba* ("izquilo") *Gomphus floccossus* ("tlapitzal") *Helvella crispa* ("gachupi") *Helvella lacunosa* ("charronanácatl") *Hygrophorus chrysodon* ("xilona") *Lactarius salmonicolor* ("chilnanácatl") *Morchella esculenta, M. elata* ("olonanácatl") *Ramaria* spp. ("xelhuas")
In pine forest (*Pinus* spp.) ("ocotl")	Associated to grass (*Agrostis* sp. and *Mulhenbergia* sp.) *Boletus pinophilus, B. atkinsonii* ("xotoma") *Suillus granulatus, S. pseudobrevipes* ("poposo") *Amanita caesarea* ("ayoxóxitl") *Cantharellus cibarius* ("tecosa") *Chroogompus jamaiscensis* ("tlapaltecosa") *Hebeloma* cf. *mesophaeum* ("ocoxal") *Laccaria bicolor* ("xoxocoyule") *Lyophyllum decastes* ("xuletl")
In oak forest (*Quercus* spp.) ("tlacuauatl")	*Armilaria mellea* ("tehtecui") *Lactarius indigo* ("cacaxnanácatl") *Hypomyces lactifluorum* ("chilnanácatl de ocotl") *Boletus* sp. ("xotoma")

Frequency of mention

The free-listing technique, described earlier, yielded a total of 52 traditional and common names for 29 mushroom species. TABLE V shows how often each species was mentioned.

According to the study findings, more than 90% of those interviewed mentioned these mushrooms: *Gomphus floccosus*, *Ramaria* spp., and *Boletus pinophilus*. Other mushrooms also appreciated and mentioned by more than 50% of the participants were: *Amanita caesarea*, *Cantharellus cibarius*, *Clitocybe* spp., *Laccaria bicolor*, *Lyophyllum decastes*, *Morchella* spp. and *Russula delica*. The mushrooms mentioned by more than 20% of the interviewees but fewer than 50% were: *Hebeloma* cf. *mesopheum*, *Armillaria mellea*, *Hygrophorus chrysodon*, *Suillus pseudobrevipes*, *Chroogomphus jamaiscensis*, *Helvella crispa*, *Lactarius indigo*, *Agraricus campestris* and "*totoltenanácatl*" (a species not gathered by San Isidro villagers).

TABLE V. Frequency of mushroom mention using free listing

Scientific name	Traditional name	Women	Men	Total
Gomphus flocossus	*tlapitzal*, cornetas	22	21	42
Ramaria spp.	*xelhuasnanácatl*	19	23	42
Boletus pinophilus	*xotoma*	21	20	41
Cantharellus cibarius	*tecosananácatl*	19	16	35
Russula delica	*cuatecax* (*nanácatl*), *iztacnanácatl*	18	16	34
Amanita caesarea	*ayoxochitl*	13	7	30
Laccaria bicolor	*xoxocoyuli*	16	19	30
Lyophyllum decastes	*xuletl, xuletlnanácatl*	16	16	28
Clitocybe gibba, C. squamulosa	*izquilo, izquilonaná catl, izquilon, totomoch*	15	11	26
Morchella elata, M. conica	*olonanácatl* olotitos, suéter	14	10	24
Hebeloma cf. *mesophaeum*	ocoxalnanácatl (sh), *ocoxoletl, xuletl* de *ocoxal*	12	9	21
Armillaria mellea	*tehtecui*	12	7	19
Hygrphorus chrysodon	*xilonananácatl*	8	9	17
Suillus pseudobrevipes	*poposo*	8	7	15
Chrogoomphus jamaiscencis	*tecosa cafecita, t.* de toro, *tlapaltecusa, tecosan morado*	9	5	14
Helvella lacunosa	*gachupinanácatl, gachupi, g. blanco*	6	6	12
Lactarius indigo	*cacaxnanácatl, cuatecax azul*, h. azul	7	5	12
Lycoperdon perlatum	*xiteburo, xitetl*	2	1	3
Agaricus campestris	*ayutzi*	8	2	10
	totoltenanácatl	3	7	10
	cefamile	4	4	8
Lactarius salmonicolor	*chilnanácatl*	3	5	8
Amanita tuza	*cuatlamanil*	3	5	8
Pleurotus opuntiae	*menanácatl*, hongo de maguey	4	3	7
Amanita muscaria	*citlalnanácatl*	2	4	6
Lyophyllum sp.	*tlacuahuacxuletl*	4	1	5
Lactarius salmonicolor	*chilnanácatl de oyametl, oyamechilnanácatl*	3	1	4
Helvella lacunosa	*gachupin* negro, charro	1	2	3
	cuatlillzi	1	2	3
	solnanácatl	2	1	3
Boletus atkinsonii	*tlapalxotoma*	0	2	2

TABLE VI lists how many of each of 17 species were found in the local forest. These figures are compared with data on the frequency of mention and prices. Mushroom names were ranked from most significant to least significant, according to the number of people who named them. The table presents abundance information only for the species mentioned in the free listing and for which prices were available. The Spearman correlation index between frequency of mention and abundance had a value of 20.51, while that between frequency of mention and price had a value of 0.39. The most abundant species in the study area were *Laccaria bicolor*, *Morchella* spp., *Clitocybe* spp., and *Helvella lacunosa*. *Amanita caesarea*, *Gomphus floccosus*, *Ramaria* spp., *Boletus pinophilus*, *Laccaria bicolor* and *Helvella crispa* fetched the highest prices.

TABLE VI. Comparison between frequency of mention, abundance values and selling prices of 17 species of wild mushrooms

Scientific name	Mention frequency (Number of persons who mention each species)	Abundance values (Number of fruit bodies in 1600 m^2)	Selling prices (2000)	
			Pesos per kilogram	US Dollars per kilogram
Gomphus floccosus	42	9	$30.00	3.19
Ramaria spp.	42	0	$30.00	3.19
Boletus pinophilus	41	2	$30.00	3.19
Cantharellus cibarius	35	2	$8.00-10.00	0.85-1.06
Russula delica	34	10	$25.00	2.66
Lyophyllum decastes	33	12	$15.00	1.6
Amanita caesarea	30	0	$70.00	7.45
Laccaria bicolor	30	225	$30.00	3.19

Lycoperdon perlatum	3	18	$8.00-10.00	0.85-1.06

Discussion

San Isidro Buensuceso is an important community, from a cultural point of view, given that its residents retain many of their indigenous traditions, maintain a set of typical social and family values, still use forest products for their subsistence and communicate in their indigenous (Náhuatl) language.

This study obtained detailed information about several aspects of traditional mushroom knowledge. According to the information gleaned from the older residents, we hypothesize that mushrooms have played a role in the daily lives of this community for a very long time. Unfortunately, no previous studies confirm this information.

Based on the number of mushroom species (33) used by the people of San Isidro, the number of names in use (115) and the information about when and where each species grows each season, one can say that the traditional mushroom knowledge in San Isidro Buensuceso is similar to that of other Nahua communities, such as Hueyapan, Morelos (De Ávila *et al*. 1980), Santa Catarina del Monte, in the Valley of México (González 1982), Parres, D.F. and El Capulín (Gispert *et al*. 1984). A comparison of the few ethnomycological Nahua studies to date shows that each has had its own focus, but there is a commonality as well; they all addressed traditional nomenclature, where and when mushrooms grow, how mushrooms are rated according to the "hot-cold" system and how certain species are cooked.

Descriptions of Nahua knowledge show that, until today, in different places in México, this indigenous group uses mushrooms both for food and for commercial purposes. Of course, we do not really know how important mushroom commerce is. For example, it appears to be very important in some places, such as Santa Catarina del Monte, and not so important for San Isidro residents. On the other hand, the knowledge of this resource is detailed, probably because mushroom collection and commerce began deep in the past (Martín del Campo

1968).

From the total known species in San Isidro, the villagers eat 67% of them and various recipes are used to prepare and cook each one. Mushrooms help provide a nutritional complement to an otherwise monotonous diet (Montoya *et al*. 2000). For example, mushrooms provide protein in a diet that normally consists of beans, tortillas and sauce. To that end, it is important that species are selected that can be cooked together in one dish, with consideration for taste and texture.

The activity of collecting is equally important, because it permits Nahua to preserve their traditional mushroom knowledge, which is passed onto their children during forays or when mushrooms are sorted for sale or when they are prepared for meals at home. Similarly, they pass on information concerning how to distinguish edible mushrooms from those considered poisonous. This has helped reduce incidences of mushroom poisonings.

A primary means of identifying mushrooms is the morphology of the fruit bodies. San Isidro villagers recognize and can name all the parts of mushrooms in the *Agaricales* order (gilled mushrooms). Estrada- Torres (1989) concluded that this knowledge might be determined by the influence of a species, or group of species, that had a major cultural value in a region. The results of the current study indicate that this does not appear to be the case in San Isidro, where the most important mushrooms are not Agarics.

In addition to their use as food at home, edible mushrooms are sold in neighboring communities. Although this activity does not seem that important in this region (considering how few people - 21% - are engaged in it), it does produce additional income. Only a few use mushrooms as medicine or insecticide (37% and 1.4%, respectively). Nevertheless, Nahua have some knowledge of such uses, which increases their potential pharmaceutical resources. There has been no evidence that San Isidro Buensuceso residents use hallucinogenic mushrooms for ceremonial or medicinal purposes, despite what historical records of Tlaxcala say about their use by the ancient Nahua.

Based on the study's findings, it seems that San Isidro villagers take a utilitarian approach when classifying their mushrooms, because they always refer first to the edible ones, which they use in great numbers. They put "citlalnanácatl" (*Amanita muscaria*) or "pitzunanácatl", the poisonous ones, in second place and use only a few of them.

San Isidro villagers gather the most and most diverse number of edible mushrooms in the area they call "the mountain". Based on the number of species found, forests with *Pinus* and *Abies* provide the type of vegetation that promotes the greatest diversity of mushrooms and produces the species that are most valued from a commercial point of view. Forests of *Abies* are especially important because that is where *Gomphus floccosus*, the most sought after mushroom in the area, thrives. Several hunters rely on *Sarcodon* sp. to indicate the presence of that species. They believe that, if *Sarcodon* sp. is present, they are certain to find several fruit bodies of *Gomphus*. This is odd because *Sarcodon* is dark and difficult to see, whereas *Gomphus* is bright orange. Perhaps because both species grow at the end of the rainy season, gatherers make the connection.

Away from the mountain, oak forests are important because of the species that grow there. Nevertheless, San Isidro residents believe that mountain mushrooms are superior and have a much better flavor because they grow where there are many trees. Our findings on where and when mushrooms grow agree with those published by González (1982) and Gispert *et al*. (1984).

The results on the cultural importance of the mushrooms used by the San Isidro villagers, as indicated by the free listing, suggest that *Gomphus floccosus*, *Ramaria* spp. and *Boletus pinophilus* are the most important mushrooms to this community. The efforts spent on their collection and the fact that only few are found are the determinants of price. They are the ones most sought after, although they fruit in remote places. Those most valued in this community are not the gilled mushrooms, as was suggested by Estrada-Torres (1989) for other communities in the country.

The mushrooms mentioned earlier are the ones most valued, and almost everyone in San Isidro is familiar with them. At the very least, they cook *Gomphus floccosus* in various ways. The sale of these mushrooms produces a higher income than the sale of the more fragile and smaller species, which also require more energy to collect.

Although Lincoff (1977) concluded that *Gomphus floccosus* can upset the stomach, this does not seem to be the case in México. Moreover, it is surprising to see how popular this mushroom has become in San Isidro. Nevertheless, because it is bitter, a knowledge of the mushroom is needed to cook it properly. The cleaning process involves removing the scales on the cap and the veins of the hymenophore. San Isidro residents, in addition, recommend boiling the mushroom before cooking it with other ingredients; this mushroom generally is eaten in a mole or in tamales.

The Spearman correlation indices for frequency of mention in the free listing and number of mushrooms found and for frequency of mention and selling prices were low (20.51 and 0.39, respectively). The reason for this is that a high frequency of mention does not always correspond with abundance or price. It was a surprise to discover that the correlation between abundance and frequency of mention was not positive, indicating that, most of the time, a mushroom found only rarely is mentioned frequently. This means that the most abundant resources are not always the most appreciated, and because a great deal of time and effort are spent looking for the rarer but particularly popular species, prices are higher. Thus, the abundance of mushrooms and prices are factors that contribute to the attribution of cultural significance of at least some species. But, because other factors also could affect how important each species is considered to be, our findings only partially support the hypothesis posed earlier. In the following paragraphs, we show some of the instances where at least one of the predictions of this study (correlation between frequency of mention and abundance or price) is satisfied.

Gomphus floccosus, *Ramaria* spp., *Boletus pinophilus*, *Russula delica* and *Lyophyllum decastes* were mentioned most frequently and brought in the highest prices, but their numbers in the forest were among the lowest. Although *Cantharellus cibarius* are scarce and culturally important, neither fact is reflected in its price.

Amanita caesarea fetches the highest price ($7.44/kg) of all the mushrooms that are sold by San Isidro villagers and is found rarely in the areas studied, but these facts are not reflected in this mushroom's cultural value, which was lower than those mentioned above. The scarcity of this species must be due the fact that it develops in very specific micro-environments, which were not included in our sample areas. *Laccaria bicolor* is the most abundant species and fetches a relatively good price, even though it is generally mixed with other marketed species. Even though it is not the most popular species, one can conclude that, for 68% of those interviewed, it has a relatively high cultural value.

On the other hand, *Clitocybe gibba* and *Morchella* spp. were mentioned by more than half of those interviewed and are among the most abundant species, yet their prices are among the lowest. *Helvella crispa* and *Helvella lacunosa* both are abundant and expensive, yet they received the least mention in the free listings. *Chroogomphus jamaicensis*, *Hygrophorus chrysodon* and *Lycoperdon perlatum* were mentioned by less than half of those interviewed, and their abundance, as well as their prices, were low.

Although the frequency with which a species was mentioned is a good indicator of its cultural significance, it is necessary to confirm this conclusion with other studies that consider additional variables, such as abundance, selling prices, knowledge of where mushrooms grow, the fruiting season, information on morphology, recipes used, eating preferences and consistency of fruiting bodies. These variables should be factors in determining more precisely the cultural value of mushrooms in this and other Mexican communities.

Acknowledgments

We greatly appreciate the helpful comments by Dr. Alejandro Casas Fernández of the Instituto de Ecología, Campus Morelia, Michoacan. We also thank Florencia García for the first English translation and Gundi Jeffrey for her help with editing and revising that translation. Translation of Náhuatl names was supported by María Rosario Xochitiotzin, a specialist in lingustics. We also are grateful to Lorenza Pérez Flores, Don Pánfilo and all the residents of San Isidro, who made this paper possible. We also wish to thank Coordinación General de Ecología of Tlaxcala for its support for this research in Malinche National Park. This study was supported by a grant of CONACYT, with additional financing from PROMEP/UATLAX-29.

The Hallucinogenic mushrooms of Mexico: An adventure in ethnomycological exploration

by

R. Gordon Wasson

This paper, illustrated with slides, was presented at a meeting of the Division on January 23,1959.

New York, N. Y

original text: https://bibliography.maps.org/resources/download/15622

Our inquiries into the hallucinogenic mushrooms, after six years and more of research, are now at the end of their first phase.

In Paris, a book on our mushrooms has just been published by the *Muséum National d'Histoire Naturelle*. Handsomely illustrated, it deals with every aspect of this strange mushroom complex - anthropological, linguistic, historical, archeological, mycological, chemical, psychological, and religious - and even the initial steps in the therapeutic use of the active agent in the mushrooms. Roger Heim, director of the museum, is the author, and he has done me the signal honor of joining my name to his on the title page. On January 29, 1959, an exhibition illustrating our mushrooms and our experiences with them opened in the American Museum of Natural History, New York, N.Y., to which the Paris Muséum has generously lent its collaboration. Thus publication of this paper offers a timely and welcome opportunity to report on our remarkable adventure in ethnomycology*.

> * "Ethnomycology" was a word coined by us, after the analogy of ethnobotany, to signify the role played by mushrooms in the history of human cultures. It first appeared in print in 1954 in an invitation sent out by the American Geographical Society, New York, N.Y., to a lecture that we were to give before that body.

It was in September 1952 that my late wife and I first learned of the existence of a mushroom cult among the Indian tribes of southern Mexico. Immediately we undertook, in our spare time, to learn all that had been published about it. There were only three modern papers on this cult that contributed helpful information. However, in the old writings about Mexico, dating mostly from the Sixteenth and Seventeenth Centuries, we found a number of references to it, all of them of absorbing interest to us. We undertook to make an anthology of these quotations, upwards of a score of them, some of their existing only in manuscripts of the time. We were helped in this search for the sources by kind friends, notably by those eminent authorities on ancient Mexico, Robert J. Weitlaner and his daughter, Irmgard Weitlaner-Johnson. We analyzed these quotations, pinpointing on the map of Mexico the places to which they referred, collating the descriptions of the fungi, and scrutinizing what was said about the use of the mushrooms. We undertook to peruse the archeological record in Meso-America: and what an extrordinarily complex, rich, and enigmatic record it is! We believe that we have discovered, for the first time, our sacred mushrooms in that record. In our forthcoming book we publish the text of all our quotations, and we submit the archeological evidence for the mushroom cult to the judgment of those qualified in this thorny field of recondite learning.

Here a number of questions will occur to the mycologist. What mushroom or mushrooms are worshipped? Many of the old writers speak of the visions that these fungi cause. Do they really produce visions? If so, what is the active agent in them that provokes such a response? What is its molecular structure? Could it be used in therapeutics?

Then there is the anthropological problem. What were the geographical limits of the cult in the old days and where does it survive now, if at all? What role does the mushroom play in the lives of the Indians? The cult lingers in the areas where it existed earlier, in the uplands of southern Mexico, roughly from the latitude of Mexico City to the Isthmus of Tehuantepec. It survives feebly if at all in the cities and surrounding country, but in full vigor off the highways, in Indian villages where the native languages are still in current use. In these remote places the sacred mushroom holds the entire population in its grip. The anthropologists have overlooked it simply because they have not asked about it and the Indians do not volunteer to talk about it.

Not all anthropologists are temperamentally suited for studying such a phenomenon as the mushroom rite among the primitive Indians of Mexico. The anthropological discipline schools its neophytes in a respect for hard, down-to-earth facts. These students are prepared to arrive at the systems of kinship and marriage among the peoples they study, the rules of land tenure and exploitation, the methods of manufacture of textiles and other artifacts, the customs governing the exchange of goods, the calendar systems, and the native cosmologic and eschatological ideas. By the nature of the archeological discipline, there is a natural selection of persons who are not poets, not mystics, not skilled in assessing subjective emotions. Yet in primitive man the poetic element, the religious feeling, exists, and it richly deserves the attention of the modern world. The difference I speak of is the difference between the beauty of a bird in flight and the taxonomist's description of that same bird's flight muscles; between the breathless beauty of a rainbow and the physicist's spectrum analysis of that same rainbow. The divine mushroom that causes the eater to see visions plays perforce a vital role in the inner life of the Indian, that aspect of his life which he is reluctant to discuss with strangers of another race and language, and doubly so if those strangers would not enter into the experience sympathetically. The anthropologist who explores these subjects should possess the soul of a poet and the tact of a father confessor, yet he must not let his own imagination run away with him. He must observe, with the eye of a poet, the role of the mushroom in a primitive culture far removed from his own, and confine himself to that function. His task resembles the problem of a translator of poetry, who must possess poetic feeling and yet harness his own Pegasus to another man's imagination. How seldom do we meet with a good translation of poetry! So it is, I feel, with the anthropologist's study of the subjective religious life of the Mexican Indian. Trained from the beginning to an austere respect for nuggets of fact, most anthropologists - not all - are ill-prepared to enter into the poetic world of the subjective life of the people they are studying, for exploring the world revealed by the sacred mushroom. We at least are alive to the problem. In our writings about the mushroom cult we have tried to escape the Scylla of dry factualism and also the Charybdis of unbridled imagination.

Each year since 1953 we have made expeditions to southern Mexico, to the remote mountain fastnesses where the mushroom cult survives, traveling intentionally in the rainy season, by mule over mountain trails, often in the rain, to live in the Indian villages where the Spanish language is known only to a few head men. Our first and essential task was to win the confidence of the Indians. Their initial reaction to our presence was always reserved, occasionally hostile: the Indians have had contact with white men for centuries, and we are not viewed with the favor one should like. Our attitude was that of humble suppliants coming to learn the secrets of the sacred mushroom for the benefit of our own people. After an interval the Indians met us more than halfway.

From the beginning we had three objectives: (1) to obtain some of the sacred mushrooms; (2) to attend the ceremony in which they are eaten; and (3) to share in the eating. We were intent on learning everything about the cult: how and when the mushrooms are gathered; how they change hands and reach the ultimate consumer, the Indian (and Spanish, if any) names for the mushrooms; the meaning of those names; the manner of performing the ceremony in the different tribes and villages; the purpose of the ceremony; whether the mushrooms are really psychotropic; what one experiences on eating them; and the dosage. We were eager to get photographs and tape recordings of the ceremony, to study the words linguistically and religiously, to identify the mushrooms, to isolate the active agent (if any), to describe this agent's molecular structure, to define its properties, and, finally, to place our mushroom cult in the context of what is known of primitive religious behavior. A little more than six years have passed since we began to devote our spare time to this avocation, and we have now attained all these objectives in some degree.

The identification of our mushrooms proved much more complicated and exciting than we had imagined. The old writers had given inadequate descriptions of these fungi, but what they said indicated that there were several species. (After all, who can blame those authors for their inadequacies, since the science of mycology had not yet been born?) Although we expected to find several species, our discoveries went far beyond this. Each region that we visited makes use of species peculiar to itself, only a few species turning up in more than one region. The sacred mushrooms of Mexico belong, for the most part, to the genus *Psilocybe* and, except for one or two species, they are new to science. Genuinely psychotropic and hallucinogenic, they are the following, arranged according to the regions in which they were found:

Sierra Mazateca: (1) *Psilocybe mexicana* Heim; (2) *Psilocybe semperviva* Heim and Cailleux; (3) *Psilocybe caerulescens* Murrill var. *Mazatecorum* Heim: (4) *Psilocybe yungensis* Singer & Smith;* (5) *Psilocybe acutissima* Heim; (6) *Stropharia*** *cubensis* Earle (synonym: *Psilocybe cubensis* (Earle) Singer); and (7) *Conocybe siligineoides* Heim.

* This species poses a problem. Ingested by Thomas Davis and RGW in the field, it proved to be psychotropic and (in RGW's case) hallucinogenic. Subsequently in the laboratory the tests for psilocybin were negative.
** The psychotropic activity of this species was recognized by the Indians but, owing to paucity of material, has not been proved in the "laboratory or by experiment on ourselves".

Slopes of Popocatepetl, Valley of Mexico: (8) *Psilocybe aztecorum* Heim. Tenango del Valle: (9) *Psilocybe wassonii* Heim (synonym: *Psilocybe muliercula* Singer & Smith).

San Agustín Loxicha, in the Sierra Costera; (10) *Psilocybe zapotecorum* Heim (also No.1, and two other species of unknown identity).

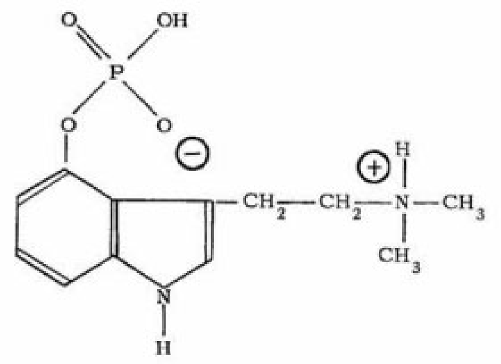
Mixería, region of San Juan Mazatlán: (11) *Psilocybe hoogshageni* Heim; (12) *Psilocybe cordispora* Heim; and (13) *Psilocybe mixaeensis* Heim (also No.1).

Yaitépec, in the Chatino country, Sierra Costera: (14) *Psilocybe caerulescens* Murrill var. *nigripes* Heim (also Nos. 1 and 10).

Sochi apam in the Chinantla, No. 1?

On the periphery of the area where mushrooms are used for divination, two species serve for that purpose that we believe riot to be psychotropic. Their phallic suggestiveness obviously explains their role. In Tenango del Valle the Indians consume *Cordyceps capitata* in association with hallucinogenic *Psilocybe* sp. In one corner of the Chinantla the *curandera* crushes and eats *Dictyophora phalloides* to heighten her divinatory powers.

Roger Heim of Paris, our mentor in all matters mycological, has devoted himself to the classification and study of our mushrooms and, in 1956, he joined us in the field. He identified them as Basidiomycetes and, with the aid of his young assistant Roger Cailleux, he succeeded in cultivating almost all of the fourteen species of Mexican hallucinogenic agarics in the *Laboratoire de Cryptogamie* in Paris, at first in sterile, artificial media, later in compost in hothouses, thus freeing us of our dependence on Mexico for our supply of raw material. In the Sandoz laboratories of Basel, Switzerland, with material supplied from Paris, a research team headed by Albert Hofmann and including Heim, A. Brack, and H. Kobel succeeded in large-scale culture of *Psilocybe mexicana*, in sterile conditions on artificial media, isolating two distinctive substances. They called one of them psilocybin and the other psilocin, and they reduced psilocybin to a pure white crystalline powder, arrived at its molecular structure, and synthesized this compound in full (0-phosphoryl-4-hydroxy-N-dimethyl-tryptamine). The active agent is not an alkaloid nor a polypeptide but an indole structure. It contains an atom of phosphorus and, as such, is a substance new to chemical science. Psilocin, which is present in much smaller amounts, is a dephosphorization of psilocybin.



Physical and chemical data: empirical formula, $C_{12}H_{17}O_4N_2P \cdot CH_3OH$; molecular weight, 284.3•32; melting point, 200 to 210°C. with decomposition; solubility, in 120 parts of water at 20°C.; and pH, 5.3. Keller color reaction: 0.1 mg. of psilocybin dissolved in 1 cc. 0.01 per cent ferric chloride containing acetic acid and stratified with 1 cc. concentrated sulfuric acid. After mixing, a violet color is obtained.

For our part, my wife and I concentrated our attention on the anthropological side of the mushroom cult. In the remote Indian villages the Indians regard the psychotropic mushrooms as holy. They fear and adore them. Although the mushrooms are nowhere any longer called by the Aztec term *teo-nanácatl*, "God's flesh," the Indians regard them as the key to communication with the Deity. The mushrooms today are eaten behind closed doors, in the silence and darkness of the night. They do not change hands in the market place for money, but are delivered privately, carefully wrapped up, perhaps in a banana leaf. The Indians do not discuss the sacred mushrooms in gatherings: you learn about them talking in a whisper with a friend who trusts you, preferably at night. *Es muy delicado*, it is very perilous, the Indians say, not to be taken lightly, and only as a sacrament. There is nothing in common, absolutely nothing, between these sacred mushrooms and our use of alcohol. The vulgar jocularity with which fully civilized peoples sometimes talk of a "binge" or a "jag" is alien to the Indian with his mushrooms. The effects are wholly different. With the mushrooms there is no hang-over, no obfuscation of the memory, and it seems that one does not become addicted to the mushrooms as one sometimes does to alcohol and certain other drugs. The dosage remains the same throughout life. The mushrooms are taken when a grave problem needs to be resolved and, I believe, only then. Perhaps there is illness in the family and the mushroom is consulted to learn whether the patient will live or die. If the verdict is for death, the family does not wait but immediately prepares for the funeral, and the sick person loses the will to live and shortly afterward gives up the ghost. If the verdict is for life, the mushroom will tell what must be done if the patient is to recover. Or, again, if a donkey has been lost or if some money has been stolen, the mushroom is consulted and gives the answers. Among these unlettered folk, speaking languages that are not written, there is often no news of an absent member of the family, perhaps one who has gone as a "wetback" to the United States. Here the mushroom, as a postal service, brings tidings of the absent one, whether he is alive and well, or sick or in jail, or prosperous or poor, or whether he is married and has children.

The method of taking the mushrooms varies. In the Mixe country the mushrooms are consumed privately by the suppliant, with only one friend present, to attend to what might happen and be a witness. In other regions a *curandero* or healer, who takes the mushrooms and who may serve them to others present, is called in. We know of two quite different rites that the *curandero* may use. In one of them the mushrooms are superimposed on the ceremony of divination that is common to all Meso-America, a much larger area than the mushroom country. In this ceremony the *curandero* casts kernels of maize, and according to the way they fall reads the answers to the questions that are put to him. Of course, there is much more to the ceremony than that: all the accessories to the rite play their part - hen's eggs, turkey eggs, *guacamaya* (macaw) feathers, copal (a resin), cacao beans, tapers of pure beeswax, and *amate*, or wrappings of bark. These accessories play their role with a precision, a nicety, that are equal to the reverence and care with which a priest handles the holy utensils of the Mass. In the mushroom country the *curandero* simply adds mushrooms to this customary ceremony to strengthen the divine power within him.

In the alternative ceremony the *curandero*, having partaken of the divine mushrooms, waits for them to seize hold of him and then chants his supplications to the Almighty to come down and answer the prayers and problems of those present. In this ceremony the *curandero* is esteemed according to the skill he displays in formulating the appeals to God. Today, and I dare say throughout the past, there have been *curanderos* who were frauds, *embusteros* as they are called, but it has been our privilege to know two who were not, and one of them, María Sabina, is a woman of presence, integrity, and intelligence. The *curanderos* are called of God. That is, one becomes a *curandero* because, having taken the mushrooms, they tell one to follow that vocation. The *curanderos* are not organized in a hierarchy: each one practices his calling on his own, like the shamans of Siberia, although they may exchange ideas on occasion with each other. As a class, they are shy, usually living apart on the outskirts of town. It would be well worthwhile, before the tradition is lost, to explore all the villages where the sacred mushroom is consulted, to seek out the most proficient *curanderos*, win their confidence, and explore the recesses of their minds. These agents are the surviving repositories of the Old Religion. I am certain that they would surprise you by the content of their minds and their virtuosity in the discharge of their office.

The sacred mushrooms of Mexico seize hold of you with irresistible power. They lead to a temporary schizophrenia, or pseudoschizophrenia, in which your body lies, heavy as lead, on the *petate*, or mat, and you take notes and compare experiences with your neighbor, while your soul flies off to the ends of the world and, indeed, to other planes of existence. The mushrooms take effect differently with different persons. For example, some seem to experience only a divine euphoria, which may translate itself into uncontrollable laughter. In my case I experienced hallucinations. What I was seeing was more clearly seen than anything I had seen before. At last I was seeing with the eye of the soul, not through the coarse lenses of my natural eyes. Moreover, what I was seeing was impregnated with weighty meaning: I was awe-struck. My visions, which never repeated themselves, were of nothing seen in this world; no motor cars, no cities with skyscrapers, no jet engines. All my visions possessed a pristine quality: when I saw choir stalls in a Renaissance cathedral, they were not black with age and incense, but as though they had just come, fresh carved, from the hand of the Master. The palaces, gardens, seascapes, and mountains that I saw had that aspect of newness, of fresh beauty, that occasionally comes to all of us in a flash. I saw few persons, and then usually at a great distance, but once I saw a human figure near at hand, a woman larger than normal, staring out over a twilight sea from her cabin on the shore. It is a curious sensation: with the speed of thought you are translated wherever you desire to be, and you are there, a disembodied eye, poised in space, seeing, not seen, invisible, incorporeal.

I have placed stress on the visual hallucinations, but all the senses are equally affected, and the human organism as a whole is lifted to a plane of intense experience. A drink of water, a puff of the cigarette, is transformed, leaving you breathless with wonder and delight. The emotions and intellect are similarly stepped up. Your whole being is aquiver with life.

Our friends of Sandoz are offering this active agent for experimentation on the inmates of our hospitals for the emotionally disturbed in Paris and in Lexington, Ky. Will no one try it out on the exceptionally gifted? There is the possibility - I say no more than the possibility - that their powers will be sharpened and they will command insights not given to them in their normal existence.

While we were seeing our visions in the blackness of a tropical night, with the rain pouring outside, the *curandera* was giving voice to her canticles, invoking the deity to come down among us. She and her daughter took turns at singing. At times she would rise and engage in a complicated clapping, slapping, whacking of different parts of her body, with different resonance depending upon the part of her body that she would strike, with a complicated timing of the whacks, the blows being nicely modulated, sometimes struck lightly, sometimes with full power; and she would rotate to the cardinal points of the compass as she performed. There we were, in a humble Indian hut, with our visions and the authoritative voice of the daughter's singing in our ears, and the percussive blows of the mother displaying a ventriloquistic virtue, now here, now there, near at hand, far away, as though we were afloat in space, stroked by breezes, listening to the voice raised in song, and surrounded by the calls of eerie creatures darting around us.

The performance of the *curandera* reaches a climax every twenty or thirty minutes. Then suddenly the singing stops and the mushroom speaks. She whips out the words of the oracle, loud, sharp, with compelling authority, the syllables cutting the night air and the darkness and the silence like a knife. Afterward everyone relaxes, cigarettes are lighted, and there is general conversation in which the *curandera* participates.

After four or five hours of this experience we would all fall into a deep slumber, from which we would awaken some two hours later, refreshed and ready for work - ready, that is, except that the clear recollection or our adventure made work seem unimportant, and the important thing to do was to compare notes with our companions and record in our diary every detail of the nights events.

I have now told you what we have accomplished, in the field and the laboratory, in the past six years. We have rediscovered the sacred mushrooms of Mexico, identified them, isolated the active agent, and proceeded to the determination of its properties. What is there for us to do now? Our field of research broadens as we progress. Let me outline, what seems to me, in the anthropological field, the course to persue. Remember that all I shall say is speculative, awaiting confirmation.

We are dealing here with an authentic form of the religion of primitive men. Let me repeat what I said before: that it would be an error to bracket the hallucinogenic mushrooms with alcohol, as just another drug that serves as an escape for man. The mushroom, despite its potency, is a dying agent. In the primitive world its survival is spotty, although there is evidence that its use was widespread long ago. It survives only in peripheral cultures, among the most isolated and neglected peoples, in Siberia, in Borneo, in New Guinea, until recently in Peru, and in Mexico. At an early stage in the evolution of a culture, it serves as the great mediator with God for peoples who are just beginning to be familiar with the idea of God.

The animal kingdom does not know God; it has no conception of the religious idea. The animal cannot imagine horizons beyond the horizon it has actually seen, a past earlier than it has experienced, a future beyond the immediate future, planes of existence other than this one in which we find ourselves. There must have come a time when man, emerging from his bestial past, first grasped these possibilities, vaguely, hesitantly; when he first knew the awe that goes with the idea of God. Perhaps these ideas came to him unaided, by the light of his dawning intelligence. I suggest to you that, as our most primitive ancestors foraged for their food, they must have come upon our psychotropic mushrooms, or perhaps other plants possessing the same property, and eaten them, and known the miracle of awe in the presence of God. This discovery must have been made on many occasions, far apart in time and space. It must have been a mighty springboard for primitive man's imagination. The secret of the miraculous discovery would be closely guarded, and it would leave little trace, other than by ricochet in folklore, in legend, and in the etymology of relevant words. From the beginning of history there have been seers, mystics, prophets, and poets who have seemed to possess the secret vision of eternal values. They achieved this by fasting and other ascetic practices or, perhaps, as in the case of Blake and Keats, by their abnormal sensitivity. Blake's description of the poetic gift is singularly apt for the experience of the mushroom agape: "He who does not imagine in a stronger and better light than his perishing mortal eye can see, does not imagine at all." The divine mushroom would open up the world of visions to far greater numbers, and the kingdom of God would be within reach of everyone who possessed the sacred secret. The Kingdom of God would be within you.

The ceremony we attended in southern Mexico was a true agape, a love-feast, a Holy Supper, in which we all felt the presence of God, in which the Element carried its own conviction in the miracles it performed within us. The faithful were not obliged to accept the dogma of Transubstantiation in order to know that they had partaken of the body of Christ. (How startling it is that the ancient Aztecs called this Element by the same name that we use for the Bread and Wine of the Eucharist - God's Flesh!) May not the sacred mushroom, or some other natural hallucinogen, have been the original element in all the Holy Suppers of the world, being gradually replaced by harmless Elements in a watering down of the original fearful sacrament? May this not be the explanation of the Archetypes, the Ideas, of Plato? The ancient Greeks never revealed the secret of the Eleusinian mysteries, yet many must have known it and whispered to each other about it. We know only that the initiates drank a potion and later in the night knew a great vision. The Greeks, who were the fathers of pure reason, reserved a portion of their minds for the mystical element, the mysteries of Eleusis, the oracle at Delphi, the daemon of Socrates. No one knows for sure what beverage the ancient Hindus meant by the *soma*, nor what was the origin of the *ling chih* of the Chinese, the divine mushroom of immortality. Here is a missing element in our knowledge of these cultures, one that possibly can now be identified by the methods that we have used in our quest of the sacred mushroom.

There remains one question that some may be asking themselves, and that I gladly answer. How is it that I, a banker, and my wife, a pediatrician, have gone into these remote territories, and how does it come about that I write about these subjects? Our mushrooms impinge on a multitude of disciplines: in science, on mycology, chemistry, psychology, and medicine, in the humanities, on folklore and mythology, philology, anthropology, archeology, history, and religion. How does it come about that laymen without academic qualifications in any of these disciplines are so bold as to address a scientific body on these subjects?

My wife and I began to gather our material long ago, in 1927, on an August afternoon in the Catskills, as we strolled along a mountain path on the edge of a forest. She was of Russian birth and I am of Anglo-Saxon ancestry. I knew nothing of mushrooms and cared less. They were for me rather repellent and, like as not, deadly poisonous. In the years that we had known each other, I had never discussed mushrooms with my wife. Suddenly she darted away from my side: she had seen a forest floor carpeted with mushrooms of many kinds. She knelt before them, called them by endearing Russian names, and over my protests insisted on gathering them in her dress and taking them back to our lodge, where she went so far as to cook them and eat them - alone. My wife adored mushrooms, though she had never studied them or possessed a book about them. What she knew about them she had picked up at her mother's knee. The Great Russians experience a love for mushrooms that passes belief, that borders on the abnormal, just as we Anglo-Saxons are abnormally afraid of them.

This episode made so deep an impression on us that from then on, as circumstances permitted, we gathered all the information that we could about the attitude of various peoples toward mushrooms - what kinds they know, their names for them, the etymology of those names, the folklore and legends in which mushrooms figure, references to them in proverbs and literature and mythology. We were interested in what untutored folk knew about mushrooms, those who had never seen a book on the subject, but knew only what had come down by oral tradition from their ancestors. Like stout Cortez, awed by the spectacle of the Pacific from his peak in Darien, we found we were privileged to tread a virgin field ripe for exploration. Slowly it dawned on us that the peoples of Europe were divided ethnomycologically into two groups, those who adored mushrooms and those who had an exaggerated fear of them and loathed them - the "mycophiles" and the "mycophobes," words that we coined. The objective evidence supporting this hypothesis was reenforced by myriad clues to be found in philology and folklore. A bold surmise gradually gripped us: perhaps our remote ancestors had worshipped the mushroom. This would explain our evidence, for that which is worshipped is both adored and feared, both holy and unclean. We traveled far and wide, to Lapland, to the Basque country, to Friesland, until we had assembled what seemed to us an impressive body of clues. Like the long slow swell that rocks the ocean days after the mighty hurricane has passed, so our cold, fossilized evidence, for all its scholarly inertness, seemed to us to betoken, when assembled for the first time and properly read, the terror and adoration that had once gripped our primitive ancestors long ago, perhaps before history began. We postulated the cult of a divine mushroom, as astronomers postulate the presence of an astral body without having seen it, deducing its presence from the behavior of other bodies. The question remained: if mushrooms were worshipped, which mushrooms and why?

We now cast our net further afield and, in our inquiries, embraced all of the Eurasian land mass. What was our surprise and delight to discover that there are peoples in Siberia who have worshipped a certain kind of mushroom horn antiquity to our own time. They are the most primitive tribes in that primitive country, the Paleo-Siberian communities. We found that the use of mushrooms for ritualistic purposes was known in New Guinea, in Borneo. Then we went to Mexico, on our very doorstep. I have told you about our work there.

Perhaps we were helped, rather then hindered, by our lack of training in any of the disciplines that we needed. An academic scholar or scientist would have hesitated to tread where we wandered freely. In the course of our journeyings, both intellectual and geographical, we drew on the specialized knowledge of hundreds of informants, ranging from untutored country folk to academicians. In a sense my wife and I felt that we were merely the lens through which the light of their information was focused on the screen of our design. If the theories that we advance have any validity, the credit goes primarily to our informants. We wish we could cite all of them here. We wish we could cite at least all of the principal ones, men such as Robert Graves of Majorca, Spain; Adriaan Barnouw of New York, N. Y., Richard Schultes of Harvard University, Cambridge, Mass., and Gordon Ekholm of the American Museum of Natural History, New York, N.Y. There are, however, two men we shall cite to whom we owe a debt that we can never repay, without whose help we would never have brought our book to term.

First, there is that prodigious scholar and teacher, Roman Jakobson, of Harvard University and the Massachusetts Institute of Technology Cambridge, Mass, From the day we met him during World War II, he has encouraged us, he has pursued us relentlessly, plied us with rich material, with ideas, with questions, never letting us slow up, driving us on to get out our book. Preeminent as a Slavicist, as a philologist, as a linguist, as a folklorist, as a cultural historian, as a pioneer in the new science of communications, himself fertile in all these fields, electrifying as a teacher, he is truly one of the great intellects of our time, and withal abounding in those human qualities that endear him to his students and disciples. It has been our pride that we gained his friendship and captured his interest in our researches.

Then there is Roger Heim. We met him for the first time in 1949 in Paris, when we intruded into his presence in his laboratory, wholly unknown to him, without academic qualifications, without introduction except for a telephone call from a colleague who himself did not know us. From the beginning he has been our ever-loyal, ever-patient guide in all matters mycological. I need not say how difficult a scientific discipline his is. His dedication to it is entire, his knowledge of it encyclopedic. Beyond the horizons of mycology, he commands in an astonishing way the realms of general science and the humanities. In fact, for him all science is only an extension of the humanities, a frontier that men are now exploring and that they are incorporating into the ever-accumulating body of human knowledge and human culture. Editor of the *Revue de Mycologie*, Director of the *Laboratoire de Cryptogemie*, author of *Les Chempignons d'Europe*, a mushroom manual of new conception that surpasses anything we have in the English language, Director of the *Muséum National d'Histoire Naturelle*, *Membre de l'Institut*, occupying the very chair and the very room that Buffon occupied, an accomplished stylist in the French language, he exemplifies the finest traditions of French science and French culture. Without his ever-ready hand to help us over the hard places, without his authoritative voice to support us in our field work, we should never have dared to persevere. I am honored to have the privilege of paying this tribute to a great Frenchman, a great scientist, an eminent exponent of the best in the Western tradition of humane and scientific letters.

Use by the Huicholes of Jalisco
Present use in the United States
The peyote society
Among the Omaha Indians
Use in ancient Mexico
Summary

> **So-called "Sacred Mushroom," or Teonanacatl, Still in Use by the Indians of Mexico and the United States, Producing Hallucinations of a Remarkable Nature, Is Identified with the Peyotl Zacatecensis, or Devil's Root of Ancient Mexico, and the "Mescal Button" of Texas.**[1]

Accounts of many early travellers in America and missionaries to the Indians call attention to the veneration of the aborigines for various plants, showing that they attributed to all plants a spirit somewhat like that of animals or even of man himself. To certain plants special honors were paid; others were avoided with dread; while others, with no pronounced virtues or evil properties, were little noticed. An example is given by a Mexican writer of the homage paid to a certain tree cut down in order to form a bridge over a stream in Michoacan. The people of the village were called together by the governor and a religious service was held about a cross erected for the special ceremony, with candles burning before it and choristers assisting. A procession was formed which climbed the mountain, where the tree was growing. When it fell there came an aged Indian woman who, taking a few of its branches, laid them on the trunk where it had been cut, and consoling it with loving words begged that it might not feel humiliated or angry; for they had chosen it on account of its magnificent stature and great strength, and it was destined to span a mighty river, so that all the people of the land of Michoacan might cross over upon it. And before dragging it away they placed upon the place where it had fallen a piece of lighted candle, which had been left over from Holy Thursday; and they repeated in its honor a very solemn litany, sprinkling it with holy water and much pulque.[2] On the next day, having propitiated the spirit of the tree, they bore away the hewn beam to the bridge with much shouting and jubilation.[3]

The same author speaks of the veneration paid by the Mexicans to certain medicinal plants and to the narcotics *Ololiuhqui*, the sacred *Nanacatl*, the *Peyotl*, and the *Picietl* (tobacco), "to which they ascribe deity and with which they practice superstitions."

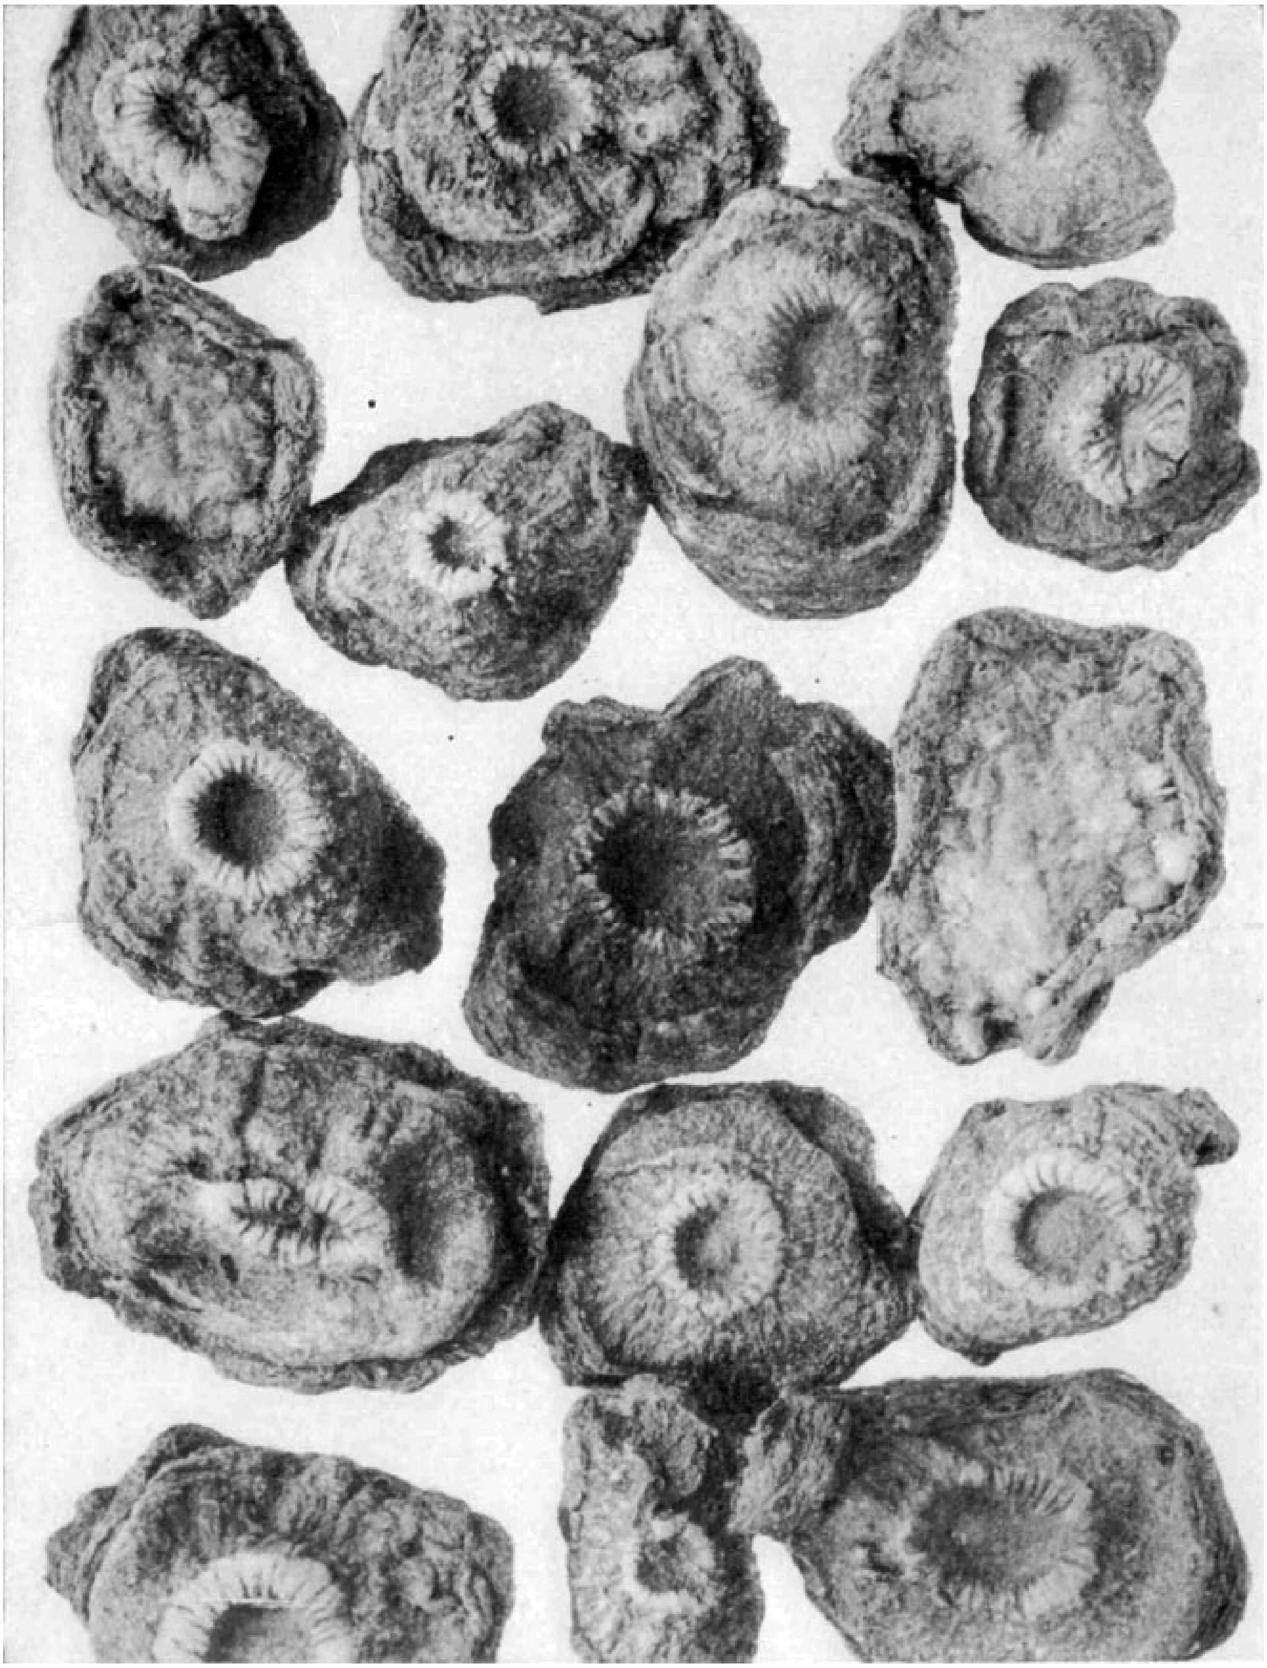

Fig. 1 - THE AZTEC NARCOTIC CACTUS, TEONANACATL
"God's Flesh," or "Sacred Mushroom" of the Aztecs - discs cut from the crown of the cactus *Lophophora williamsii* and dried. Photograph of specimens received by the Bureau of Chemistry, U. S. Department of Agriculture from the Indian Office in 1914. Now widely used as a narcotic by Indians on United States Reservations. - Natural size.

Methods of exorcism

The following example is among those given to show the method of exorcism employed by the Aztec *titzitls*, or herb doctors. In this case the spirit of the Ololiuhqui, is addressed. "Come now, come hither, *Green Woman*, behold the green heat and the brown heat; remove thou the flaming or scarlet heat, the yellow heat, or by this token I send thee to the seven caves. And, I command thee, put it not off till tomorrow or another day; for sooner or later thou wilt be compelled to do it. Who is the god - the so powerful and superior one - who can destroy the work of thy hands? I command it, I, the prince of enchantment." Others using the Hueinacaztli ("great-ear"), Mecaxochitl ("cord-flower"), and Coanenepilli ("serpent's tongue"), repeat the following: "Come hither, thou, the yellow and ardent red one; come and expel the green pain, the brown pain, which now wishes to take away the life of the son of the gods!" And with the herb Atlinan ("water-weed"), "I invoke thee, my mother, thou of the precious waters! Who is the god or who the so powerful one that wishes to destroy and burn my enchantment? Ea! Come thou, sister of the Green Woman, whom I am about to go and leave in the seven caves, where the green pain, the brown pain, will hide itself. Go and rub with thy hands the entrails of the bewitched one, so that thou mayst prove thy power and fall not into disgrace!"

Early history of Teonanacatl

Bancroft, in referring to the narcotics used by the ancient Mexicans, mentions one, which was believed by the early Spaniards to be a fungus. In writing of their ceremonial feasts he says: "Among the ingredients used to make their drinks more intoxicating the most powerful was the *teonanacatl*, 'flesh of God,' a kind of mushroom which excited the passions and caused the partaker to see snakes and divers other visions."[4] This information was undoubtedly derived from accounts of the Spanish padres, one of whom, Bernardino Sahagun, writing before the year 1569, states that it was the Chichimeca Indians of the north who first discovered the properties and made use of these "evil mushrooms which intoxicate like wine.[5]

They were gathered in the territory now northern Mexico and southern Texas, preserved by drying, and carried southward. The inhabitants of the Valley of Mexico knew them only in their dry state. It is also very probable that the early writers who recorded their use had seen them only when dry and never knew then: as living plants. Francisco Hernandez, the physician sent by Philip II in 1570 to study the resources of Mexico, or New Spain, describes them under the heading "*De nanacatl seu Fungorum genere*." From the harmless white mushrooms (*iztacnanacame*), red-mushrooms (*tlapalnanacame*), and yellow orbicular-mushrooms (*chimalnanacame*), used for food, he distinguished them as *teyhuinti*, which signifies "intoxicating."[6] In this connection it is interesting to note that this Nahuatl word, *teyhuinti*, or *teyuinti*, (from yuinti, to be drunk) survives, in the form of *tejuino* or *tehuino* in the State of Jalisco, Mexico, and *tesuino* or *tizwin* in the south-western United States, as the name of certain intoxicating drinks, the principal of which is a kind of beer brewed from malted maize.

Determination of the drug

Three centuries of investigation have failed to reveal an endemic fungus used as an intoxicant in Mexico, nor is such a fungus mentioned either in works on mycology or pharmacography; yet the belief prevails even now that there is a narcotic Mexican fungus, and it is supported by Simeon in his monumental dictionary of the Nahuatl language, in which the following definitions occur:

> "*Teonanacatl*, espèce de petit champignon qui a mauvais gout, enivre et cause des hallucinations; il est médicinal contre les fièvres et la goutte."[7]
>
> "*Teyuinti*, qui enivre quelqu'un, enivrant; *teyuinti nanacatl*, champignon enivrant."[8]

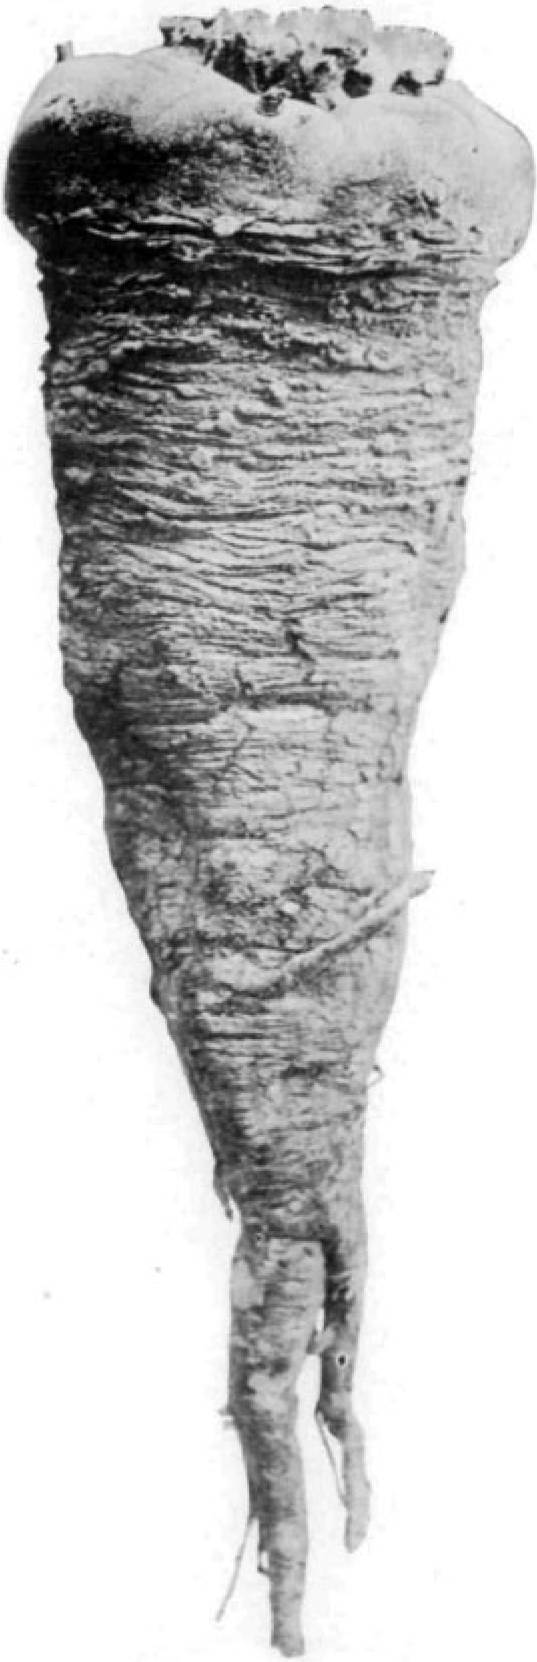

Fig. 2 - THE "DEVIL'S ROOT"
Peyotl Zacatecensis (*Lophophora williamsii*). "The root is of nearly medium size, sending forth no branches nor leaves above ground, but with a certain wooliness adhering to it. [On account of its magic properties] this root scarcely issues forth, but conceals itself in the ground, as though unwilling to harm those who may discover it and eat it." - Francisco Hernandez, 1576. Photograph natural size.

In connection with his study of the economic plants of the Mexicans and the Indians of the south-western United States the writer has sought diligently for a fungus having the properties attributed to the *teonanacatl*. As this narcotic was used by various tribes of *Chichimecas*, and the Chichimecas inhabited the territory situated in what is now northern Mexico and the southwestern United States, it was natural to look for the plant in this region. No such fungus, however, was discovered, but in its place a narcotic plant having properties exactly like those attributed to the *teonanacatl* was encountered; moreover, one form of this plant, when prepared as a drug, resembles a dried mushroom so remarkably that at first glance it will even deceive a trained mycologist. It is discoid in form and apparently peltate when seen from below; but the upper surface bears tufts of silky hairs, and a close inspection reveals the fact that it is the crown of a small fleshy spineless cactus which has been cut off and dried. The cactus in question, *Lophophora williamsii*, when entire, resembles a carrot or radish rather than a mushroom, and when cut into longitudinal slices or irregular pieces, would never be mistaken for a fungus. For this reason the drug prepared in the latter form was not recognized in southern Mexico as the same as the discoid form, and it was called *peyotl* by the Aztecs, while the name *nanacatl* was applied to the latter.

Identity with the narcotic peyotl

Sahagun, who described the drugs of the ancient Mexicans from specimens brought to him by Indian herb doctors, failed to recognize the identity of the *teonanacatl* and *peyotl* of the Chichimecas, although he attributes similar narcotic properties to each. The latter he describes as follows:

> "There is another herb, like tunas[9] of the earth; it is called *peiotl*; it is white; it is produced in the north country; those who eat or drink it see visions either frightful or laughable; this intoxication lasts two or three days and then ceases; it is a common food of the Chichimecas, for it sustains them and gives them courage to fight and not feel fear nor hunger nor thirst; and they say that it protects them from all danger."[10]

The plant itself was described by Hernandez as follows, under the heading *De Peyotl Zacatecensi, seu radice molli et lanuginosa*.

> "The root is of nearly medium size, sending forth no branches nor leaves above ground, but with a certain woolliness adhering to it on account of which it could not be aptly figured by me. Both men and women are said to be harmed by it. It appears to be of a sweetish taste and moderately hot. Ground up and applied to painful joints it is said to give relief. Wonderful properties are attributed to this root (if any faith can be given to what is commonly said among them on this point). It causes those devouring it to be able to foresee and to predict things; such, for instance, as whether on the following day the enemy will make an attack upon them; or whether the weather will continue favorable; or to discern who has stolen from them some utensil or anything else; and other things of like nature which the Chichimecas really believe they have found out. On which account this root scarcely issues forth, but conceals itself in the ground, as if it did not wish to harm those who discover it and eat it."[11]

From the above description, which applies perfectly to the plant from Zacatecas shown in fig, 2, it follows that the *Peyotl zacatecensis* of Hernandez is identical with *Lophophora williamsii*. Specimens of the drug collected at Zacatecas by the late Dr. Edward Palmer are shown in Fig. 3. They bear little resemblance to the mushroom-like buttons shown in Fig. 1, and it is not surprising that they should have been supposed to be distinct from the *teonanacatl* by the early Spanish writers.

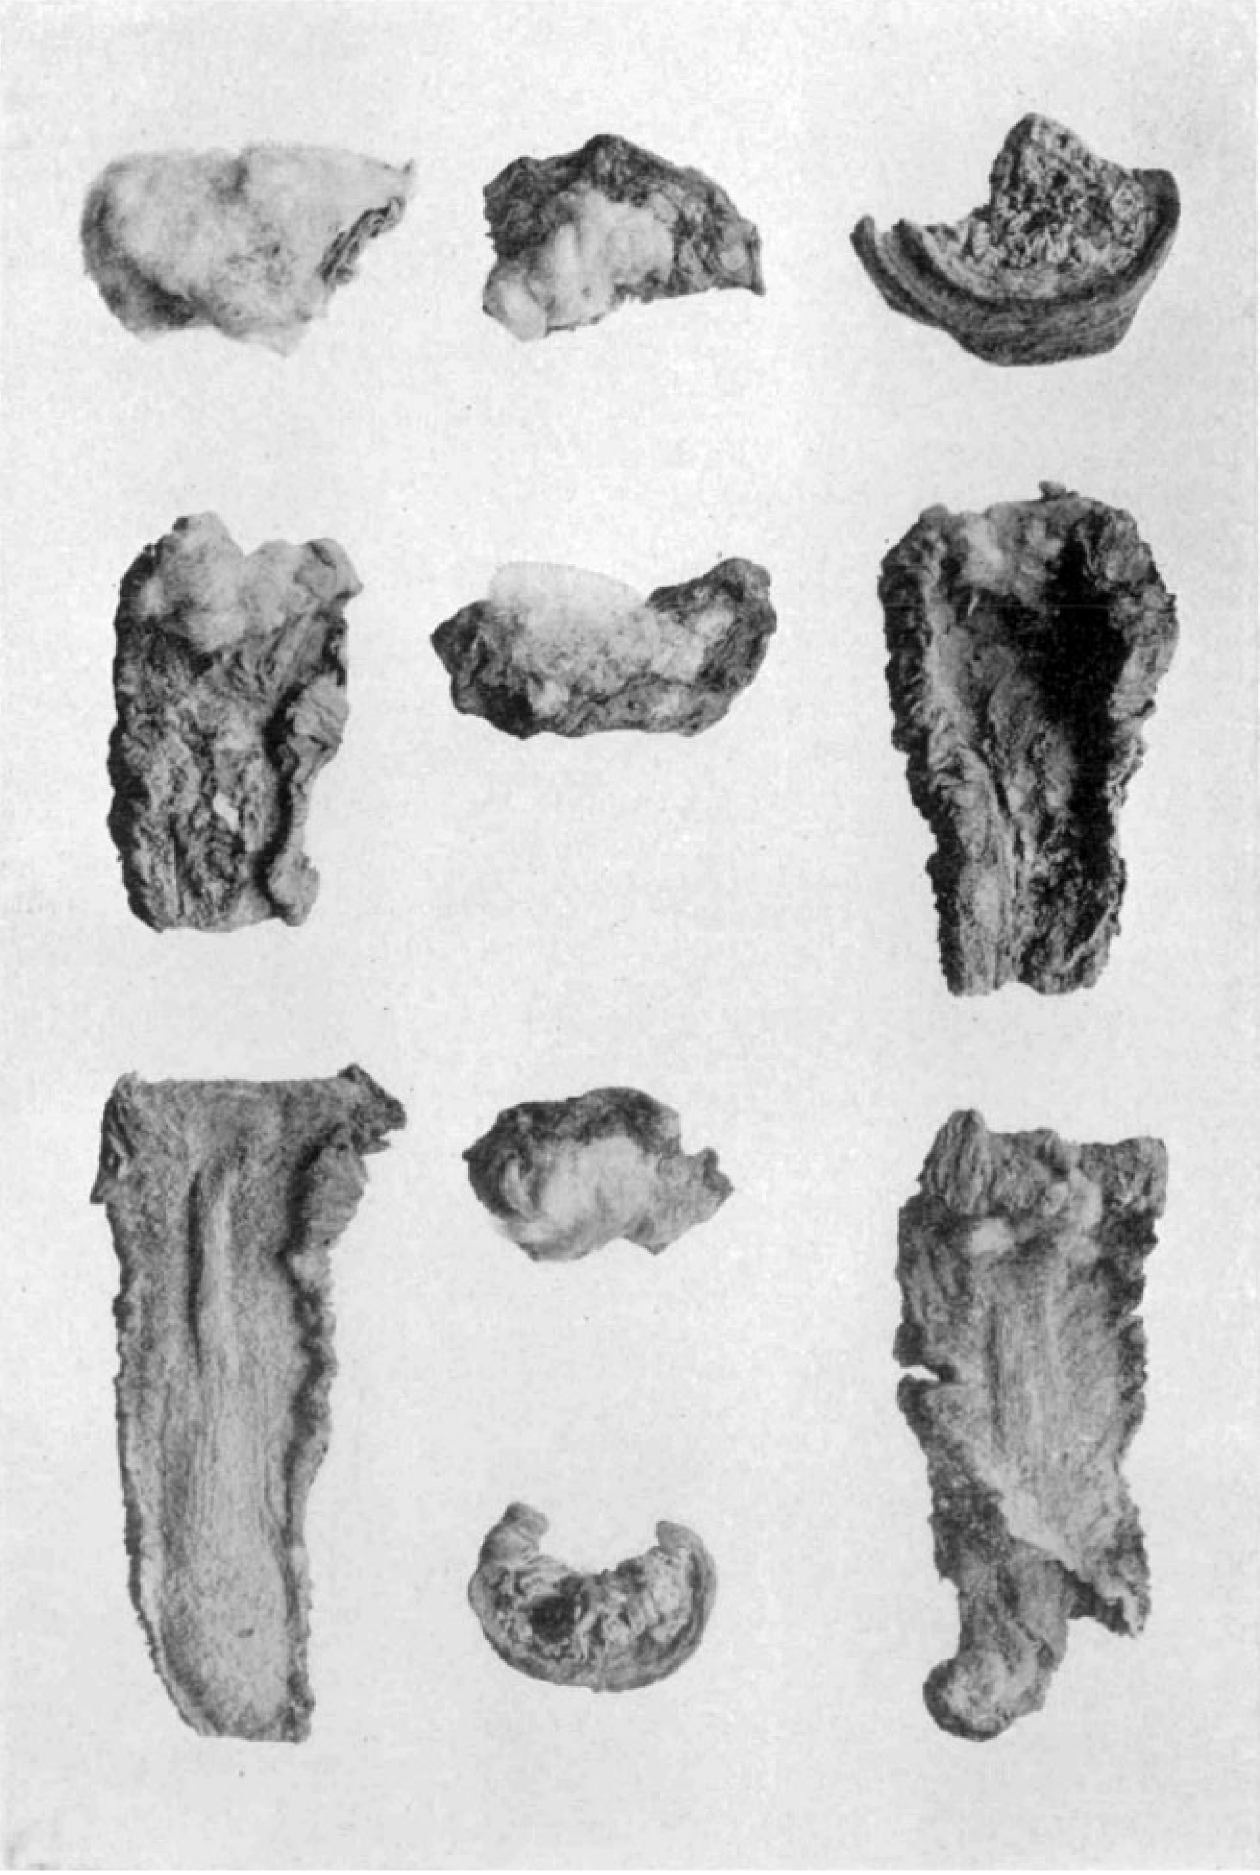

Fig. 3 - PEYOTE OF ZACATECAS, *Lophophora willamsii*
This form of the narcotic drug was called by the early Spanish missionaries "Raiz diabolica," or Devil's Root. Photograph of material in the Economic Collection, U. S. Department of Agriculture, collected at Zacatecas, Mexico, by the late Edward Palmer.

Raiz diabolica, or devil's root

By this name it was designated by Padre Jose Ortega, who tells of its use by the Cora Indians in his Historia del Nayarit, published anonymously at Barcelona in 1754, and republished under his own name in 1887. In describing their nocturnal dances he writes as follows:

> Close to the musician was seated the leader of the singing whose business it was to mark the time. Each of these had his assistants to take his place when he should become fatigued. Nearby was placed a tray filled with peyote which is a diabolical root (*raiz diabolica*) that is ground up and drunk by them so that they may not become weakened by the exhausting effects of so long a function, which they began by forming as large a circle of men and women as could occupy the space of ground that had been swept off for this purpose. One after the other went dancing in a ring or marking time with their feet, keeping in the middle the musician and the choir-master whom they invited, and singing in the same unmusical tune (*el mismo descompasado tono*) that he set them. They would dance all night, from 5 o'clock in the evening to 7 o'clock in the morning, without stopping nor leaving the circle. When the dance was ended all stood who could hold themselves on their feet; for the majority from the *peyote* and the wine which they drank were unable to utilize their legs to hold themselves upright."[12]

The early missionaries were opposed to the drug not so much on account of its physiological effects upon the Indians but because of its connection with certain superstitious rites connected with their primitive religion. Eating the *teonanacatl*, or *peyotl*, was declared by the padres to be almost as grave a sin as eating human flesh. In a little religious manual published by Fray Bartholomé Garcia in 1760, for the use of the missionaries to the Indians of San Antonio, Texas, the following questions, to be used in the confessional, are printed:

> "Has comido carne de gente?" (Hast thou eaten flesh of man?)
>
> "Has comido el peyote?" (Hast eaten the peyote?)[13]

The name *teonanacatl* is now obsolete. The drug is called by various names among the Indians using it: *xicori* by the Huicholes of Jalisco; *hikori*, or *hikuli*, by the Tarahumaris of Chihuahua; *huatari* by the Cora Indians of the Tepic mountains; *kamaba* by the Tepehuanes of Durango; *ho* by the Mescalero Apaches of New Mexico, who formerly ranged as far south as Coahuila; *seni* by the Kiowas; and *wokowi* by the Comanches, some of whom formerly lived in the state of Chihuahua. The name *peyote* has survived as a general commercial term; and the mushroom-like discs from the Rio Grande region are now widely spread among the northern Indians of the United States under the misleading names of "mescal buttons" or "mescal beans," as well as under the Nahuatl name *peyote*.

This name is of Aztec origin, derived from *peyotl*, the Nahuatl word for "cocoon." That its application to Lophophora was not general in early times is shown by the fact that Dr. Leonardo Oliva, professor of Pharmacology at the University of Guadalajara, declared it a singular thing that the *peyote* was regarded by the Mexicans as a plant having the virtue of giving unusual endurance to those using it, and the power of walking great distances without tiring. The only plant known to him by this name was a yellow-flowered Composite, with velvety tuberous roots, which from their form and indument might easily be likened to the cocoon of a moth.[14] As a matter of fact this name is still commonly applied to several species of Cacalia, the principal one of which, *Cacalia cordifolia*, is common in the vicinity of Guadalajara, Jalisco, in the drug markets of which the root is offered for sale under the name *peyote*.

Cacalia also called peyotl

The genus Cacalia belongs to the section Senecioneae, which includes Arnica, Tussilago, and other medicinal plants. To this genus should be referred the *Peyotl xochimilcensis* and the *Nanacace* of Hernandez, both of which are composites endemic in the neighborhood of Xochimilco, in the valley of Mexico, having a single stem growing from the middle of a cluster of nut-like tubers, with a terminal cluster of yellow-flowered rayless heads subtended by a scarious involucre. They should not be confused with the narcotic cactus called peyotl or peyote.

The peyote of Guadalajara, *Cacalia cordifolia*, was first described botanically by Kunth from specimens collected by Humboldt and Bonpland at Santa Rosa, Mexico. Its tubers, about the size of walnuts or hickory nuts, are covered with soft woolly hairs. From the center one of the cluster rises a single smooth terete stem bearing alternate, thickish, conspicuously net-veined leaves. The lower leaves are long-petioled, the upper ones, near the terminal inflorescence, are short-stemmed and much, smaller. The blades are roundish or broadly ovate, cordate at the base and angled on the margin. The flower heads are arranged in the form of a corymb, with many tubular 5-toothed flowers crowded on a naked flat receptacle, subtended by an involucre cupshaped in form, composed of many narrow acute teeth. There are no marginal ray-flowers. The disc-flowers have both stamens and pistils, the latter with an exserted forked stigma. The pappus is pilose, somewhat resembling thistledown when mature.

Fig. 4 shows the woolly tubers, reticulate leaves, and mature inflorescense of *Cacalia cordifolia*, photographed from material in the United States National Herbarium, collected by the writer in February, 1907, in the vicinity of Guadalajara, state of Jalisco, Mexico.

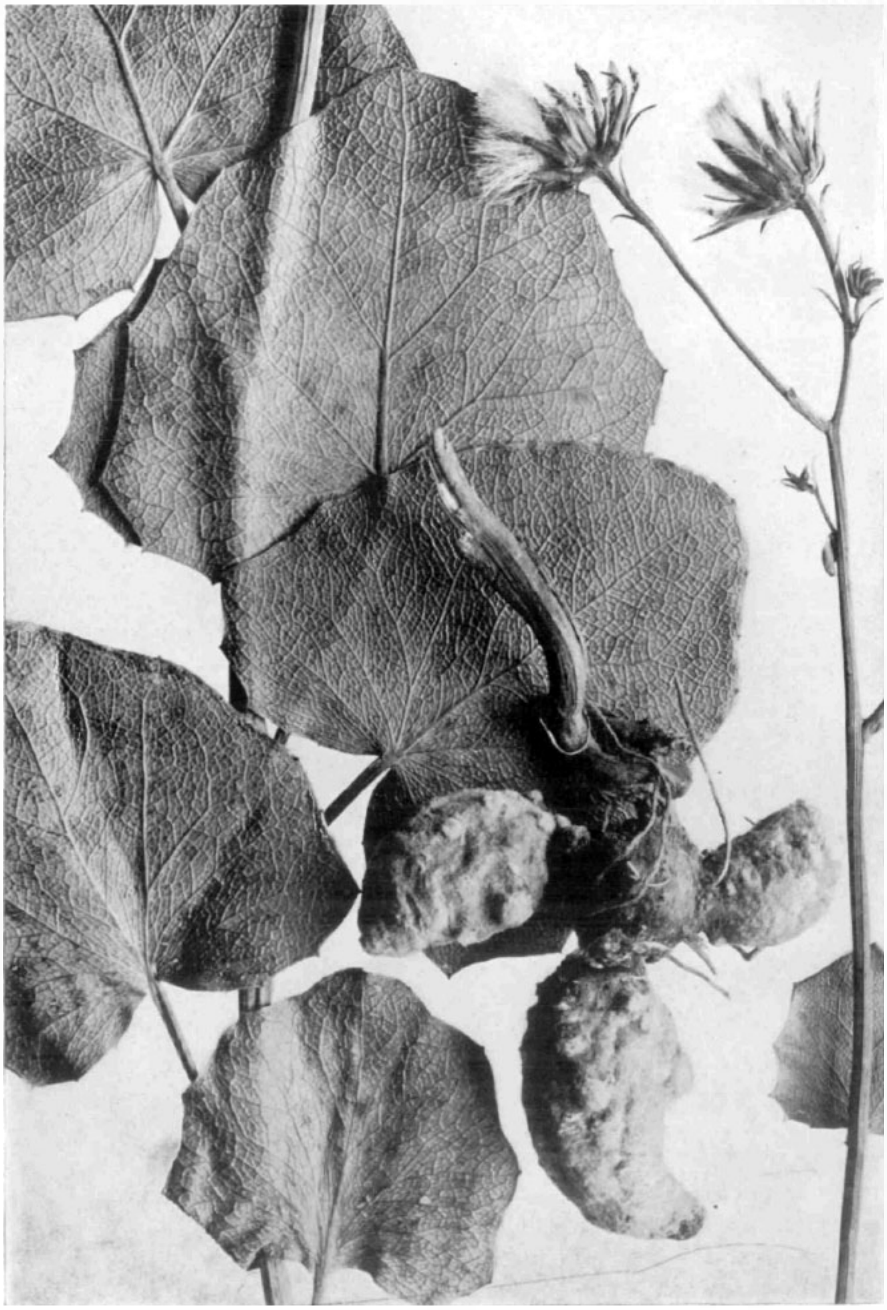

Fig. 4 - PEYOTE OF JALISCO, *Cacalia cordifolia*, **H. B. K.**
A member of the Composite, or daisy family, bearing velvety tubers; closely allied to the *Peyotl Xochimilcensis* of Hernandez. The tubers, called peyotl ("cocoons"), have medicinal properties, but they are not narcotic. Photograph of specimen in the U. S. National Herbarium collected near Guadalajara in 1907 by W. E. Safford. Photograph natural size.

Other specimens in the herbarium are from the Pedregal, or lavabeds, near Tlalpan, in the Federal District of Mexico, corresponding very closely with the descriptions of *Peyotl xochimilcensis*: of Hernandez; and from Alvarez, state of San Luis Potosi, where the tubers, locally known as *cachan*; are offered for sale in the drug-markets as an aphrodisiac and a remedy for sterility.

The genus lophophora

The genus Lophophora was based by Coulter upon a small plant described in 1845 by Lemaire, in the Allgemeine Garten-Zeitung, under the name *Echinocactus williamsii*. This plant, though suggesting certain echinocacti by its form differs essentially from all species of that genus in its fruit, which is devoid of scales, and resembles the smooth club-shaped "chilitos" of the Mamillarias. The plant is also devoid of spine-bearing areoles. In 1886 it was referred to the genus Anhalonium, which it resembles in its flowers and fruits,, but from the type of which it differs in several important features.

The genus Anhalonium, defined by Lemaire in 1839, proved to be identical with the genus. Ariocarpus previously established by Scheidweiler, the type of which, *Ariocarpus retusus*, described in 1838, is specifically identical with, the plant described the following year by Lemaire as *Anhalonium prismaticum*.[15] This fact was recognized in 1845, by Salm-Dyck, who, however, adopted the generic name *Anhalonium*.[16] On account of the laws of priority the generic name Ariocarpus must be retained and its synonym Anhalonium be dropped.

In the genus Ariocarpus (Anhalonium) the tubercles are very prominent, usually more or' less triangular or pyramidal in shape, and imbricating somewhat like the scales of an artichoke. The lower and upper parts are very different, the former comparatively thin and flat, while the upper exposed triangular part is very thick and hard. The lower surface of the tubercles is smooth and keeled, the upper surface is plane, as in *Ariocarpus retusus*; or convex and irregularly mamillate, with the acuminate apex bearing a woolly pulvillus, as in *Ariocarpus furfuraceus*; or more or less fissured and presenting a warty appearance, as in *Ariocarpus fissuratus*. One of these species is figured by Lumholtz under the name of *hikorisunami*,[17] and it is said by him to be more powerful than the common *hikori sunami* (*Ariocarpus williamsii*), but he offers no evidence that it has narcotic properties. The Indians declare that if you wear this plant as an amulet the bears cannot harm you nor the deer run away from you. The latter superstition is also held in connection with the closely related *Ariocarpus kotschubeyanus*, commonly called" pezuña de venado," (Fig. 5) probably on account of the close resemblance of its tubercles to the hoof of a deer.

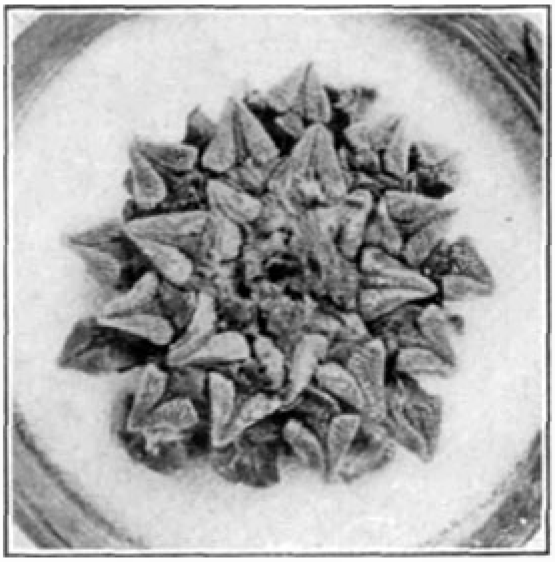

Fig. 5 - DEER-HOOF CACTUS
Ariocarpus kotschubeyanus, a plant with supposed magic properties, highly prized by Indians of northern Mexico, who declare that if the hunter wears this cactus (here shown natural size), the deer can not run away from him. It probably owes this prestige to the resemblance of its tubercles to the hoofs of a deer.

In the genus Lophophora the tubercles are quite unlike those of Ariocarpus (Anhalonium), being devoid of a differentiated upper part and having the lower part broad and rounded. Instead of being developed into pyramidal or triangular projections the tubercles often coalesce into broad continuous vertical or somewhat spiral ribs (Fig. 7), and in young specimens the plant appears almost smooth, with the tubercles separated by shallow impressed lines (Fig. 9).

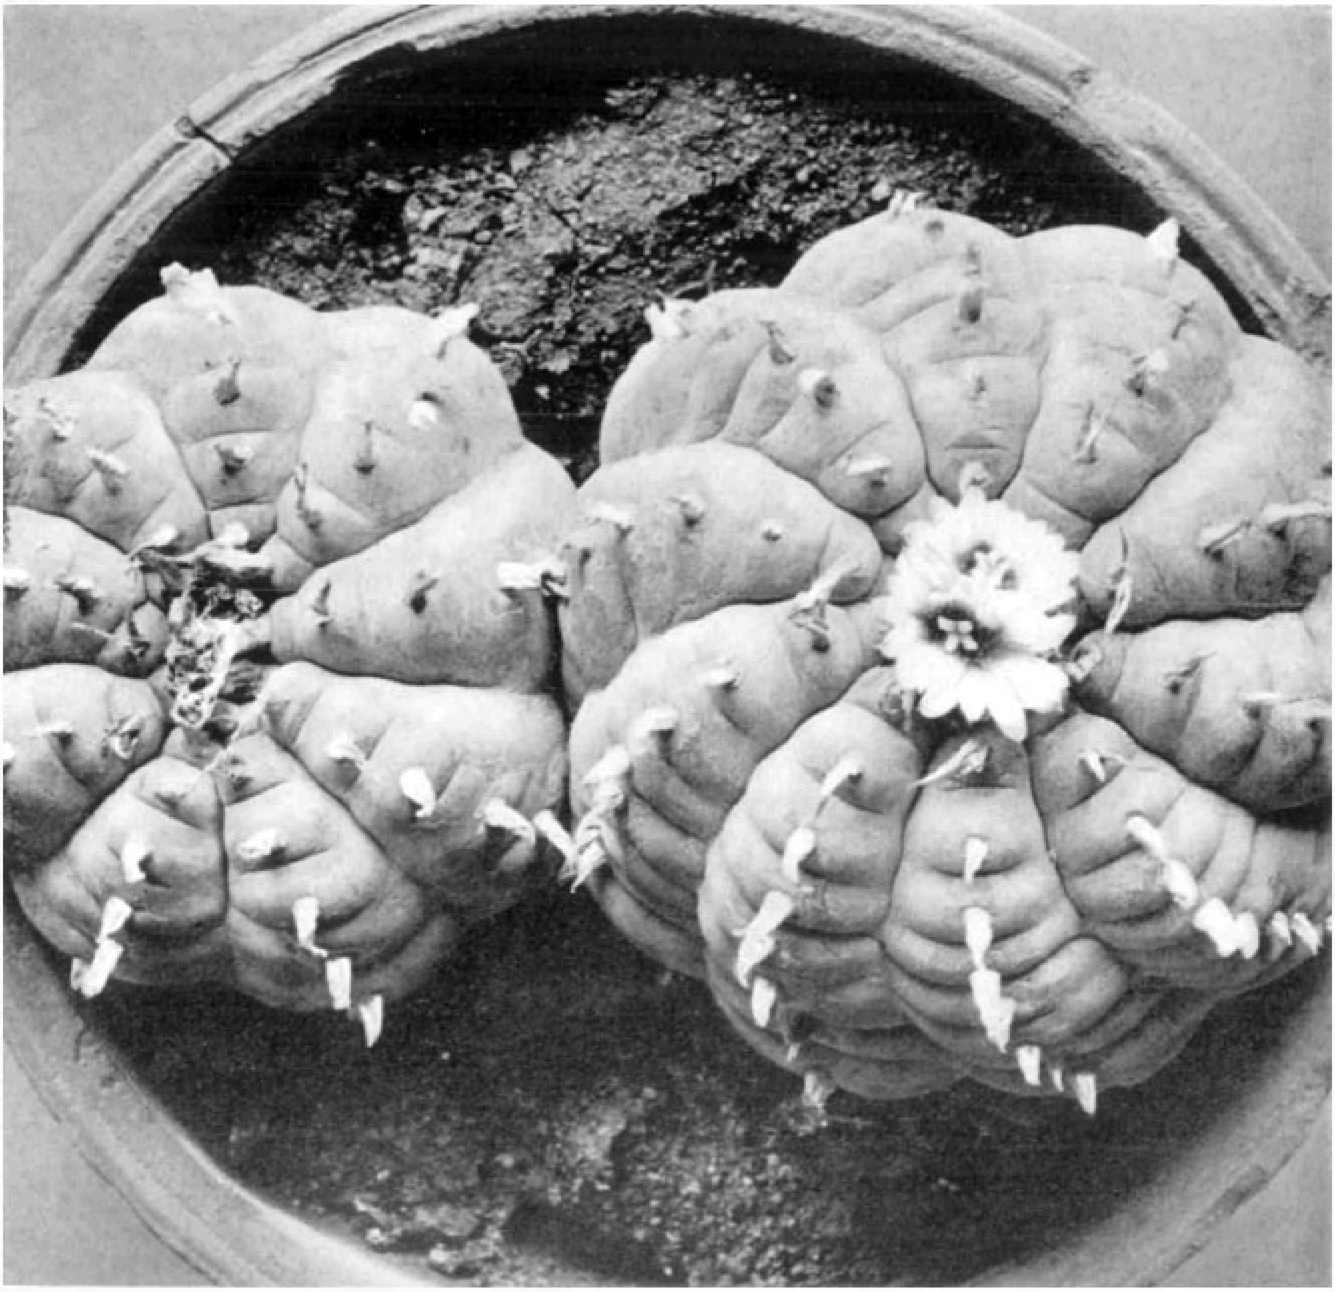

Fig. 7 - LOPHOPHORA WILLIAMSII
Typical form with defined ribs. Photograph of specimen in the Cactus House of the U. S. Department of Agriculture, collected in 1910, on the Hacienda de Cedros, near Mazapil, state of Zacatecas, Mexico, by Dr. Elswood Chaffey. Photograph natural size.

Lophophora williamsii

Lophophora williamsii (*Anhalonium williamsii* Lemaire) is a succulent spineless cactus, usually shaped like a turnip or carrot with a depressed-globose or hemispherical head bearing low inconspicuous tubercles and a tapering tap root. The tubercles occur normally in longitudinal ribs, but in some forms of the plant they are arranged spirally or irregularly. In the center of each tubercle there is a flower-bearing areole with a dense tuft of erect hairs, from the midst of which the flower issues. When mature the tuft of hairs persists as a pulvillus in the form of a pencil or brush of hairs. Unlike the plants of the genera Echinocactus and Mamillaria there is no spine-bearing areole. The flower (Fig. 6) is very much like that of an Ariocarpus, without a well-defined calyx, but with the outer floral leaves sepal-like and the inner ones petal-like and rose-tinted, with a darker median line on the back of each, giving to it a feather-like appearance. The stamens are numerous, with white filaments and bright yellow anthers: and the style bears four pale yellow stigmas projecting above the mass of stamens. The ovary is devoid of scales, in which respect it differs from that of the genus Echinocactus, and the smooth crimson or rose-colored club-shaped fruit resembles that of a Mamillaria. The plants grow either solitary, or, more frequently, in clusters of several from a common base.

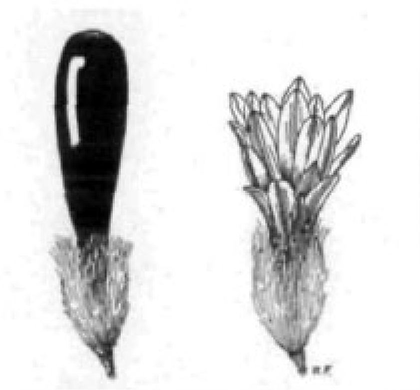

Fig. 6 - FRUIT AND FLOWER
Flower of *Lophophora williamsii* (at the right) with rose-tinted petals, issuing from a tuft of hairs, while the fruit (shown at the left) is pink or crimson. Drawing natural size.

Lophophora williamsii is quite variable, sometimes its ribs instead of being vertical are more or less diagonal or spiral, and instead of being separated by straight grooves the latter are sinuous; or the tubercles may be irregularly arranged. One form was described by Hennings as a distinct species under the name *Anhalonium lewinii*;[18] but the type plant described and figured by him was a boiled up "mescal-button" obtained from Parke, Davis & Co., of Detroit, Michigan, in all probability gathered in the vicinity of Laredo, Texas. In this form the ribs are usually thirteen in number separated by strongly sinuous grooves (Fig. 9). Sometimes there are twelve ribs or even as few as nine; while in the typical *L. williamsii* there are usually eight ribs separated by straight or almost straight lines, or sometimes as many as 10. It has been wrongly asserted that the petals of *L. lewinii* are yellow: typical plants of this form now blooming in the cactus house of the United States Department of Agriculture (May, 1915) have rose-tinted flowers in no way distinguishable in form or color from those of *L. williamsii*. Indeed, in specimens collected by Lloyd in Zacatecas typical plants of *L. williamsii* and *L. lewinii* are to be found in the same cluster growing from a common base. Another form (Fig. 10) departs from the typical *L. williamsii* even more than the plant figured by Hennings. It has the tubercles more or less irregularly arranged and separated into angular areas by intersecting lines. In young plants the surface is smooth, but in older plants (Fig. 8) the tubercles are often prominent. At first the writer was inclined to separate this form from both *L. williamsii* and *L. lewinii*, but after carefully comparing a number of specimens the three types seem to be connected by intermediate forms, and they cannot, therefore, be specifically distinct. Indeed as they sometimes grow from the same base it would be improper even to designate them as varieties.

Geographical distribution

The general range of the genus Lophophora is from southern Texas along the valley of the Rio Grande, from the mouth of the Pecos River south-eastward, to southern Querétaro, Mexico. Definite localities in which plants have been collected are the following:

Texas. - Mouth of the Pecos River, *William Lloyd*; vicinity of Laredo, *Mrs. Anna B. Nickels* (specimens now growing in the cactus house of the U. S. Department of Agriculture); near Ojuelos, *C. Ochoa* (dried specimens in the form of "mescal buttons" in the economic collection of the U.S. Department of Agriculture); near Aguilares (specimens sent by parcel post to the Menominee Indians, now in possession of the Bureau of Chemistry).

Tamaulipas. - In the vicinity of Nuevo Laredo, *Mrs. Anna B. Nickels*; near Camargo, south shore of the Rio Grande at the mouth of the Rio San Juan, *E. A. Goldman*, of the U. S. Biological Survey.

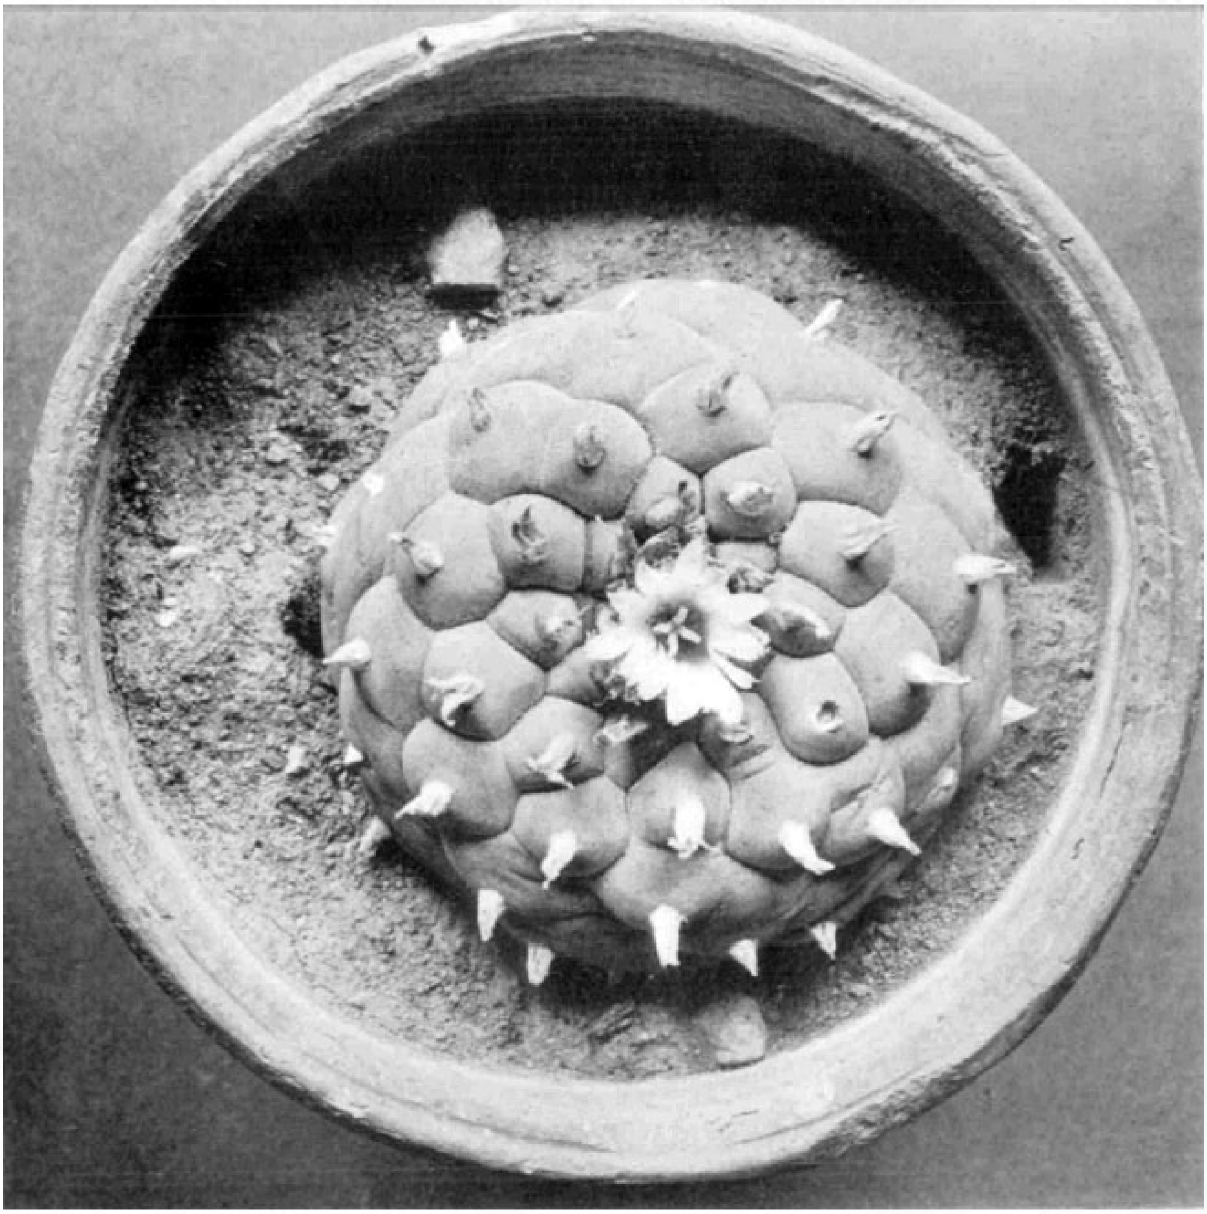

Fig. 8 - ANOTHER TYPE OF LOPHOPHORA
Form described by Hennings as a distinct species, *Anhalonium lewinii*, but often occurring in the same cluster with the typical form, growing from the same root. Photograph of specimen in the Cactus House of the U. S. Department of Agriculture, collected in the state of Zacatecas, Mexico, in 1908, by F. E. Lloyd. Photograph natural size.

Nuevo Leon. - Vicinity of Monterrey, *Professor Emilio Rodriguez*, (specimens growing in the cactus garden of the Colegio Civil, at Monterrey).[19]

Coahuila. - Cerro del Pueblo, near Saltillo, *Dr. Edward Palmer* (living plants in cactus house, U. S. Department of Agriculture; dried plants in economic collection).

Chihuahua. - Near Jimenez, in the Sierra de Amole (locality in which the Tarahumari Indians collect their supply for ceremonial purposes); near Santa Rosalía de Camargo, in the Sierra de Amargosa (also visited by the collecting expeditions of the Tarahumari Indians, as stated by Lumholtz).

San Luis Potosi. - Vicinity of Real de Catorce as cited by *Diguet* (locality whence the Huichol Indians obtain their supply).

Zacatecas. - Vicinity of Cedros, near Mazapil, near northern boundary, *Professor F. E. Lloyd* and *Dr. E. Chaffey* (living plants in the cactus house of the U. S. Department of Agriculture; also dried specimens from the market of the city of Zacatecas in the economic collection).

Querétaro. - Near Higuerillos, not far from the city of Querétaro, *Dr. J. N. Rose* (specimen in cactus house of the Department of Agriculture).

Chemical history of the drug

Attention was called to the use of this plant as an intoxicant by the Indians by Mrs. Anna B. Nickels of Laredo, Texas, who collected material for Parke, Davis and Co., of Detroit, Michigan, and for other wholesale dealers in drugs. Mrs. Nickels suggested that a chemical and therapeutic study of the plant be made, and stated that the plant was also used for "breaking fevers," and that the tops cut off and dried were locally known as " mescal buttons." The accompanying photograph of this veteran cactus-lover and assiduous collector, in her cactus garden at Laredo, was taken by David Griffiths of the U.S. Department of Agriculture.

A serious study of its properties was first begun in 1888, by Dr. L. Lewin of Berlin, who used for the purpose specimens obtained from Parke, Davis, and Company. It was afterwards studied by Dr. Arthur Heffter of the Pharmacological Institute of the University of Leipsic; and, in the United States, by a group of persons at Washington, centering in the Bureau of American Ethnology, and including as associates the Division of Chemistry of the Department of Agriculture for chemical analysis; Drs. D. W. Prentiss and Francis P. Morgan of the department of Materia Medica and Therapeutics of the Columbian University, for the study of its physiological properties; and the Botanical Division of the Department of Agriculture for the settlement of botanical questions. The material for the studies carried on in this country was supplied by James Mooney of the Bureau of American Ethnology. The chemical analysis was made by Ervin E. Ewell, who announced his results in a paper entitled "The Chemistry of the Cactaceae," read before the Washington Section of the American Chemical Society, April 9, 1896.[20]

Dr. Lewin obtained from the drug an alkaloidal substance which he called anhalonin. This substance was a brown, syrup-like liquid, having an intense alkaline reaction. From it Heffter obtained three alkaloids; the first, which he called anhalonin, was in the form of brilliant, colorless, needle-shaped crystals; the second was in the form of non-lustrous, white rhombic tables; the third was an amorphous and very poisonous alkaloid left behind by the mother liquor.

Mr. Ewell found, in addition to the alkaloids, at least two resinous bodies, and a wax-like substance insoluble in cold alcohol but soluble in hot alcohol, petroleum ether, and chloroform. The resinous bodies, of a dark brown color and thick consistency, have the characteristic taste and odor of the moistened drug itself. It was suggested that the drug's activity might be due to these resinous bodies rather than to the alkaloids. One marked peculiarity of the plant is that about one-half its ash proved to be potassium chloride - a proportion greater than that hitherto found in any other plant.[21]

Physiological action

Further investigations are about to be made in the Bureau of Chemistry by Dr. Lyman F. Kebler, chief of the division of drugs, and Dr. Francis P. Morgan, whose work in this drug has already been referred to.

The various accounts of the effects of Lophophora differ considerably; but nearly all of those who have experimented with it, including Dr. S. Weir Mitchell, agree in the statement that it produces beautiful color visions. The pupil becomes dilated and remains in this condition for some time, often for twenty-four hours, and at the same time there is a slight loss of the power of accommodation and consequent disturbance of vision. Depression of the muscular system has been observed as one of its effects, either well marked or indicated only by inactivity and lazy contentment; and sometimes this was followed by partial anesthesia of the skin after the effects of the drug began to disappear. Sometimes the patient was seized with nausea and vomiting, caused perhaps by the bitter and unpleasant taste of the drug when first put into the mouth. In some cases there was a marked loss of the sense of time. The effects of the drug have been compared with those of Indian hemp (*Cannabis indica*), which has found its way from the Eastern Hemisphere to Mexico and the southwest United States, where it is known as *marihuana*; but instead of the exciting effect of the latter, Lophophora produces rather a state of ideal content, with no tendency to commit acts of violence.

A detailed account of the experiments of Drs. Prentiss and Morgan was published in the Therapeutic Gazette of September 16, 1895, pp. 580-585.[22]

Ceremonial use by the Indians

The first to bring to public notice the ceremonial use of this narcotic by existing tribes of Indians was James Mooney of the Bureau of American Ethnology, in a paper read before the Anthropological Society of Washington on November 3, 1891. His attention had been directed to it while making investigations among the Kiowas, who are descendants of one of the tribes known to the Aztecs by the name of "Chichimecas." Mr. Mooney found that these Indians attribute divine powers to the drug and the ceremony attending its use is of the nature of a religious rite in which all the tribes of the southern plains take part.

The Kiowas and other Indians of Oklahoma receive the greater part of their supply of the drug from traders who bring it from the vicinity of Laredo, Texas, in the form of "mescal buttons," which are identical with the *teonanacatl* of the ancient Mexicans. Like the ancient Mexican feasts referred to above, their meetings are nocturnal, usually beginning Saturday night. A summary of Mr. Mooney's account was published in the Therapeutic Gazette of September 16, 1895. A more detailed description was published by Mr. Mooney the following January, in the same journal, from which the following extracts are taken.

"The ceremony occupies from twelve to fourteen hours, beginning about 9 or 10 o'clock and lasting until nearly noon the next day. Saturday night is now the time usually selected, in deference to the white man's idea of Sunday as a sacred day and a day of rest. The worshipers sit in a circle around the inside of the sacred tipi, with a fire blazing in the center. The exercises open with a prayer by the leader, who then hands each man four mescals, which he takes and eats in quick succession, first plucking out the small tuft of down from the center. In eating, the dry mescal is first chewed in the mouth, then rolled into a large pellet between the hands, and swallowed, the man rubbing his breast and the back of his neck at the same time to aid the descent. After this first round the leader takes the rattle, while his assistant takes the drum, and together they sing the first song four times, with full voices, at the same time beating the drum and shaking the rattle with all the strength of their arms. The drum and rattle are then handed to the next couple, and so the song goes on round and round the circle - with only a break for the baptismal ceremony at midnight, and another for the daylight ceremony - until perhaps 9 o'clock the next morning. Then the instruments are passed out of the tipi, the sacred foods are eaten, and the ceremony is at an end ... The dinner, which is given an hour or two after the ceremony, is always as elaborate a feast as the host can provide. The rest of the day is spent in gossiping, smoking, and singing the new songs, until it is time to return home."[23]

Among the Tarahumaris

Lumholtz, in his account of the plant-worship of the Tarahumari Indians of the southwestern Chihuahua, mentions several kinds of cacti which they regard with superstitious veneration; but there is no evidence that any of these have narcotic properties except the "hikori huanami," which is the typical *Lophophora williamsii*. A species of Ariocarpus (probably *A. fissuratus*) was sold to him under the name of "hikori sunami," and was declared by the vendor to have certain magical powers; but he did not see it used as an intoxicant. Much that Lumholtz relates in connection with the ceremonial use of the narcotic hikori appears extravagant and fanciful; but it is undoubtedly true that the Tarahumari Indians, like their more southerly neighbors the Coras and Huicholes, have been led by the wonderful visions induced by the plant to attribute to it supernatural powers. Even the Christians among them salute it and make the sign of the cross when approaching it, and it is often carried by them as a charm or amulet. They declare that Hikori sits next to God and is called "uncle," because it is God's brother.

It will be shown later that a similar superstition is common among some of the Indian tribes of the United States who pay to the plant divine homage. In some of their religious societies there is a ceremony of baptism in which the candidate is sprinkled with an extract of the plant, and also a kind of communion in which the plant is eaten as an incarnation of the Deity, or the flesh of God.

Lumholtz gives an account of the expeditions of the Tarahumaris in quest of hikori, describing their consecration with copal incense before starting out, their ten-days' journey to the land of the Hikori, the erection of a cross on their arrival, the superstitious observances attending the gathering of the plant, which recall the stories of the early European herbalists regarding the mandrake and other magic plants, and the ceremonies attending their return.

The Indians of the village go out with music to welcome the travellers, bearing their precious burden; and at night there is a festival of teswin-drinking and dancing in honor of the plant. The hikori is piled in a heap at the foot of a cross, and is sprinkled with teswin, which is grateful to it; and the next day a sheep or even an ox or two goats are sacrificed in its honor. The wild heathen Indians living in caves or under overhanging cliffs in the barrancas, when they hear of the return of the expedition, come to buy supplies of the hikori for their own use. "One plant," says Lumholtz, "costs a sheep, and the buyer holds a feast in honor of his purchase, and repeats the feast at the same time every year."[24]

Use by the Huicholes of Jalisco

The ceremonies attending the acquisition and use of the drug by the Indians of the Nayarit mountains of Jalisco and Tepic were described by Leon Diguet in 1899. These Indians belong to the tribes known as Huicholes, Coras, Tepehuanes, and Tepecanos. The Coras, whose use of the *raiz diabolica*, as described by Padre Ortega, has already been noted, now obtain their supply from the Huicholes. The latter send expeditions across the state of Zacatecas to Catorce in San Luis Potosi, where the plant is endemic. The specimens from Zacatecas in the Economic Collection of the Bureau of Plant Industry are not at all mushroom-like, but resemble dry pieces of radishes or carrots sliced longitudinally, or small, terminal fragments covered with silky wool, such as those . described by early writers as "*peyote de Zacatecas*." (See Fig. 3.) By the Huicholes the drug is known neither as peyote nor *teonanacatl*, but as *xicoli*, or *hicuri*, which is identical with the name *hikori* applied to it by the Tarahumari Indians.

According to Diguet the Huicholes collect the plant in October. The expedition lasts about one month, and its return is an occasion for celebration. "Those who take part decorate their hats and their hair with feathers and paint on their faces the distinctive attributes of their caste and of their gods. After having made an offering of peyote upon their altars they distribute pieces of it to all those they meet; a supply of peyote is kept for the feasts which will take place during the course of the year; the rest is sold to those who did not take part in the expedition.

"In eating the peyote the Indians chew the pulp of the plant, which has been cut up into small pieces, and at first spit out the saliva which at the beginning dissolves a bitter principle having a very disagreeable taste, then they absorb the active principle which dissolves little by little in the saliva."[25] According to Diguet the Indians regard the drug as food for the soul, and revere it on account of its miraculous properties. The manifestation of the hallucinations which it produces a little after the absorption of its active principle is held to be a supernatural grace by which men are permitted to communicate with the gods; and, moreover, "in using the drug with moderation the partaker is endowed with energy which permits him to overcome great fatigue and to endure hunger and thirst for five days."[26]

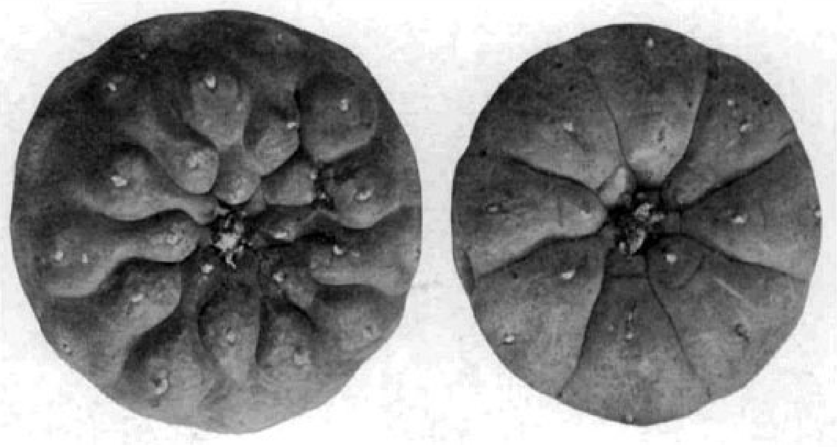

Fig. 9 - TEXAS TYPE
Specimens of Lophophora from the vicinity of Laredo, Texas; the upper one a typical *L. williamsii*, with eight ribs separated by straight grooves; the lower one identical with "*L. lewinii*," with 13 ribs seprated by sinuous grooves. Photographes from plants growing in Cactus House of U. S. Department of Agriculture; natural size.

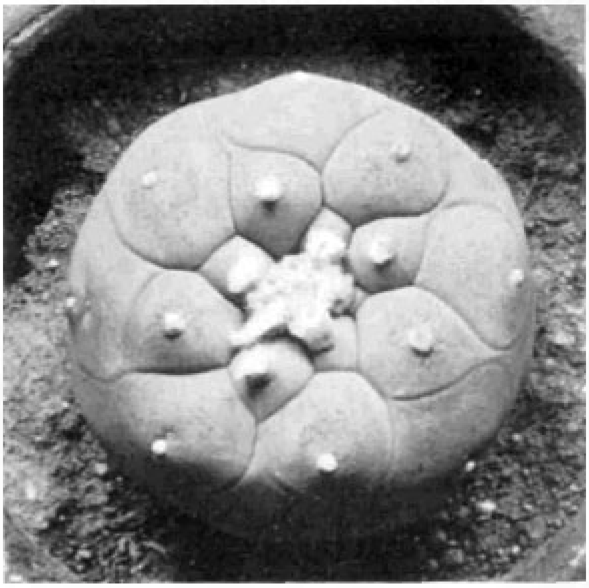

Fig. 10 - THE SOUTHERN TYPE
Young plant of Lophophora from Higuerillos, state of Queretaro, Mexico, the southern limit of the genus. Collected in 1905 by Dr. J. X. Rose. Photograph natural size.

Present use in the United States

Efforts have been made to prevent the spread of the drug among the Indians of the United States, and action has been taken in the courts to prosecute those who have been instrumental in procuring it and furnishing it. One of the most recent cases is that of the United States versus an Indian named Nah-qua-tah-tuck, alias Mitchell Neck, of the Menominee Indian Reservation. Wisconsin, accused of furnishing intoxicants to certain Indians, in violation of the law. Dr. Francis P. Morgan, of the Bureau of Chemistry, was summoned as a Government expert. The trial developed the following facts:

On March 15, 1914, the accused brought a supply of the drug in a dress suit case to the house of an Indian family named Ncconish, situated a short distance north of the village of Phlox, Wisconsin, near the western boundary of the Menominee Reservation, at which place there was a meeting of a religious nature. The drug had been received by parcel post from Aguilares, Texas. The participants first made a line about the house to keep out the evil spirits, and then invoked God, begging him to make all of them good and to keep them from evil. The peyote was next distributed, and when it was eaten caused the partakers to see the evil things they had done and showed them the good things they ought to do.

The ceremony began about 9 o'clock in the evening. One witness testified that shortly after having eaten four buttons he could see pictures of various kinds when his eyes were shut. First he saw God, with a bleeding wound in his side. This vision vanished when he opened his eyes, but reappeared when he closed them again. Then he saw the devil with horns and tail, of the color of a negro. Then he saw bad things which he had done before, bottles of whiskey which he had drunk, a watermelon which he had stolen, and so many other things that it would take all day to tell of them. Then he saw a cross with all kinds of colors about it, white, red, green and blue. He was not made helpless. He stated that he could have walked had he wished to do so, but that he preferred to sit still and look at the pictures.

Another witness testified that he ate the peyote so that his soul might go up to God. The witnesses who testified at this trial declared that the peyote helped them to lead better lives and to forsake alcoholic drinks. The defendent was acquitted on the ground that the meeting was one of a religious nature.

The peyote society

Thomas Prescott of Wittenberg, Wisconsin, testified that there is a regularly-organized association among the Indians called the Peyote Society, also known as the Union Church Society, of which he had been a priest for seven years. In the weekly ceremonies of this society the peyote is either eaten or taken in the form of tea. In his opinion the effect of the peyote is to make better men of the Indians. Many of them were formerly common vagabonds, liable to commit all sorts of crimes when under the influence of alcohol. After becoming members of the peyote society, however, they gave up drink, established themselves in regular homes, and lived sober and industrious lives. In relating his personal experience he made the following statements:

> "We boys, before we got this peyote, was regular drunkards; so when I was drunk I was lying on the road somewhere sometimes, and I got no home nor nothing. Before I got this I did wrong and everything else. Now, since I got this peyote, it stopped me from drinking, and now, since I used this peyote, I have been sober, and today I am sober yet ... I see a good and a bad when I eat that peyote. When I eat that peyote then it teaches me my heart; I know anything that is right and what is wrong. That is the way peyote works for good and works for God, and that is how we worship. ... When I took this peyote I could see myself when I used to be drunk; I could see the bottles which used to have my whiskey and alcohol in; I could see myself lying drunk in the road. That is the way it shows us the bad and teaches us the good. ... We could have our meetings without this peyote; but we see some more coming - a new person - he wants to use it - when he takes this peyote then he believes God. That is why we use it for. Without this, why, they would not believe anybody."[27]

Dr. Morgan gave to the court an account of his experiments bearing upon the physiological action of the drug administered in his presence to several young men who had volunteered for the purpose. The chief effect noticed was the production of visions of various kinds: of moving objects, constantly changing designs and figures of landscapes, friezes, balls of beautiful colors in constant motion. Suggestions of definite objects also brought up visions of that object. These visions were seen only when the eyes were closed. The pupil of the eye was made larger, and this enlargement lasted till the following day; the pulse became slower at first but increased when a greater quantity of the drug was taken; there was evidence of muscular depression with a disinclination to exertion of any kind; and there was a loss of conception of. space and time and, in some cases, symptoms of dual personality, not unlike that caused by hashish (*Cannabis indica*). The after effects, however, were insomnia, while hashish eating is usually followed by sleep. In this respect it also differs from opium and somewhat resembles the active principles of coffee and coca (*Erythroxylon coca*). Dr. Morgan further testified that as far as he knew no therapeutic or remedial value of the drug had been established.

At a meeting of the Lake Mohonk Conference in October, 1914, several papers relating to the effects of this drug upon the Indians were read and affidavits from two Omaha Indians were quoted. From one of the latter, I take the following extracts:

Among the Omaha Indians

At the meetings of the Society "before they sing they pass the peyote around. They begin taking this medicine along about dark, and when they pass it, ask you how many you want, and they often try to persuade you to take more than you want. The medicine does not work right away, but after it begins to take effect along toward midnight they begin to cry and sing and pray and stand and shake all over, and some of them just sit and stare. I used to sit in their range right along, and ate some of their medicine, but after I ate it the first time I was kind of afraid of it. It made me feel kind of dizzy and my heart was kind of thumping and I felt like crying. Some of-them told me that this was because of my sins. It makes me nervous, and when I shut my eyes I kind of see something like an image or visions, and when my eyes are open I can't see it so plain. One of these fellows took twelve beans, or twelve peyote, sitting with some girls ... After I have taken twelve peyote I saw a mountain with roads leading to the top and people dressed in white going up these roads. I got very dizzy and I began to see all kinds of colors, and arrows began to fly all around me. I began to perspire very freely. I asked to be taken out of doors. At that time it was 20° below zero. I felt better when I got out of doors. When I went in again I began to hear voices just like they came from all over the ceiling and I looked around in the other room and thought I heard women singing in there, but the women were not allowed to sing in the meetings usually, and so this was kind of strange. ... After eating thirty-six of these peyote I got just like drunk, only more so, and I felt kind of good, but more good than when I drink whiskey, and then after that I began to see a big bunch of snakes crawling all around in front of me, and it was a feeling like as if I was cold came over me. The treasurer of the Sacred Peyote Society ... was sitting near me, and I asked him if he heard young kittens. It sounded as if they were right close to me; and then I sat still for a long time and I saw a big black cat coming toward me, and I felt him just like a tiger walking up on my legs toward me, and when I felt his claws I jumped back and kind of made a sound as if I was afraid, and he asked me to tell him what was the matter, so I told him after a while. I did not care to tell at first; but I made up my mind then, after what I saw, that I would not take another one of these peyotes if they gave me a ten dollar bill. ... In this Sacred Peyote Society they have a form of baptism and they baptize with the tea made from stewing the peyote, and they baptize 'in the name of the Father, and the Son, and the Holy Ghost,' the Holy Ghost being the peyote. Then you drink some of the tea and they make signs on your forehead with the tea and then take an eagle's wing and fan you with it. I heard an educated Indian and he said in a meeting on Sunday morning, ' My friends, I am glad I can be here and worship this medicine with you; and we must organize a new church and have it run like the Mormon Church.'"[28]

Use in ancient Mexico

From the preceding description of a meeting of the Sacred Peyote Society held by the Winnebagos and Omahas in 1914 I turn back to the first account we have of the *Teonanacatl* feasts of the Aztecs, written by Padre Bernardino Sahagun in the sixteenth century - before Sir Francis Drake set out upon his voyage round the world - before tobacco which, under the name of *picietl*, the Mexicans also worshipped, was first brought to England

"The first thing eaten at the party was certain black mushrooms which they call *nanacatl*, which intoxicate and cause visions to be seen, and even provoke sensuousness. These they ate before the break of day, and they also drank cacao (chocolate) before dawn. The mushrooms they ate with syrup (of Maguey sap), and when they began to feel the effect they began to dance; some sang; others wept because they were already intoxicated by the mushrooms; and some did not wish to sing, but seated themselves in their rooms and remained there as though meditating. Some had visions that they were dying and shed tears; others imagined that some wild beast was devouring them; others that they were capturing prisoners in warfare; others that they were rich; others that they had many slaves; others that they had committed adultery and were to have their heads broken as a penalty; others that they had been guilty of a theft, for which they were to be executed; and many other visions were seen by them. After the intoxication of the mushrooms had passed off they conversed with one another about the visions which they had seen."[29]

The following description of a religious meeting in July, 1626, at which sacred mushrooms were administered in the form of communion, is related by Padre Jacinto de la Serna, at that time beneficiary of Tenantzingo.

"To this meeting had come an Indian, native of the pueblo of Tenango (about 25 kilometers from Toluca) and grand master of superstitions, named Juan Chichiton (or "John Little-dog"), who had brought some of the mushrooms that are gathered in the *monte*, and with these he had performed a great idolatry. But before proceeding with my story I wish to explain the nature of the said mushrooms, which in the Mexican language are called *Quauhtlananacatl* ("wild mushrooms"). When I asked the *licenciado* Don Pedro Ponce de Leon what they were like, he said that these mushrooms were small and yellow, and that they were collected by priests and old men, appointed as ministers for these impostures, who would proceed to the place where they grow and remain almost the whole night in prayer and in superstitious conjuring; and at dawn, when a certain little breeze known to them would begin to blow, then they would gather the narcotic, attributing to it deity, with the same properties as *ololiuhqui* or *peyote*, since when eaten or drunk, they intoxicate those who partake of them, depriving them of their senses, and making them believe a thousand absurdities."[30]

"This man, Juan Chichi ton, brought these mushrooms one night to a house where there was a gathering for the celebration of a saint's feast. The saint stood on the altar and below the altar were the mushrooms, with some pulque, and fire. All night long the *teponaztli* (wooden drum made from a hollowed log) kept time to the singing, and after the greater part of the night had passed, the said Juan Chichi ton, who was the priest of that solemnity, administered to all those congregated at the feast mushrooms and pulque after the manner of communion, winding up the celebration with an abundant quantity of pulque; so that the mushrooms on their part and the pulque on its, took away their reason, which was a pity. The said Juan Chichiton fled soon afterward, nor could I obtain information about the others who took part, in order to chastise them, with the exception of Leonor Maria, whom I kept as a prisoner in my house for having joined in the idolatry which they performed with the mushrooms."

Fig. 11 - MRS. ANNA B. NICKELS IN HER CACTUS GARDEN
This veteran cactus lover, a resident of Laredo, Texas, called attention to the narcotic properties of Lophophora, and supplied to Parke, Davis & Co. material with which to investigate the drug. Photograph by David Griffiths, U. S. Department of Agriculture.

"I asked the said *licenciado* Don Pedro Ponce de Leon in what manner these creatures perform their acts of witchcraft in working harm to others; and he told me that in making their threats and menaces they strike themselves on the breast as at the Sanctus with the tips of their fingers and then, opening their hand, they make a gesture as if hurling something in the direction of the person whom they are menacing or wish to bewitch, saying: 'You shall pay me for that, as you will see!' But concerning other words and things which they say and do by order of the devil in these *embustes*, never or scarcely ever could anything be ascertained; though it stands to reason that they must have them as a pact with the devil; and he, who is the author of all, closes their mouths, so that there may be no means of remedying the evil."[31]

Summary

After comparing the preceding accounts of the use of narcotics by the ancient Mexicans and by the Indians of the present day, separated in time by three centuries and in space by thousands of miles, there can remain no doubt that the mushroom-like peyote used by our own Indians in the United States, which we know to be identical with, the sacred *hikuli*, or *hicori*, of the Sierra Madre Indians, is the same drug which was called *teonanacatl*, or "sacred mushroom," by the Aztecs. According to the earliest writers, it was endemic in the land of the Chichimecas, the early home of our Apaches, Comanches, and Kiowas, which is also the source of the modern supply. The ancient Mexicans, like the Huicholes and Tarahumaris of the present day, obtained their supply of the drug through the medium of messengers, consecrated for the purpose, who observed certain religious rites in collecting it, and who were received with ceremonial honors on their return. Although the Indians on our northern reservations now receive it through the medium of the parcel post; yet they attribute to it the same divine properties as the ancient Mexicans and like them combine its worship with the religion they have received from Christian missionaries. It is only natural that those who arc engaged in the work of Christianizing and uplifting our Indians should try, like the early Spanish missionaries, to stamp out its use. On the other hand many of the Indians who use the narcotic declare that they take it as a kind of sacrament or communion, and that it helps them to turn from wickedness and lead good lives.

A knowledge of botany has been attributed to the Aztecs which they were far from possessing. Their plant names show that their classification of plants was not based upon real affinities, and it is very probable that they had not the slightest notion of the difference between a flowering plant and a fungus. Certainly they applied the names *nanacatl* and *nanacace* to both fungi and flowering plants and the name *peyotl* to both the narcotic cactus, Lophophora, and to the tuber-bearing composite, Cacalia. The botanical knowledge of the early Spanish writers, Sahagun, Hernandez, Ortega, and Jacinto de la Serna, was perhaps not much more extensive: their descriptions were so inadequate that even to the present day the chief narcotic of the Aztecs, *Ololiuhqui*, which they all mention, remains unidentified.[32] They knew these narcotic drugs only in their dry state; and the general appearance of the *peyotl* brought from the vicinity of Zacatecas (Fig. 3) was so very different from the *teonanacatl* from the more northerly region inhabited by the Chichimecas (Fig. 1) that the two forms might easily have been regarded as coming from distinct plants.

As far as the author knows, this is the first time that the identity of the "sacred mushroom" of the Aztecs with the narcotic cactus known botanically as *Lophophora williamsii* has been pointed out. That it should have been mistaken by the early Spaniards for a mushroom is not surprising when one notices the remarkable resemblance of the dried buttons to peltate fungi, and also bears in mind that the common potato (*Solanum tuberosum*) on its introduction into Europe was popularly regarded as a kind of truffle, a fact which is recorded by its German name, *Kartoffel*, or *Tartuffel*.

Lumholtz, Carl - Unknown Mexico 2: 126-136. 1902.
31. Jacintode la Serna, "Manual de los Ministros para el conocimiento de sus idolatrías y extirpacion de ellas," in Documentos inéditos para la Historia de España, vol. 104, p. 61. Madrid, 1892.
32. Sahagun describes two plants bearing the name *Ololiuhqui*: one, which is not narcotic, with a fleshy turnip-like root, leaves like those of a Physalis, and yellow flowers; the other, also called *Coaxoxouhqui*, or "green snake," with highly narcotic seeds. (Op. cit. vol. 3, pp. 264, 241.) Hernandez describes the latter as round like those of Coriander, and says that they are produced by a twining plant called *Coaxihuitl*, or "snake-weed," which has fibrous roots and longish white flowers (Hern. ed. Recchi, p. 145); while Serna does not describe the plant, which he probably never saw, but compares the form of the seeds to that of lentils: "semilla a modo de lantejas que llaman Ololiuhqui." (Op., cit. p. 163.) Hernandez thought the plant might be the same as the *Solanum maniacum* of Dioscoroides. Dr. Manuel Urbina, of the National Museum of Mexico, declared it to be *Ipomoea sidaefolia* of Choissy; but this identification, while agreeing with Hernandez's illustration, lacks confirmation through investigation of the chemical properties and physiological action of the seeds of this species; and it is not known that any of the Convolvulaceae are narcotic, though many of the Solanaceae, which have somewhat similar flowers, are highly so. It is very strange that Mexican botanists living in the country of the Ololiuhqui have not solved the mystery of its identity.

Celestial Botany: Entheogenic Traces in Islamic Mysticism

Abstract

This paper will highlight some of primary evidence for entheogenic plant use in Islamic cults that partake of a vastly older legacy of ritual plant use. The accumulated research on entheogens and religions demands that certain traditions be reevaluated in light a continuing and coherent symbolism that enshrines holy plants as high mysteries in diverse faiths. Following the *soma/haoma* complex through Asia and Chinese Shamanism and into Persian and Islamic cults the use of entheogens meets with traditions in the ancient Middle East that shared doctrines of magic plants and cup rituals of visionary wine. The Greek, Semitic and Hermetic traditions merge with the shamanic techniques that persist in the esoteric symbolism of the Shia Muslims and Sufi as demonstrated in their holy books, art and poetry. The alchemical tradition thus emerges has having a definite entheogenic context that was cherished and protected by initiates from the profane. This speculative hypothesis rests on the collective evidence of religious traditions surrounding Islam that possessed similar rituals and reverence for plants that becomes a hidden aspect of mystical Islam.

Keywords: Shia, Sufi, Soma, Hoama, entheogen, *Amanita muscaria*.

An Entheogenic Heritage

The world's oldest religions clearly have a heritage of entheogens at their ritual core. While the debates and speculations will no doubt continue as to precise species or preparation, the role of these plants and their extracts becomes more and more self-evident. The pioneering research of various scholars have made very persuasive arguments for sacramental plant use in various cultures from Vedic Brahmins (Wasson 1968; Houben 1999) to Greek mystery religions (Ruck 1992) and Christian mystics and Manicheans (Allegro 1970; Ruck, Heinrich and Staples 2000; Hoffman and Ruck 2007). Researchers have further focused their attentions on various myths, folklore and art to articulate the central and ancient role of "magical plants" from an Irish Soma (Wilson 1999) to Tantric Buddhist sects (Hajicek-Dobberstein 1995, Crowley 2005, Strickmann 1966). This extends to the heirs of these ancient religions in such traditions as Islam (Dannaway, Piper, and Webster 2006; Piper 2002) alchemy and Grail mythology (Heinrich 2002, Shelly 1995) and Freemasonry (Hoffman and Ruck 2002).

This paper will offer some additional evidence that would support a similar complex of plant use into various Islamic cults. The utterly ancient Epic of Gilgamesh must be cited as a precedent for such ideas, as it is a quest for a "plant of immortality" that spreads and inspires doctrine of similarly described soma/haoma plants found throughout the ancient world. Likewise, the Egyptians seem to have had various entheogenic wines or beers and plants at their disposal with some suggestions of various mushroom species (Berlant 2005). The works of Joseph Needham (1975), an early collaborator with Wasson, on China and its sciences becomes most revealing in the field of alchemy which will prove a link for these cultures across space and time. Here the older influences and precursors to the elaborate and increasingly esoteric world of elixir alchemy unite and disperse into the Persian and Islamic world ending in Europe, which may well have retained the entheogenic legacy (Ruck 2007). For it is in China that Vedic, Daoist, Buddhist, Tantric, and indigenous shamanism combine into a dynamic and yet esoteric doctrine that makes sense of the Prophet Muhammad's hadith to "seek knowledge, even unto China." This often took the form of metallurgical symbolism effused with mystical teachings that evolved into alchemy (Needham 1954, 1975; Giradot 1983; Kalyanaraman 2004). The word *Sufi* may itself be Chinese and intimately connected with Chinese Shamanism which preserved the ancient associations of magic plants (Needham 1954; Mahdihassan 1959, 1990).

Needham's insightful research distills some essentials about this complex of plants and metals that combine in the alchemical arts, which he associates with the *Amanita muscaria* mushroom and other entheogenic preparations. The earliest Chinese texts use the language of "searching for" (chhiu) the herb or plant of immortality (often described as a fungus) while later it came to be "effecting a chemical transformation" or "preparing by heating" which is startling to contemplate though the implications go far beyond the scope of this discussion.

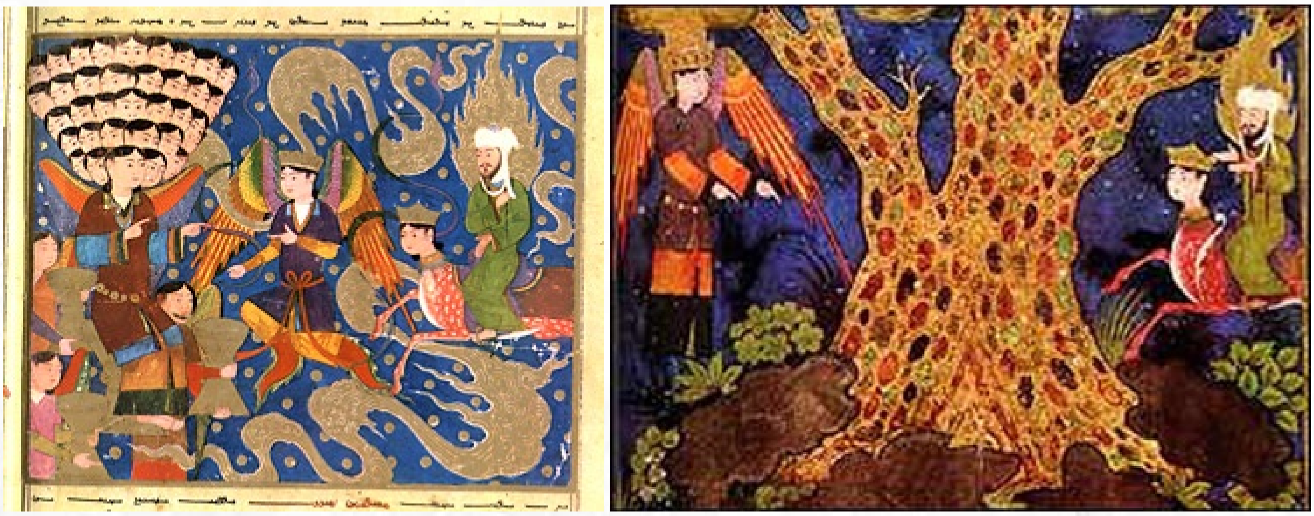
What is essential is that there was a fundamental shift in finding the singular entheogen in whatever cultural context to basically producing it my more and more sophisticated means as the alchemical literature amply illustrates. While this may delve into the issues of the loss of the soma identity and the related attempts to define it with a single plant identification on one level, what is more important for our purposes here is that alchemical tradition as essentially "entheogenic" in nature and there was a transition from a search to manipulation and production (Needham 1974). Yet a further dimension that combines the inner (*nei dan*) and outer alchemy (*wei dan*) could be the adept as alchemical vessel where his own body transmutes the active principles of the mushroom (ibotenic acid decarboxylated to muscimol) excreted in the urine which accords with the Vedic descriptions. This is not to reduce alchemy to the search for or manipulations of alkaloids but to express that entheogens represent an aspect of elixir alchemy.

While much of the theology, philosophy and medicines of the Islamic mystics no doubt comes from the Greeks (Tibb-e-Unani), there is sparse evidence of a Hellenistic elixir alchemy proper (though there is a rich entheogenic tradition such as the *kykeon*, *pharmakon athanasius*, etc.) and likewise, except for some apocryphal works, in the Jewish-Alexandrian tradition (Needham 1974). We must again rely on Needham to establish three provisional categories of alchemy: "gold-faking, gold-making, and the preparation of the drug of deathlessness" to which we may add that the terminologies of the various branches overlap and are interchangeable. Needham discusses the quintessential alchemical term "elixir" as having a possible Chinese origin and further links with the familiar "philosopher's stone and powders of projection" familiar in the Middle Ages. Madhihassan (1951) in discussing the etymology of elixir was dissatisfied with Arabic or Greek roots favored an origin from the complex of Chinese phrases such as *yao chi* "medicinal dose" and *yao chih* "medicinal mushroom" though he would offer other suggestions and the matter is hardly settled. Madhihassan's (2002) etymological treatment of elixir alchemy combines metallurgical and botanical associations with *kimiya* as a root for alchemy meaning "gold-making juice."

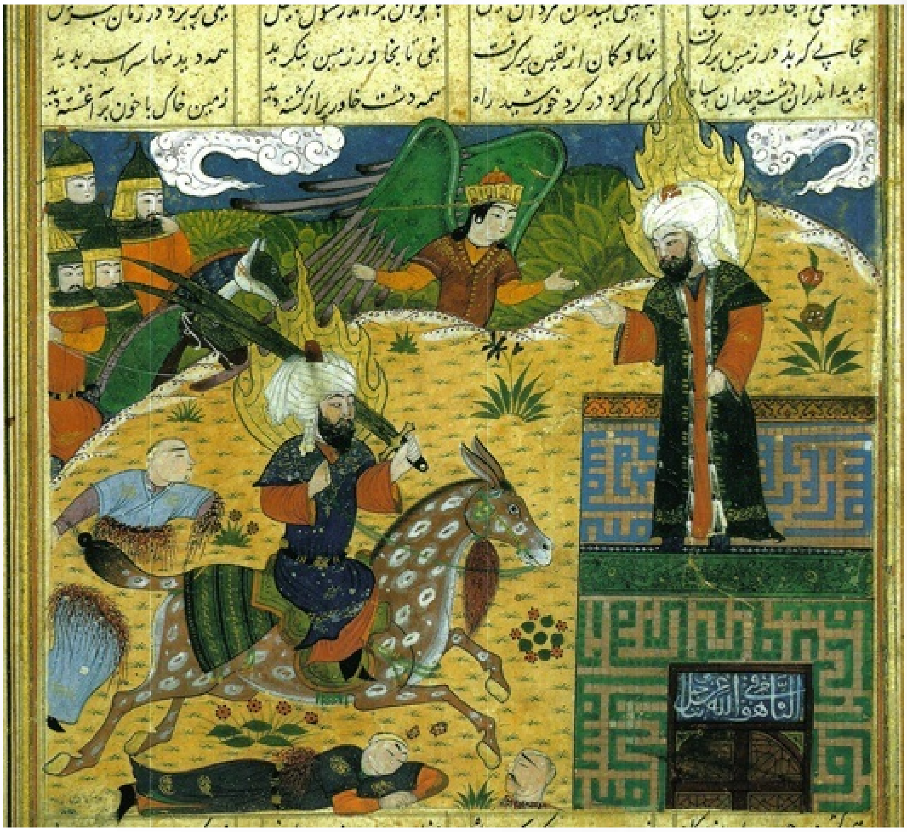
There are hidden realms in esoteric Islam that hint of a continued use of entheogens in the forebears of the Prophet, the Prophet Muhammad, and his extended house the Shia, and the cults that coalesced around various charismatic messianic figures. These cults preserve core doctrines and cosmologies as well as a tendency to radical autonomy and militant fervor to protect themselves and their religion.

Muhammad the Prophet Shaman

The prophet Muhammad spoke to the angelic messenger of God and underwent visionary initiatory voyages to the heavenly and infernal regions (1). He mounted the mysterious shamanic beast, *al-buraaq*, which means "lightning" in Arabic and which begins to draw associations with mushrooms, as they have ancient folklore links with lightning and thunder perhaps due to their sudden appearances after rains. Wasson notes that *Banat*'*u*'*rrad*, "Daughters of Thunder" are used as an expression for fungus, but an unnamed species, in the dictionary of classical Arabic in his discussion of "Lightingbolt and Mushrooms" (Wasson 1986). Though described in Islamic literature as being white and something like a donkey or a mule, the fabulous creature is curiously depicted in some examples of Islamic art as being red and white in a design consistent with *Amanita muscaria* mushroom, the entheogen suspected to be a major candidate for the soama/haoma and the symbolic colors of alchemy.



Note the angel is pointing down towards the tree where a mushroom is found and Buraq is red/white as in *Amanita muscaria*.



(2)

In the above images, Muhammad is seen riding the red and white creature, again the colors of the *Amanita* mushroom, in his shamanic night journey *isra*' and ascension to heaven *mi'raj* reminiscent of the ascent of Arda Viraf who takes a narcotic and takes a visionary flight through heaven and hell (Seguy 1977). This representation of *Buraq* may indicate that regional cults viewed the Islamic revelation through their own shamanic traditions or that Islam retained the ritual heritages of the ancient world. These traditions would be enshrouded in the mysteries of Shia gnosis, alchemy and Sufism that spread into Europe. The other image depicts Imam Ali on a similar creature with the red and white colors and in a scene entitled "Gabriel Shows Ali's Valor to the Prophet" from the 15th century Persian epic of Ali, the *Khavaran Nameh*, which shows his steed in these colors particularly in scenes of battle where it is grey in other scenes though more research is needed to fully develop these curious depictions of the changing mounts (Birjandi 2004). Another uncle of the Prophet Muhammad is Amir Hamza, whose folktales date back to the time of the Prophet and whose exploits unite Chinese, Indian, Persian, Greek and Arabian cultures, also rides a similarly described winged-demon steed *Ashqar* Devzad (Lakhnavi and Bilgrami 2007). This series of tales involves treasures under trees and occult lore of the Prophet Khizir and Imam Ali (even before he was born) in aiding in battles and traveling to the land of the *jinns* for temporal and spiritual *jihad* for the True Faith anticipating the coming of the Prophet Muhammad.

The mixture of *Peganum harmala*/*Amanita muscaria* (or a coded reference to the *haoma* type plant/mushroom) may have been used by early Muslims for entheogenic and military purposes as the etymology of *Peganum* has been linked with the flying-horse *Pegasus*. Flattery (1989) reports of another epithet of *haoma* that links "swiftness" and horses, like the flying horse Buraq which is as "quick" as lightening. There is the precedent for courage giving herbs in *hadith* such as is found in the collection of the theologian Muhammad Baqir Majlisi, whose collections are widely considered authentic in the Shia world. Amongst other more magical/medicinal uses of *harmal* in connection with the 6th Imam Jafar, there is related an incident wherein the Prophet complains to Allah the fighters are cowardly. Muhammad receives a revelation from God that the people should ingest *isfand* "by means of it they might become brave" (Flattery 1989). Other less reliable, yet still widespread hadith (controversial today in modern Egypt) record strange incidents of urine drinking (usually and obviously this would be *haram*) one of which is:

> "the Prophet SAW used to have a wooden bowl in which he used to urinate and place under His bed. One night, He searched for it but did not find it and asked for it saying, where is the bowl? The members of the house replied 'Umm Salamah's slave girl Barrah drank it' who came from Habashah with her. The Prophet replied, 'surely she has protected herself from the fire with a great wall'."

This is a most extraordinary hadith as are others that concern people going "beserk" after the Prophet told them to drink the urine of a certain camel, suggestive of ancient shamanic practices of drinking reindeer urine. Mixing bull urine with *harmel* is mentioned in Old Iranian rituals (Flattery 1989) and the incidents of "urine-drinking" incidents in Islamic lore, which are more than expected given the obsession with hygiene especially in toiletry, align with some of the key points of the identifications of *soma* and shamanic plants as suggested by Wasson (1978). The epithets of *haoma* of having a "hundred waters" are suggestive of a diuretic effects as well as the profuse perspiration experienced when ingesting *Amanita muscaria*/*Peganum harmala*.

There is an argument to be made for the initiation of Muhammad at a very young age into a desert brotherhood that definitely was Eucharistic in character. This complex included a "Shiite grail liturgy" (Corbin 1998) that accords with the research of Eisenmann (1997) in linking exoteric and esoteric doctrines of the Shia Gnostics with the early Christian mystics. Muhammad declares his son-in-law and cousin (though again in the literature this relationship is sometimes conflated to nephew/uncle) Imam Ali: "Thou art the Knight of this community" and performs a "ritual of the Cup" that might point to pre-Islamic rituals of which will be discussed below. But considering the decidedly Gnostic and increasingly mystical revelations of each Shia Imam, especially the 6th Imam Ja'far, the Shia tradition through Imam Ali can be seen to represent rituals and contexts more in sympathy with ancient mystery schools than Sunni Islam (Corbin 1994). Muhammad's uncle, Abu Talib, is controversial in Islam with the Sunni slander that he was never a Muslim which contrasts the Shia veneration that dismisses the Sunni version as a plot against the family of the Prophet in collusion with the Umayyad, the rival clan of the Hashimites of the Prophet Muhammad (Shirazi 2001). (3)

These symbolic rituals of cups and military brotherhoods partakes of an entheogenic legacy extending back into the earliest Indo-Iranian cults discussed at length by Eliade and Dumézil. The groups become literally berserk with intoxication, and their lycanthropic ritual consisted of "those who change themselves into wolves (*varka*) in the ecstasy brought on by soma (*hauma*) (Eliade 2006). The mushroom *Amanita muscaria* is at once ritual sacrament and entheogen, medicine, and combat stimulant and its powers may well have been a factor in the military success of the early Muslim fighters who had their own warrior brotherhoods waging *jihad*. The Indian verses of soma connect to furious battle with such verses as "Indra, the man god who drinks soma, becomes stimulated for battle after drinking soma" (Rig Veda 9.44.3; 9:97.37; 5.44.13). Converging on these syncretic Islamic traditions from multiple angles of influence is the knightly mysteries of Mithras. The military nature of these fraternal devotees also contained an initiatory ritual for the soldiers that were connected with a sacred cup and visionary Eucharist (Hoffman, Ruck and Staples 2002;Ruck *et al*. 2004). Mithras is also associated with caves, cups and ecstatic mystery rites and it must be remembered that Muhammad received many of his revelations in a cave The Cave of Thor (Ghar Thour).

Franz Cumont (1956) mentions there are many similarities in cosmologies with the Gnostic Mazdeans that retained much of the fleeing teachings attributed to what Eisenman called the "Opposition Alliance." This military alliance reveals the strange mix of herbalists and healers with military mystics. As Cumont (1956) again states, "the Mithraists' most profound religious beliefs were associated with the miraculous creation of "beneficent plants" and further that their symbolism is often grouped with a "krater" or cup that was used in "divine feast and probably drank of the wine which conferred immortality." It was the clear connections of Eucharistic meal, of communion of "bread" and "blood" and immortality that prompted Justin Marty to presume the entire affair was a blasphemous parody of the Christian Euchasrist. Dr. Moghdam (1975) writes of the Iranian origin of "the divine meal, the Lord's Supper, apparently the Cup used for the 'nushabe' (water of immortality, in Islam becomes the *Maul-hayat*) became the holiest object in the service. That cup figures very prominently in Persian literature and especially in the mystical poems. The cup has seven lines or measures corresponding to the seven degrees in Mithraism. The full cup is for the Pir or the Father, who is known as the Pir of the seven lines. In the West it gave rise to the 'Graded cup', Latin 'gradalis' or grail. The lore of the Holy Grail and Arthurian legends are discussed in terms of entheogens by Heinrich (2002) and related folklore by Ruck (2007) demonstrating the persistence of these associations. Moghdam (1975) further states "As to remnants of Mithraism in Iran, at its best it survives in Iranian mysticism represented by the Divan-e Shams, the Golshan-e Raz, and above all, in the poems of Hafez, and of course in the strong influence it exerted on Islamic Sufism, which is quite distinct from Iranian mysticism." He adds "In sects, there is a survival of Mithraism in the Ahl-e Haq and the Yazidis, and other small sects scattered in closed communities" which I have already discussed in terms of entheogens (Dannaway et. al. 2008). The "red-heads" or Qizilbash, extremist devotees of the Imam Ali, are a mystical calvary, "convinced of the invincibility" and throw themselves into battle with no armor after wild orgiastic parties, and they are even accused of lycanthropic cannibalism (Rudi 2005). This group might suggest a continued use of entheogens in extremist, militant sects that would exploit the herbal uses for war purposes as discussed above in the context of Shia hadith.

The radically Gnostic and syncretic traditions of the earliest Shia, such as the first Imam Ali who speaks of alchemy in the highest praise, presents a problem that is solved when Shia Islam is viewed as the fruition of a coherent doctrine of visionary plants and alchemical elixirs. Either the Shia are immediately arch-heretics to Islam, as the Sunni maintain, foregoing and betraying their Prophet, Uncle/Father/Grandfather the moment he is buried or they, and they alone, retain the true doctrines of Islam as taught by the Prophet. This would require the belief that the Imams themselves spontaneously adopted extremely complex esoteric doctrines over the assumption that these practices represented a core occult doctrine of Islam taught to the chosen few. The previously discussed currents that find exact and clear examples in the Shia gnosis can be linked with the Syrian and Sabian traditions in such a way as to make Muhammad's protection to them make perfect sense. Muhammad's recognition of "People of the Book" (*Ahl al- Kitab*) raises him to the level of a reformer of the religion of Abraham that had degenerated into corrupt idolatry. The Prophet was initially accused of being a Sabian ("washed ones") by his adversaries and they had nearly identical practices of ablution and obsession with purity that still characterizes the Shia today (Green 1992). The living, breathing and actively appropriating force that could be described roughly as Hermeticism is the thread that binds these traditions. The Syrian city of Harran possessed the old astrotheological lore that was certainly one essential component to these mystery cults Green (1992). The city's location and Syria's in general, makes it a fertile area for cross-influence from the well known entheogenic mysteries of Greece and Rome from one direction and the *soma*/*haoma* astronomy cults coming from the other.

The Semitic material, via fleeing Gnostics and converts, met with a region familiar with the passing fancy of exoteric doctrines of what amounted to the same "mystery." This mystery is undoubtedly that of spiritual immortality and the reverence for the plants that produces the visionary experience that imparts the feeling of death and rebirth in the context of the Logos made flesh either in the Prophet or Imam. The Krater as the vessel for this pressed (*haoma*/*soma*: Indo-Iranian root *sav- "to press") substance that bestows immortality always appears with similar descriptions. From the "Lady with the Mead Cup" Indo-European cup rituals to the indigenous "grail" myths of Ireland its associations always retain the same striking characteristics (Enright 1996).

The Hermetic material, which was preserved in Harran, was given prophetic status as a revealed book in Islam and garnered the fascination of mystics in every tradition with which it made contact. The Hermetic *Krater* combines the baptismal, or bathing purity cult, and the "symbolic drinking of knowledge" together with mystic piety and "initiatory brotherhood." The Hermetic material also provides the common terminology that characterized much of these ancient mystery schools of the "universal man/perfect man/Logos/standing-one/Imam" that is evident from the Mithraic and Christian cults to the Shia gnostic and Sufi. The Logos-Nous is described in its liquid form as a holy beverage, or as one Hermetic treatise states, "And I sowed in the words of wisdom and they were nourished with the ambrosian water." A variant is, "Those who are able to imbibe somewhat more than others of that vision attain to full fruition of that most lovely sight." The astrotheological connection with the constellation Krater is discussed in the Hermetic material as being the "drink of oblivion" (lethe) that souls drink from on their descent into the earth. It is therefore an act of cyclical "rebirth" to drink of the earthly cup of knowledge, the Krater, and to imbibe the divine fluid that wakes one from the sleep of forgetfulness that overtakes the soul. The symbolic drinking of knowledge or "drinking the Word" gives the vision of God and grants immortality echoing the praises of the *soma*/*haoma* of the Vedic and Iranian Gaokerena of which it is said, "those who drink of the life-giving juice of this plant will obtain perfect welfare, including deathlessness" (Corbin 1989).

The alchemist Zosimus, an immensely significant figure combining Greek and Egyptian traditions in Islamic alchemical literature, has writings which discuss:

> "the uncommunicated mystery which none of the prophets dared to divulge in words but revealed only to the initiated. In their symbolical scriptures they called it the stone which is not a stone, the thing unknown yet known to everyone, the despised thing of great price, the thing given by God and yet not given. For my part I shall praise it under the name of the thing given by God and yet not given, for in all our works it is the only thing which dominates matter. Such is the drug of power, the mithriac mystery" (Needham 1980).

Likewise, the *Kitab al-Zibaq al-Gharbi* (Book of the Western Medicine) discusses this stone that is not a stone, with "Know that this 'water' has been named Divine because it brings the qualities out among the qualities and revivifies the dead; therefore it has been called the 'Water of the Living Things,' just as the stone has been called the 'Animate Stone'. It is the Water of Life and he that has drunk of it can never die..." (Needham 1980).

The celestial Krater is linked in Vedic star lore with the *soma* cult of immortality, and of course the constellation that retains that name. The Krater as "cup of immortality" acquires a sophisticated level of technology in the Hermetic material. Some scholars maintain that "the topos of the Krater as a vessel filled with divine substance is a gnostic continuation of the Jewish Sophiaspekulation" and "it is closely related, within the frame of pneumatic doctrine of grace, to the other gnostic topos of the potion of gnosis, where the receiving of knowledge is compared to a drink. The entheogenic aspect is quite clear with the observation that "the expression 'to drink gnosis' has basically reached the status of a technical term." It is this same "technical" language which prompted John Allegro to make his radical case about the true nature of the Jewish religion and connection with the manna, or mushroom of immortality, which Robert Graves also suggested as discussed below.

Littleton and Malcor (2000) take a bold step following Dumezil and then going him one better to make a solid argument for a "Scythian" influence that converges in the pre-Christian grail myths. The obvious guess is that all traditions proceed from some yet unknown proto-IndoEuropean like race that even in a remote time possessed some complex "ecstatic wisdom." The Grail myths themselves yield evidence for nearly all possible origins, from the Iranian and Scythian/Alanic sword in the stone to the discussed cup/military correspondences. The circumstances that surround the Grail do seem to nearly always retain a Middle Eastern characteristic, no doubt from Crusade influences, but they are many and persistent enough to lend credence to both Kahane and Littleton/Malcor's conclusions as to a pre-Christian tradition which was subsequently Christianized. There are abounding textual references to Saracen comrades and Moorish persons appearing at the strangest times and places in Wolfram von Eschenbach's Parzival (Eschenbach 2006). Various instances such as the heathen "kyot" who was skilled in stars and herbs is deciphered my scholars as having to be either of Jewish or Muslim origins.

This Guyot (kyot) is the source for Eschenbach's version which Wolfram is clear to distinguish as the "true version." Parzifal is at various times described as either being "Moorish" or related to a Moor, or involved with a Moorish Princess. Eschenbach claims his source is a Moorish document claiming the secrets of the Holy Grail and the brotherhood that guards it from the profane. Corbin (1998) describes the appropriate context of the Shia Grail liturgy with the word *futuwwat* of which an approximate translation may be "knightly chivalry." He describes it as "deeply rooted in Shiism, and more generally in Islamic esotericism." Corbin notes the similarity with rituals appears in the "flowering of the European trade-guilds, such as the 'Compagnon du Devoir' in France" as well noting the affinity with the "signs of recognition" associated with the Druze and Scottish Rite Freemasons (Corbin 1989). Mohammad instituted the "ritual of the cup" and also symbolically passed the Mantle (*al-kisa*') of Prophecy to Imam Ali which in turn spread throughout the Islamic world in both Sunni and Shia groups. The lore of Imam Ali and his famous sword 'zulfikar' bear a strong association with the Excalibur of Arthurian tradition. Another of many links to grail lore parallels with King Arthur who was said to be the only one to pull the sword out of the stone there is a very popular Shia legend that none but Ali could pull Zulfikar from its sheath and various cults in the region worship a sword stuck in the earth. Corbin notes the Prophetic tradition that records that in Mohammad's youth there "existed a chivalric order (*futuwwat-dari*) whose ritual involved a cup of wine," though this could well be a common term for any intoxicating liquor. This tradition does involve Muhammad's same uncle (he was a *widow's son* like the Grail heroes) that took him to Syria, Abu Jahl, who completed the ritual "with four hundred comrades." (4)

This would go further in supporting the Syrian initiation claim of Muhammad with his uncle. Syria mystery traditions had special rites for foreign children in a "secret house" (bayt sirr) and "dark temple" (haykal muzlim) (Green 1992). Corbin's research also highlights the all important distinction that there were two "cup rituals" within the Muslim community. The Shiite version was for the "servants of light," again recalling the Qumran terminology, and was a cup with the "Wine of Malakut" which is a liquefied substance that, whatever it was, induced powerful visionary results into the realms of light. The ritual of the "drink (wine)" is as Corbin again states, "named for the Malakut (the spiritual word which includes the *mundus imaginalis* '*alm al-mithal*' or world governed by Angels) ...(which) shows that were are dealing with a sacred ritual, and that its action occurs in the visionary world." The situation then becomes of an initiatory ritual of a liquid substance that launches one into the visionary world that was instituted by the Prophet Muhammad and sustained in the Shia community. The secretive Nusayri/Alawi are already discussed by Eisenman as retaining exact terminology and symbolism of the earliest "gnostic" Christian that persisted and mixed with the other discussed traditions in Syria. These Nusayri have their hymns and liturgy drinking their wines of "servant of light" ('*abd al-nur*) which isn't likely alcoholic in the Islamic tradition Sunni or Shia (Bar Asher et. a. 2002). Then the hadith presents stories of Muhammad learning a cup ritual from his uncle with whom he journeyed to Syria. This ecstatic tradition is characterized in visionary experience and angelology that mixes Mithraic and Persian terminology freely with esoteric Shia doctrine and is quite distinct from the Sunni version. The Shia versions for the knightly "servants of light" has all the characteristics of the European grail as in various traditions of immortality, "always full" of the "source of life" ('*ayn alhayat*).(4) One devoted extremist Shia sect, the *Kizilbash*, or the "red heads" seem a likely group to continue these traditions as they were militant supporters of the Shia Imami tradition.

Henry Corbin's (1994, 1998) work on Mazdean and Shi'ite traditions in Iran reveals several dimensions to an "esoteric Islam" that include some aspects directly related to ancient entheogenic traditions. Corbin discusses integration of the rituals of the old Mazdean divinities into the angelic hosts of the Gnostic Shia Muslims including a *haoma*, Gaokarena, "of which it is said, 'He who partakes of it becomes immortal" and it is an Elixir of immortality (Corbin 1989). These symbolic associations transfer with the revelation of Islam to a host of angels, where each has a botanical association with a flower or plant in a very eloquent "sacred botany." The folklore of various plants in the region associated with *haoma*, such as the *harmal* or *isphand* plant *Peganum harmala* are well discussed (Flattery 1989) and recently in an article of Moses and the burning bush, though this theory has been suggested before (Shannon 2008). The *harmal* of *isphand* (*Pegaganum harmala*) ingested alone is entheogenic, and intimately linked with the Shia Imams, could be active by a subcutaneous ingestion by way of dyeing the elaborate geometrical carpets famous throughout the Islamic world, a principle use of the plant to obtain the brilliant red hue, and the use in the dyeing of the fez may well "color" the sweating spinning dervishes of certain Sufi orders. Bioassay of entheogenic doses of *Peganum harmala* have reported the feeling of "contact" with an invisible being which might recall the initiatory prophet Khidir, in whose steps flowers grow. Modern Mazdean Gnostics employ the stimulant herb *Ephedera* which was an early substitute for the haoma but there is some interesting research on the interaction of *Ephedera* and *Peganum harmala* (Flattery 2004).

In the same context of the recent theory published on the use of DMT producing plants and Biblical prophets (Shannon 2008), the pre-Islamic cult of the goddess Al-Uzza yields similar plant species. It is said the goddess would reveal herself in a grove of three acacia trees in Mecca, which contain the powerful entheogenic DMT in *ayahuasca*, and whose symbol was the crescent moon and the morning star. In ancient times she was considered enshrined in the Ka'aba where she was served by an order of priestesses. The black stone to this day is cared for by the Beni Shaybah, "the sons of the old woman." AlUzza becomes a source of serious contention, famous in the "Satanic Verses" as one of the daughters of Allah and though her sanctuary was destroyed some scholars note she is still called upon in times of sickness of certain of the faithful. Alexander Shulgin (1996) in his classic *Tihkal* cites ancient beliefs from the Near East and Egypt of "a balsam or oil peddled to the priests of yore by Bedouins, which claim it to have come from the "original" Tree of Knowledge" which existed at the lowest point on earth near the Dead Sea and Sinai Desert." Of course this oil is from the acacia. The goddess revealed in an acacia grove is suggestive of an entheogenic experience and at least places two plants that combine to form an ayahuasca like potion in the same region and in cults that formed the syncretic faith of Islam. I have argued for the Islamic use of ergot and other psychoactive plants elsewhere (Dannaway, Piper, and Webster 2006) and speculate that either specific plants represented different cults or sects, with the predominance of the specified ritual plant evolving with the various religious expressions pre-Islamic and Islamic, or else there was no single ritual plant and many psychoactive plants were used in various ritual and initiatory capacities. Perhaps Muhammad's cult of the mushroom supplanted the pagan DMT cult, or perhaps it was appropriated into the Shia rites as discussed below. Perhaps Muhammad reformed traditions that were originally monotheistic and which had lapsed into a degraded and corrupt religious hierarchy that would continue to assault his house.

Interestingly, the much maligned and increasingly vindicated linguist John Allegro (1970) writes of various "rue" species, which could be *Peganum harmala* or *Syrian Rue*, in connection with *Amanita* mushrooms perhaps to potentiate the effects in some species and to alleviate overdose in others. Allegro sees an esoteric word play "between the Aramaic *mestebit ha*' "submissive" and the mushroom name MASh-TAB-BA-RI-TI and its possible source for Muhammad's teachings", as his followers are called Muslims "the submissive ones." Allegro also suggests entheogenic fungi at the heart of the Ismaili of the Old Man and the Mountain and his famous Assassins, popularly but not necessarily linked with the use of *Cannabis sativa*, though the term hashish can mean any dried herb. The very interesting speculation of the Day of the Zulu involving the consumption of *Amanita muscaria* as a war drug to give superhuman strength and fearlessness (Knight 2006) is an attractive hypothesis to the military success of the Muslims against some insurmountable odds. The Koran speaks of the Battle of Badr:

> Allah had helped you at Badr, when ye were a contemptible little force; then fear Allah; thus May ye show your gratitude. Remember thou saidst to the Faithful: "Is it not enough for you that Allah should help you with three thousand angels (Specially) sent down? "Yea, - if ye remain firm, and act aright, even if the enemy should rush here on you in hot haste, your Lord would help you with five thousand angels Making a terrific onslaught. Qur'an: Sura 3:123-125

This could allude to mushrooms as "angels" taken by the faithful before raging into battle. Ruck (2007) has reexamined the role of *Amanita muscaria* in the war-fury of the Berserkers and if this "technology" was known throughout the ancient world then perhaps the Muslim armies made use of the mushrooms to their ultimate success. The PBS documentary also featured to martial artists equally matched in the past in an experiment in which one is given a placebo and the other *Amanita muscaria* with the results of the bemushroomed fighter abandoning his technique and just dominating his opponent in every way in a combative fury (Knight 2006).

Yet another source of entheogenic traditions could derive from the Zoroastrian Magi Salman al-Farsi who went on a mystic quest that brought him to Syria and finally, after being sold into slavery, into company with the Prophet Muhammad where he is highly honored as a mystical patriarch. In the mystical Alawi tradition that splintered after the 6th Imam Jafar, the Imam Ali, Muhammad, and Salman al-Farsi are the "Idea, the Name, and the Door (to God)" respectively in a trinity which is a doctrine that both unites and divides various Christian churches. The Nusayri-Alawi venerate Imam Ali as the *amir al-nahi* as the "prince of bees" which also has entheogenic connotations with bee's and honey in a vast array of folklore and alchemical literature (Ruck 2007).

Spiritual Flight and The Cult of the Severed-Head

Yet another curious recurrent theme amongst these various groups is the oracular or prophetic "talking heads" that partake of associations with *soma* from ancient times (Kramrisch in Wasson 1986). The "Secret of the Cut-Off Heads" is one of entheogenic mushrooms, particularly the sacrifice of the mushroom's "head" perhaps with the intent of keeping the mycorrhiza intact. Kramrisch decodes myths of those "losing their heads" with mushroom intoxication and magical horses that reveal "the sweet secret" of the *Soma*. There is a tradition of "Headless Magicians" with Soma links and the "act of truth" in an initiatory complex that extends this ritual symbolism into the fringes of the occult in the ancient world (Coomaraswamy 1944). Heinrich (2002) links the beheading with mushrooms and the initiatory circumcision as well as the prophetic head of John the Baptizer. He quotes the *Apocryphon of James*, of the Nag Hammadi texts, linking John's severed head with prophecy and a riddle by Jesus that begins with, "When you come to know what "head" means, and that prophecy issues from the head, then understand the meaning of "Its head was removed." Heinrich also links the severed head motif in alchemical manuscripts, such as in the *Splendor Solis*, with the Vedic legends, such as the six headed god Skanda that indicate the mushrooms were cultivated by careful harvest and other techniques to ensure the supply.

One finds many legendary beheadings in pre-Islamic and Islamic legends but some definitely conform to these established connections of magic heads and mushrooms. One of the previously mentioned uncles of Muhammad, Amir Hamza, beheads many foes but in a garden of jinns and might *ifrit* he beheads a youth and proceeds into a series of magical chambers that ultimately leads him to his magic steed. The head of the third Imam Hussain was said to speak after the massacre at Karbala and a legend maintained by the Kizilbash (red head, as in the mushroom) Kurds describes an Armenian priest who, recognizing the head as supernatural, wanted to retain the head then on its way to the Umayyad Caliph Yazid (Moosa 1988). The priest's eldest son offers his own head as a substitute to fool the Sunni and the priest instantly deprives his son of his head. He cuts off six heads out of seven sons to convince the murderers, which must remind one of the six-headed Skanda mushroom-god who is similarly beheaded. The ruse does not convince the Sunni murderer's until the seventh son is decapitated which apparently somehow convinced their foes. The priest thus retains the head in secret and adorns it with precious metals where it eventually impregnates the sole daughter of the priest having transformed into a bowl of honey, and the legend explains this as the origins of the birth of the 5th Shia Imam al-Baqir.

The implications of a complex of oracular-heads and entheogens must wait for a future paper, but some revealing clues are scattered around in popular myths such as is found in the Knights Templars and their strange talking-head Baphomet which has been discussed as a possible corruption of Mahomet. The somewhat controversial Sufi Idris Shah (2002), working with Robert Graves, speculates an Arabic origin meaning "Father of Understanding" and links with the Sufi *ras el-fahmat* (head of knowledge) that has an oracular function. The Sufi master and Persian poet Farid al-Din 'Attar (the druggist) has many poems that describe the Seeker as wandering, "iterant and headless" though his poetry on wine and drugs are treated metaphorically such as the scholarly discussion of his "spiritual flight" which contains a chapter *On Losing One's Head*... though in the context of spiritual boasting and authority (Lewisohn and Shackle 2006). 'Attar's poems offer complex symbolism, such as this verse which is consistent with heads and entheogenic wines and the Sufi mystic Hallaj who was executed because he declared "I am the Truth" (*Ana'l Haq*) in religious ecstasy.

"They saw Hallaj in a dream one night, his head cut off, but with cup in hand. They asked, " How is it your head is cut off? Tell-how long you have chosen this cup? He said, 'The king of blessed name gave this cup to the headless one. Those who forget their own heads can drink from this spiritual cup." Clearly there is some relationship between these headless mystics, the "Grail-head" and the various oracular heads as well as perhaps the *caput mortem* (dead head) of alchemy and "cult of the severed head" in Ireland. Scholars debate these associations but not attempt to place the overwhelmingly similar and shared themes that inform the myths of the Templars and the Grail legends (Nicholoson 2001), though Ruck (2007) and his fellow scholars have unearthed many details of "heads" in European fairytales. Sufi seekers such as in the Nimatullahi Order bring a whole nutmeg (*juz*), symbolic of the head, as representing their head sacrificed to the Master (Netton 2000). This might reflect a substitution from the mushroom for the potential initiate for the symbolic nutmeg as Sufism became more institutionalized.

The theory of Syrian initiations is bolstered by the research of Green (1992) that links these cults of the head with alchemical and astrotheological lore of the Hermetic center of learning that was Harran. This research discusses a secret metallurgical guild of alchemical initiates who have a cult of a prophetic head (*al-r'as*) and Harranians were accused of being "Adherents of the Head" (*Ashab al-r'as*) which is described as resembling the god Mercury ('*Utarid*). The head is pulled off in chemical operation at certain times when the planet Mercury is exalted and "it spoke" is similar to other "prophetic heads" found in Arabian magical texts and in the Jabirian corpus, which gives instructions for using prophetic severed heads. These traditions are discussed in the context of Indian astrology and alchemy and Sabian magical texts that discuss oracular heads. The Syrian mystery cults that are linked with the esoteric Shia sects retain the curious lore of the "heads" that may well be the source for the reemergence of the cult in Europe and the charges against the Templar Knights in worshipping the idol head Baphomet as well as "Grail-head" myths from Irish folklore.

Shia and Sufi: and the Mantle of Gnostic Islam

> "Alchemy is the Sister of prophecy"
> *Imam Ali ibn Abi Talib*

The religion of Islam is too often studied, even by scholars, through the eyes of the Sunni and much of the information on the Shia (the party of Imam Ali, the Prophet Muhammad's grandson and son-in-law) is fragmentary, misunderstood or from polemical sources. I have a perhaps radical theory of the Shia, in that I view them as in many senses a much more "legitimate" representation of Islamic theology and cosmology. An example would be the Shia insistence that the Prophet could not only read but was well read and highly educated, a fact which Sunni and many scholars deny, and I suspect because this makes the Koran appear more of a miracle if from an illiterate camel driver, even though it contains some very pagan elements obviously incorporated into the text to link with and either replace or fulfill prior traditions (Stetkevych 1996).

Flattery (1989) collects several Hadith and poems that illustrate nearly identical phrasing in praise of the Syrian rue or *harmal* plant and quotes the 6th Imam Ja'far and his teaching that *harmal* seeds ward off evil influence which resonates with its continued use in Turkey and Iran as a method to avert the evil eye. But Imam Ja'far, perhaps the most "esoteric" of all the Shia Imams, which traditions holds as the revered master of the alchemist Abu Musa Jabir ibn Hayyan, known and translated into Europe under the Latinized moniker Geber (though this is debated as to what extant). The word gibberish is said to have originated from Jabir and his near hopelessly obscure alchemical writings but his work is laced with metaphors of red lions and special mention of the "elixir of the prophets." Jabir (likely a complex of initiates writing under one name) called Imam Ja'far his master and he wrote an interesting alchemical treatise called the "Book of Venus" that deals with matters of a "special red sulphur." There is an anecdote about a sick concubine and our alchemist has "a certain elixir with me, and gave her a draught...with vinegar and honey," effecting a cure much to the relief of the Caliph (Holymard 1957) *harmal* is still used for heat exhaustion and "magical" illnesses. It is interesting to note the possible role of *harmal* both as medicine and entheogen, and we might note that vinegar or acetic acid removes the "lion's share" of alkaloids, and yet-tobe translated botanical Hadith of the early Imams prescribe such concoctions with honey for a variety of illness. Scholars, such as Syed Nomanul Haq (1994), trying to make sense of Jabir's immense body, of work suggest that the intermittent scholarship that is interrupted by nonsense and irrelevant interjections does not indicate a lack of substance but rather indicates that Jabir was following a specific tradition to obscure his language for the uninitiated.

The "Principle of the Dispersion of Knowledge" (Tabdid al-ilm) is like modern artistic deconstruction in which the work is completed, cut up and placed at random throughout the entire work. The final product thus hides behind scattered references like a puzzle in which the dedicated must have the entire corpus in order to make sense of the "secret." In the Works of Geber there is constant reference to the "red stone" and the meaning is clear that these are not the common materials known by the names such as mercury and cinnabar, but rather "hypothetical" substances that induce a spiritual transmutation. The language of an alchemical entheogenic cinnabar is familiar, with similar references in the diverse alchemical traditions. The Mao Shan tradition of Taoism is known to employ just such precise language of a red cinnabar and practiced rituals that were made fragrant by "hemp-laced incense" (Saso 1990) and Needham repeatedly suggests "hallucinogens" at the very heart of the Taoist cannon and Chinese alchemy (Needham 1975). Al-Hakim, another alchemist, also the Mad Caliph of certain infamy, is said to have written a document of a "Red elixir of Moses and the rest of the Prophets" (Holmyard 1990).

This preserves a tradition passed down from antiquity to the 6th Imam Ja'far whose legacy is draped in occult insinuations. Imam Ja'far was the last Imam held in common between the different Shia sects of the Twelver, who continue the line through Ja'far's younger son, and the Sevener who believe the position of Imam went to the senior brother Ismail of which the Ismaili trace their ascent to the present day through the Aga Kahn. The alchemist Dubais ibn Malik records this tradition in his writings of a fine jeweled amulet of which he comes into possession. He relates that on the inside there were two manuscripts of two recipes written in the shaky handwriting of Al-Hakim of which he was certainly familiar given Malik's somewhat privileged position in Hakim's court. Al-Hakim was accorded divine status by some followers, the Druze, who persist to this day in Israel, Syria and Lebanon despite incessant warfare and persecution. Many, perhaps credulous, writers assume Masonic connections with the Druze in terms of symbolism and structure. Further investigations might include their noted use of a botanical as means of identification amongst themselves. Al-Hakim was also castigated as a lunatic by others but his links with Hermetic documents and connections with the Brethren of Purity (*Rasa'il-e Ikhwan us Safa*) and the *al-batiniyyah* (the esotericists), suggest more than just a simple case of a deranged monarch.

Alchemical historian E.J. Holmyard (1923) translates an alchemical treatise by Al-'Iraqi, Knowledge Acquired Concerning the Cultivation of Gold, which discusses the necessary elixirs (al-iksir). This partakes of the language of the Indian and Chinese "potable gold" that finds its way through Islamic alchemists into Europe (Needham 1975). The emphasis is that one should be hot and red, the second cold and white, which is the constant theme of the work, and sometimes uses the designations of silver for the white and the gold for the red in keeping with the metallurgical code. 'Iraqi informs his readers these secrets are guarded by the sages and "all were very jealous of it even with their sons, and more so with the rest of men." His discussion on the "first matter" of the operation proceeds to the language of an alchemically prepared food or salt which is the seed of a "metallic-plant."

This prima materia is further described as a tree that grows "in the lands of the West" with blossoms of red and the second is a blossom between red and black, divulging the recurrent themes of these specific colors of the *haoma* and *soma*. 'Iraqi says of this tree that whoever eats of it 'man and jinn will obey' and also notes "this is the tree of which Adam was forbidden to eat." These alchemists describe their potion or elixir or stone in various terms of which many identify the familiar red sulphur, or the Ruby or Red lion known throughout the universal works of alchemy. This is the Philosopher's stone or "Red stone" that is the goal of alchemy. Needham (1954) curiously mentions a "laughing mad stone" which was called "*al-bahit*" which drove people mad when they saw it, laughing them selves to death. There are scattered mythological references to such a stone, such as in the "Alexander-Romance," but most interesting is that it garners an entire section in the alchemist writings of Jabir, the *Kitab al-Bahit* or Book of the Surprising. It shows up again in the Kitab al-Sumum or Book of Poisons of Ibn al-Wahshiya and even in the Latin Picatrix which was of an Arabic source as well as being mentioned by the Sufi saint Ibn Arabi (Elmore 1999). Needham writes, that "it may well be something very solid beyond these mythological ghosts and shadows. For was indeed in China a hallucinogenic mushroom which leads to uncontrollable laughter and may well kill in excessive doses." Whatever the implications of this, there seems to be a connection to mushrooms and Needham is perhaps the first author to directly discuss alchemy in the context of psychoactive plants and entheogens.

Friends of God

The Gnostic Shia have multiple sects, including the Fiver (Zaydi), Sevener (Ismaili), and Twelver (*Ithnā'ashariyya*) and if one counts with the latter eleven of the 12 were martyred. The Shia Gnostics seemed to have publicly split with the Sufi at the time of the 8th Imam al-Rida perhaps in another act of dissimulation ("al-Taqiyya") discussing their wisdom as the gnosis (irfan) as the Shia suffered ironically from being called "people of innovation" (Ahlul Bida'ah). What is critical to this discussion is to establish what would seem to be a line of transmission that is pre-Islamic in origin that came to fruition in Shia Islam with the divergent currents of the Twelver and the Sevener or Ismaili Muslims and in some Sufi sects. That the former transmission spread to Turkey is not open to debate, though how much of the original Iranian influence filtered through the predominately Sunni country of Turkey is still an issue in academic circles. The Shia influence merged with an existing Asiatic current is well established as in "the golden chain of Sufism in Shi'ite Islam," or *Tuhfah yi-Abbasi* (Khursani 2008) and the various chivalrous orders of Islam (Shah-Kazemi and Lewison 2007).

The Bektashi order of dervishes displays a wealth of indigenous shamanic influence from incantations and ritual dance to the ritual sacrifice of sheep or ram to the miracles and shape-shifting of saints so there would be a ready understanding of new initiations involving entheogens, they would likely even be expected. Their veneration for nature and sacred groves further suggest Asiatic influence and as Prof. McElwain (1983) of Stockholm notes in his article "Ritual Change in a Turkish Village," there is a plethora of evidence to "indicate a possibility of a Jewish or occult strand in a tradition already swollen with syncretic origins." Later in the same article Dr. McElwain describes the difficulties of translating these mystic poems and for our purposes we might note his comment that certain episodes present particular challenges of which some consist of, "drug-induced trips in some cases or pantheistic flights of ecstasy "which becomes extremely pertinent to this discussion.

The poem he translates under the name of Ali Hayder seems to originate in the 16th century and the author is noted to be Muhammet Amet. The verse is a lamentation of a ritual nature dealing with, as the title suggests, sacrifice, a concept emotionally and spiritually linked with the plight of the party of Ali, the Shia, who have faced unbelievable horrors and persecution. Here the act is in honor of the Twelve Imams and the brutal history of the house of the Prophet that was heir to the "green mantle" of authority through the offspring of the Prophet's daughter Fatima and Imam Ali, the prophet's cousin and son-in-law. This poem has a particular focus on the first three Imams Ali, Hasan and Huseyin. The language reflects possible ancient connections between man and the welfare of the land and people and is even suggestive of prehistorical human sacrifice, an idea which might still impact the now metaphysical self-sacrifice to the glory, honor and service of the Twelve Imams.

A sixth pillar in Shia Islam is social justice and it is interesting to note that these Shia dervish orders represented a struggle against the corruption of the Ottoman Sultans, a further connection with this theme of sacrifice. In the third portion of the work the poem conjures a tension that is consistent with themes of an ordeal and subsequent initiation. There is the imagery of knives and lances and a naked candidate. There is an inner light in a sip of wine, while the Pir, shakyh or master, whispers into the ear of the aspirant and an oath is taken binding the initiates into a ceremony designed to occupy all the senses to facilitate the sacrifice and rebirth, recalling not only the wise words of Christ but also the rituals of Freemasons. The wording in the poem suggest that some impending theophany is to occur, the sacrifice of the ego into the unity of Allah, and this direct interface with reality as in "Lets hand in hand on the Truth take hold" while the innocent is in a "pit of misery on one dark night" of the soul we might assume and "to be satiated with the drink came I" again recalls the Iranian motif of the haoma. The next verse is so crucial to this line of discussion that it must be quoted in full:

> "The juice of the pounded peony was giving Made drunk whom for love of Truth gave up living,
> Shouted Shah Huseyin then to tears were driven, To taste the ecstasy of that drink came I."

Here we have linguistic evidence of entheogenic ritual in Bektashi Lineage of dervishes. The line in the original Turkish has possible cognates with a mix of Hebrew and Arabic of which the literal meaning might suggest a "heavenly sherbert." The first striking bit of evidence is the act of pounding a plant to produce ecstasy in a ritual context which is consistent with the *soma/haoma* lore which is discussed at length in Wasson, *et al.*, the very word having suggested etymological links meaning, "to pound." The haoma rituals and the mortal and pestle theme seem to be always present on some level of the ceremony from China to Turkey.

While the peony is not psychoactive it is reasonable to suggest that given the rather extensive research of a number of scholars who have described the confounding of this species with a host of other plants, all "active," this could very well indicate either a code word to hide the true nature of the rite from the profane or to further signify a gradual substitution that eventually left the ritual 'watered-down.' The peony seems to be the subject of entheogenic allusions with connections to mandrake or the "aglaophotis" mention by Aelian and Dioscorides which links both together as "dog-dragged" suggesting a further connection with the mandrake with possible celestial implications of the harvest and the Dog Star, Sirius. John Allegro (1970) finds evidence of such connections in Pliny and sundry botanical folk lore, identifying it with the *Amanita muscaria* mushroom through Greek appellations of the sun god and Sumerian linguistic implications of a "capsule of fecundity or a womb." Certainly many of the ancient descriptions of "their" peony are not consistent with the flowery herbaceous plant known today by Pliny's description of capsules full of seeds that are red and black which also makes Syrian rue or harmal another possible candidate that was a likely choice to these opportunistic sects in the situation where the mushroom was scarce or not in season.

Allegro further elaborates at length throughout his controversial book of the further identification ,or in his words, "code" that consists of a language of plants of which the primary species are the peony, mandrake, mushroom *Amanita*, and the added *harmal* (*isfand* of the Prophets) or Syrian rue (Peganum Harmala). The idea of sacrifice and death-like effects of the mandrake along with its human-like root, complement the themes of "redness" that suggest blood. I suggest that the ritual was the subject of a gradual substitution with a keen eye towards appropriate symbolism from human sacrifice to animal sacrifice and entheogens to the eventual substitution of alcohol, the red raki of Turkey. Dr. McElwain also notes that the raki he saw in the Turkish village was of a white color (its usually red), possibly recalling the white haoma discussed by Corbin, and he notes the other name for this raki is "arslan sutu" or lion's milk again increasing the many linguistic connections between the alchemical terminology to the filtering and pounding of the haoma as strained through milk as in the Iranian material. The lion was also the symbol of Ali as the roaring warrior-scholar that was the model Sufi and Shia. The half naked Abdals of Rum have also been described as using botanicals in religious functions such as "certain youth called cuccegler, who carry in certain hand-trays a pulverized herb called *asseral*, which, when eaten, makes one just as merry as if one drunk wine" (Karamustafa 1994).

Allegro's discussion on the mandrake/peony/mushroom centers on evidence that is rather clear from his overall conclusions. The continued support he gives of cognates and allusions across alphabets and cultures with the main focus on the Sumerian, Hebrew and Arabic gives further credence with his scrutiny of Koranic language and the legends of the Assassins.. But this is a precedent for this paper to trace briefly the diverse entheogenic culture that is hidden in different Shia factions, and their use of plants in a ritual context. To trace this theme towards its logical conclusion is beyond the scope of this work, but brief mention of further evidence brought to light by Robert Eisenman (1998) suggests a common language of religious terminology that is so specific that it can be traced in the earliest Hebrew scriptures, especially the apocryphal offerings that are primarily concerned with the elusive sect of the Nasserites. These specific phrasings and epithets can be found as early as Genesis in the descriptions of Noah through the Psalms and into the Gospels. The current research tends to suggest that giving the ensuing inquisitional efforts to formalize Roman doctrine the Gnostic heresies were pushed out into the desserts of Arabia only to come to fruition again in Islam, and through the Shia resistance to the pretended representatives or Caliphs of the Sunni. The pivotal mélange of entheogens, political activism and mystical aspiration conspire against the root of fundamentalism. The ritual described in the poem uses a lyrical recitation in a ceremonial atmosphere in which the candidate's senses are enraptured and seduced by the romance and mystery of a true sacramental cult. His initiation into a larger spiritual context based on spiritual and social justice express the original foundations of Islam as a mission against oppression.

Conclusion

> *The Apple of Khidr*
> At that time I was ignorant of the sciences of realities. And I saw...Khidr..., and he gave me an apple, and I ate a piece of it. Then he said, "Eat all of it, for that is how much of it I ate." And I saw as it were an ocean from the throne to the earth, and I Saw nothing but this; it was like the radiance of the sun. My mouth opened involuntarily, and all of it entered into my mouth. I drank until not a single drop of it remained.
> Sufi Master Ruzbihan Baqli from his *Unveiling of Secrets*

This admittedly speculative hypothesis perhaps begins to define the growing evidence for entheogens in the various related religions of the ancient world. There are numerous gaps in the growing field of ethnobotany and ethnomycology especially with respect to Islamic culture. Certainly any cultures that have a ritual that speaks of some plant/wine/cup that confers immortality offers a clue that entheogens may well have a place in their theology. Alchemical lore is another link as metallurgical guilds were intimately linked with the shamanic arts from the beginning of recorded history and the Islamic material is saturated with the alchemical search for an elixir to such an extant that the fervor passed into Europe. The use of "magical" plants/elixirs/potions/mushrooms in these various cultures suggests that these various mystics either accessed some intact initiatory tradition that conveyed the "ecstatic technology" of entheogens across time or they rediscovered them in the course of consistent and widespread ancient legends.

I end this essay with the words of a female Sufi mystic who seems to speak of the various bright colors of the *A. muscaria* var. *formosa* found at the base of a tree, as they are known to take on caps of bright yellow sometimes. She writes of these other worldly fruits in the walled garden that is paradise and, I would ask, what other fruits grow at the base of a tree than the fruiting mushroom?

> ...I saw, then, in a dream a tree of incomparable
> verdant freshness, beauty and magnitude;
> on this tree three kinds of fruit were growing
> that bore no resemblance to the fruits of this world
> and were plump like a virgin's breast:
> a white fruit, a red fruit and a yellow fruit, shining like
> stars on the green base of the tree...
> Rabia Al Adawiya (c. 714 - 801 A.D.)

Footnotes

1. I have heard in two separate university religious classes suggesting the prophet Muhammad was epileptic though the professors quoted Christopher Hitchens as their source. There is also, of course, a similar prejudice that is subtle in attributing theophany to entheogens, as is the case with the recent article by Shannon (2008) where Moses is mocked as a hippy drug user in the mainstream press.
2. These images can be seen in color in the exquisite book of Seguy (1977) or online http://www.zombietime.com/mohammed_image_archive/islamic_mo_full/ My past co-author Alan Piper and I arrived at the conclusion this image of Buraq as *Amanita muscaria* independently and simultaneously following sometimes identical lines of research. He must be cited as a pioneer in the study Islamic entheogens as well as credited with this contribution.
3. We take the perhaps radical step in taking the Shia as the true representation of Muhammad's Islam, and it seems scholar Henry Corbin agreed. There is even a Shia tradition of how those that supported the Caliphate, i.e. the Meccan hierarchy now nominally Muslim, refused a copy of Imam Ali's Koran in favor for their own "version." There is little love between many Shia and Sunni as recent troubles in Iraq illustrate, and Shia celebrate the demise of Sunni, such as the abhorred Caliph Omar. It must be remembered that the massacre of the Prophet's family at Karbala influenced Shia activities for years to come as most Shia Imams were martyred. I believe this situation reached such proportions that the 6th Imam split the lineage on purpose, even at the risk of sectarian strife to preserve the Hidden Imam,

whose existence is necessary for the existence of the world as the Spiritual Pole, essentially confusing which was the real Imam into such sects as the Alawi/Nusayri and Ismaili who are both prime candidates for the passing of the Grail mythos into Western Culture during the crusades. One must not the sudden appearance of Grail, alchemical cults with severed heads and "widow's son" doctrines in Europe and perhaps the Wasteland motif represents the Arabian Desert. The cup rituals might contain any number of entheogenic substances, such as the dried mushroom that is rehydrated and "pressed" and the liquid "wine" is drunk by the "drinkers of fire" (nusadir). In the course of researching this theory, I must note the Imam Ali is often described as the nephew of the prophet in the literature, even in peer-reviewed Islamic journals, so clearly there are indications that this described the relationship between Muhammad and his cousin/son-in-law, and this is a common theme in much of the Iranian Shia literature.

4. Graves remarks in Food for Centaurs as to Amanita muscaria's "fox-like" color in Palestine. p.273 Nan-e-saghta; peculiarly enough, the Egyptian-Arabic word for mushroom ('aysh-al-ghorab) also translates to "raven's bread". [In the Afdari (Semnani) language of Iran, the name kalagh-nun (crow's bread) is given to an unidentified species of mushroom. (Georg Morgenstierne, "'Mushroom' and 'toadstool' in Indo-Iranian", Bulletin of the School of Oriental and African Studies, University of London 20:451- 457 (1957), pg. 453.) - PGW] The Parzifal Grail myth retain that heavenly bread motiff: Today is Good Friday, and they await there a dove,winging down from Heaven. It always brings a small white water, and leaves it on the stone." Parzifal 827.9 "..the true tale was sent to us..." as oppossed to the false Troyes version Wolfram's stress on the fact the kyot was baptized, as well as multilingual, could mean he was either a Muslim or Jew. Graves (1962) also writes: I learned only last week from an Arabic scholar, that the root-word F.T.R. means, in Arabic, first "toadstool," then "divine rapture," then "sacred pellets of bread." This points to a pre-Islamic hallucinogenic practice of immense age. This wine is described in part of the liturgy as taught by their sects Master, Al-Khasibi who was an intimate with the 6th Imam, with "Oh God, this is your servant 'abd al-nur, a substance you have grace, extolled, and absolutely permitted to your devotees who know you,...less by it with security and protection, and [sound] health and against sickness, and remove us worry and sorrow" and that it is a "substance of fire which God made his His greatest sacrifice and most noble substance" (Bar-Asher et. al. 2002). The Ismaili apparently had a amrita like substance, *ami* associated with a nectar of immortality, that was mixed with the soil of Karbala, where the Prophet's family was massacred (Khan in White 2000).
5. There are many interesting speculations on Templar and Islamic contacts with the Ismaili and perhaps the Alawi as well. The wasteland of the Grail myths are the hot deserts. The "widow's son" symbolism is often associated with military brotherhoods in the knightly romances of Perceval and showing up in Finnish folklore and persisting to at least the Civil War as De Santillana notices in his audacious *Hamlet's Mill*. He relates the curious incident of Gen. Armistead who fell at Picket's Charge in Gettysburg yelling repeatedly to his captors "I am a Son of the Widow" which De Santillana notes "is obviously the password of a secret military brotherhood that his captors did not understand, nor the historian either" and Littleton and Malcor do not attach any importance the recurrence of the phrase. The metallurgical connections with the "Widow's son" may well relate to the master-builder and caster of the Brazen Sea for the Temple, Hiram Abiff who is a "son of a widow" (1 Kings 7:14). I suspect a cult of immortality associated of the "widow's son" being raised from the dead as by Elisha (2 Kings 4:32-37) and Elijah (1 Kings 17:22-24) as well as Jesus (Luke 7:11). Alchemical enigmas can be found that describe the process in terms of mystery of the widow, stone of the widow, or orphans stone. The *Codex Marcianus*, a collection of early Greek/Egyptian alchemical fragments contains a line that links the widow cult with a drug of deathlessness with Isis talking to her son Horus, a widow's son himself, "Now realize the mystery, my son, the drug, the elixir of the widow."

Note to this edition:

1. Samhita Devanagari Accent has been included to Samhita Roman Accent for verses of ṚgVeda according to https://theveda.org.in
2. Latin transcription has been added to Greek words, e.g. ἀμβροσία [*ámvrosía*].
3. Chinese hand calligraphy writings are presented in a form of semistylised computer font.
4. Footnotes numbering changed to continuous form, with each footnote has its individual number.
5. Page references in this version relate to the pages of original edition.

Table of Contents:

PART ONE - SOMA: DIVINE MUSHROOM OF IMMORTALITY
- I. The problem
- II. The Fly-agaric of Eurasia
- III. The Ground Rules of the Search
- IV. Soma Was Not Alcoholic
- V. The Roots, Leaves, Bloosoms, Seed of Soma: Where Are They?
- VI. Soma Grew in the Mountains
- VII. The Two Forms of Soma
- VIII. Epithets and Tropes for Soma in the ṚgVeda
  - A. Introductory
  - B. "Hári" and red
  - C. The bull and soma
  - D. The udder and soma
  - E. The stalk and soma
  - F. Soma's "head"
  - G. Four poetic conceits
    - 1. The single eye
    - 2. Mainstay of the sky
    - 3. The navel
    - 4. The filtres
      - The First Filtre
      - The Third Filtre
  - H. "Tongue of the way"
- IX. Soma and the Fly
- X. Words Used for Soma in the ṚgVeda
- XI. Miscellanea
- XII. Mani, Mushroom, Urine
- XIII. The Marvelous Herb

PART TWO - THE POST-VEDIC HISTORY OF THE SOMA PLANT
- I. The Brāhmaṇas and the &sacute;rauta-sūtras
- II. Later Sanskrit Works
- III. Early European References
- IV. Mid-Nineteenth Century
- V. File Number 118
- VI. The Turn of the Century
- VII. Mukherjee and the *Bhang* Theory
- VIII. Later Researches in the 20th Century

PART THREE - NORTHERN EURASIA AND THE FLY-AGARIC
- I. The Fly-agaric in Siberia: the Testimony of Explorers, Travelers, and Anthropologists
- II. A Far-Reaching Siberian Word-Cluster
  - *1. The Antiquity of Fly-Agaric Inebration*
  - *2. The Distribution of Fly-Agaric Inebration*
  - *3. The 'poŋ' Cluster Among The Indo-Europeans*
- III. Europe and the Fly-Agaric

Epilogue: The Tree of Life and the Marvelous Herb

CITATIONS FROM THE ṚGVEDA
INDEX

PART ONE

SOMA

DIVINE MUSHROOM OF IMMORTALITY

I. The problem

In the second millennium before our Christian era a people who called themselves 'Aryans' swept down from the Northwest into what is now Afghanistan and the Valley of the Indus. They were a warrior people, fighting with horse-drawn chariots; a grain-growing people; a people for whom animal breeding, especially cattle, was of primary importance; finally, a people whose language was Indo-European, the Vedic tongue, the parent of classical Sanskrit, a collateral ancestor of our European languages. They were also heirs to a tribal religion, with an hereditary priesthood, elaborate and sometimes bizarre rituals and sacrifices, a pantheon with a full complement of gods and other supernatural spirits, and a mythology rich with the doings of these deities. Indra, mighty with his thunderbolt, was their chief god, and Agni, the god of fire, also evoked conspicuous homage. There were other gods too numerous to mention here.

Unique among these other gods was Soma. Soma was at the same time a god, a plant, and the juice of that plant. So far as we know now, Soma is the only plant that man has ever deified. (The Mexican Indians seem to regard the hallucinogenic plants, whether mushrooms, *peyotl*, or morning glories, as mediators with god, not as a god. The Nahua - Aztecs and other groups speaking the same tongue - called the mushrooms *teonanáacatl*, 'god's flesh', but the mushrooms do not figure in their pantheon.) In the course of the Soma sacrifice the juice was pounded out with stones on resounding planks and was drunk by the officiating priests. Soma - the three Somas - inspired hymns vibrant with ecstasy, composed over centuries by priests who lived in centers remote from each other. In the end, at an early period in the first millennium before Christ, these hymns were gathered together, and the canon of that text has come down to us intact. Compared with ours, the Vedic civilization was simple, but their verses - the figures of speech with which they embellished their thoughts and feelings, their play with the meanings and sounds of words, the rules of their prosody - were sometimes subtle and sophisticated. Some of the hymns are of so exalted, even delirious, a tenor that the modern reader is led to exclaim: 'This surely was composed under the influence of a divine inebriant'. It takes little perception to sense the difference in tone between the awe-inspired hymns to Soma and the rowdy drinking songs of the West prompted by alcohol.

In the hierarchy of Vedic gods certain others took precedence over Soma, but since Soma was a tangible, visible thing, its inebriating juice to be ingested by the human organism in the course of the ritual, a god come down and manifesting himself to the Aryans, Soma played a singular rôle in the Vedic pantheon. The poets never tire of stressing Soma's sensuous appeal. In appearance it was brilliant, reminding them of the Sun, of Fire, of the rays of the Sun, of the round bowl of the heavenly firmament, 'the back of the sky'. The dried plants were first freshened with water. They were then macerated with stone pestles, and the tawny yellow juice as it came coursing through the conduits of the press was compared, in the hyperbole of the day, with thunder.[1] The priests, after imbibing the juice, seem to have known, for the nonce, the ecstasy of existence in the World of the Immortals. The Divine Element was not just a symbol of a spiritual truth as in the Christian communion: Soma was a miraculous drink that spoke for itself.

A book of 1028 hymns is our sole contemporary source of information about the period it deals with. There is agreement on the text, but many words are of doubtful meaning and doubly so in their allusions that often escape us. They have been preserved for us, both words and melodies, by oral tradition; by achievements of the human memory that have no parallel in other cultures, preserved better than our ancient learning in the

---

1. Parjanya, the god of thunder, was the father of Soma, according to one tradition, ṚgVeda IX 82[3]; Abel Bergaigne, *La Religion Védique*, Vol. I, pp. 172-3.

manuscripts with which our Western scholars are familiar. When a Brahman schooled in the ancient tradition sings us a hymn from the ṚgVeda, with intonation precisely right, there is reason to think that it is as though we were listening to a tape recording 3,000 years old. These hymns, still eliciting the utmost reverence among countless Hindus, constitute the earliest monument in their religious and literary heritage, as well as one of the earliest cultural legacies of our own Indo-European world. As the eminent French Vedist Louis Renou has said, the whole of this immense collection, known as the ṚgVeda, is present *in nuce* in the themes that Soma presents to us.[2]

But what manner of plant was this Soma? No one knows. For twenty-five centuries and more its identity has been lost. The Hindus, probably for the reasons that will emerge as my argument progresses, allowed this authentic Soma to fall into disuse and early on began to resort to sundry substitutes, substitutes that were frankly recognized as such and that to this day are met with in India in their peculiar religious rôle. The West discovered the Sanskrit and Vedic cultures almost two centuries ago. For two centuries we have been absorbing the lessons that India has to teach us, in linguistics, in mythology and philosophy and religion, in literature, art, history, anthropology, archaeology. This difficult assimilation is still going on, though possibly at a slower, more sober pace than in the enthusiasm of the initial discoveries.

But the identity of Soma is as obscure today as two centuries ago, and what is more, this mystery is compounded by what I will call the mystery of the mystery of Soma. When I first embarked on the problem in 1963, I could hardly believe what I found to be the situation. Here is a clear-cut botanical question - a psychotropic plant that calls for identification. The clues should be in the Vedic hymns. True, the poems contain no botanical description such as a scientist would ask for. Those remote singers were no modern botanists. The poet-priests of the ṚgVeda were composing for contemporaries, certainly not for posterity 3,000 years away, and their imagery and terms often elude our understanding, just as our hymns would make hard going for our collateral descendants 3,000 years hence. But the hymns are all shot through with Soma, and 120 of them are entirely devoted to the plant-god. The hymns are not make-believe about a fictitious plant: if ever there was genuine poetry about a genuine plant, here it is. Was it possible that so much could have been written by lyric poets about a plant, over centuries, in many centers of priestly activity, and its identity not be revealed? It was no secret for the poet-priests. How extraordinary it would have been if all of them, numbering scores, perhaps a hundred, had withheld from their verses the revealing descriptive terms, the tell-tale metaphors, that the trained reader today needs to spot the plant! But this did not happen. All that has happened is that no ethno-botanist with an interest in psychotropic plants has applied himself to the examination of the hymns.

The Vedic culture has been primarily a subject for Vedic scholars and secondarily for those scholars who interest themselves in comparative mythology and religion. The specialists in Vedic learning have included a handful of brilliant men, of extraordinary perception, who are assured of a lasting reputation by the works they have left behind. They have been tilling a field, a rich field it is true, in a remote frontier province of the humanities, and they must often have felt that they were leading an isolated existence. The early translations of the ṚgVeda were execrable. Only now, in the annotated translations of the late K. F. Geldner and the late Louis Renou, does a student with no Vedic possess a rendering that permits him to sense some of the nuances of the original.[3] (Certain it is that I, for one, could have done nothing without Renou's translation and commentary.[4]) Throughout the dawn and early morning of Vedic studies, in the 19th century, many cultivated people in the West, not merely Vedic scholars but educated laymen, knew at least what the Soma problem was. More recently, whenever the subject has been broached, scholars and editors have sighed and wearily turned away: the Soma question has dropped into oblivion simply because it has seemed to defy solution. One would have thought that students of religion would have focussed on it, but our contemporary religious thinkers (with notable exceptions) have no sympathy with drugs as a way to religious experience, though accepting a rôle for other external aids such as music, architecture, and liturgy; and (unconsciously of course) many of them are nothing loath to gloss over and ignore the historical rôle of Soma in the higher reaches of our own religious history. Yet it cannot be gainsaid that Vedic culture with Soma unidentified is the play of Hamlet with Hamlet left out. The identification of Soma remains one of the chief desiderata of Vedic studies. That the question continues to be slighted constitutes, as I have said, the mystery of the Soma enigma.

---

[2] *Etudes Védiques et Pāṇinéenes*, E. de Boccard, Editeur, Paris, tome IX, 1961, p. 8.

[3] In *The Soma-Hymns of the ṚgVeda* S. S. Bhawe has begun an excellent translation into English, with a lengthy commentary. Oriental Institute, Baroda, 1957, 1960, 1962. He has published 70 of the hymns to Soma, out of 114 in Maṇḍala IX.

[4] His translation, so far as it had gone before his untimely death in August 1966, had been completed before I had an opportunity to lay before him my thesis, in three long talks that I had with him in Paris and his country house in the Eure, in the spring of that year. He found my thesis *séduisante* and encouraged me to prepare as quickly as possible a full-dress presentation, but naturally he did not commit himself.

There is no sure evidence that in Vedic times Soma was drunk by others than the priests. By a deliberate decision the priests must finally have decided to discontinue the use of the Sacred Plant. That familiarity with the genuine Soma seems to have been confined to the priesthood would make the enforcement of such a decision effective, and the very memory of the plant itself was finally lost. For more than two millennia the hymns to Soma have been sung and revered in the absence of Soma. The record of these intervening centuries is strangely, significantly, silent about the holy herb. In India discussions of such matters were confined to the priestly circles: others were uninformed and uninterested. The priestly compositions that have come down to us show acute concern over the relative merits of various substitutes, but no concern over the plant itself. Moreover, the Hindus traditionally have not been interested in the facts of history, considering them irrelevant when weighed in the balance against the future incarnation of the individual's soul. Brahmans among my friends in India have assured me that the many substitutes for Soma used over the large expanse of the subcontinent and through the ages were always known by the inner circles of the priestly caste to be substitutes. This cannot be proved but must have been a fact. The contrast between the ecstasy of Soma inebriation as sung in the hymns and the effects, often vile, of any of the many substitutes was always too glaring to be ignored.

To the Europeans knowledge about Soma came late. It was not until 1784 that the word itself, spelled *Sōm*, made its début on the European scene, in Charles Wilkins's English translation of the *Bhagavad Gītā*. (The earliest citation for Soma that the Oxford Dictionary gave was 1827.) In the 1830's European scholars finally awoke to the mystery of Soma's identity, but their efforts to solve the problem from that day to this have been singularly futile. They have merely worked over the Brahmanic discussions of the substitutes, apparently under the misapprehension that the original Soma must have closely resembled the substitutes, if it was not in fact one of them. Or they volunteered suggestions pulled out of the air, flouting the ṚgVedic text and Brahmanic practice. In *Part Two* of this book Wendy Doniger O'Flaherty gives the revealing story of this search.

And so in the fullness of time it has fallen on me, a retired banker, to be greatly daring and to submit to the intellectual world a new theory of Soma's identity. As I entered into the extraordinary world of the ṚgVeda, a suspicion gradually came over me, a suspicion that grew into a conviction: I recognized the plant that had enraptured the poets. For this purpose the text of the hymns, the epithets and tropes pertaining to the plant, are abundantly clear. As I went on to the end, as I immersed myself ever deeper in the world of Vedic mythology, further evidence seeming to support my idea kept accumulating. By Jove, I said, this is familiar territory!

At the same time there hovered constantly in my mind's eye the admonitory finger of Tristram Shandy as he warned against the occupational hazard of those who advance hypotheses:

> It is in the nature of a hypothesis when once a man has conceived it, that it assimilates everything to itself, as proper nourishment, and from the first moment of your begetting it, it generally grows stronger by everything you see, hear or understand.

And so, while well aware of the perils that attend my enterprise, I present my case. If I am wrong, how quickly will my proposal be forgotten! If I am right, I claim the privilege of adding a new and exciting chapter to the world's knowledge of the remote past, the proto-history of our own Indo-European culture.

In a word, my belief is that Soma is the Divine Mushroom of Immortality, and that in the early days of our culture, before we made use of reading and writing, when the ṚgVeda was being composed, the prestige of this miraculous mushroom ran by word of mouth far and wide throughout Eurasia, well beyond the regions where it grew and was worshipped.

II. The Fly-agaric of Eurasia

My candidate for the identity of Soma is *Amanita muscaria* (Fr. ex L.) Quél., in English the fly-agaric, the *Fliegenpilz* of the Germans, the *mukhomor* of the Russians, the *fausse oronge* or *tue-mouche* or *crapaudin* of the French, the brilliant red mushroom with white spots familiar in forests and folklore throughout northern Eurasia.

This is the first time that a mushroom has been proposed in the Soma quest.

The fly-agaric is an inebriant but not alcoholic. As far back as our records go, it has been the Sacred Element in the shamanic rites of many tribes of northern Siberia, tribes that are concentrated in the valleys of the Ob and the Yenisei, and then, after an interruption, other tribes in the extreme northeast of Siberia. Apparently some of these tribesmen scarcely knew alcohol until the Russians introduced it in the 16th and 17th centuries, but the fly-agaric had been their precious possession long before then. The available records about its religious rôle are adequate to reveal its main properties but fall short of what we would have them be in the light of the proposal made in this paper. Our earliest eye-witness account of its use is by a Pole, Adam Kamieński, in 1658, among the Ostyak of the Irtysh River (tributary of the Ob), an Ugrian people of the Finno-Ugrian family.[5] Today we know its use is common to the Ostyak and their kin the Vogul, the Ket of the Yenisei Valley, the Samoyed peoples (who together with the Finno-Ugrians make up the Uralic group), and three sister tribes, unrelated linguistically to the others, on the north Pacific Coast, the Chukchi, the Koryak, and the Kamchadal. Responsible observers have reported that the Yukagir, who survive in Siberia in tiny communities near the Arctic Ocean, and the Inari Lapps in Finland, preserve oral traditions of having consumed the fly-agaric in times past, though they no longer do so.

The Russians began their conquest of Siberia at the end of the 16th century and our knowledge of these Siberian tribes virtually starts then. The use of the fly-agaric has been in retreat ever since the arrival of the White Man. It has ceded ground to the vodka of the Russians and, until the Russian Revolution, the fire-water of the western whalers. A more powerful influence has been the aggressive cultural thrust of the Russians, who frown on some of the practices peculiar to the natives. (In a conflict of cultures the stronger one always assumes right away, without examination, that all its ways, its vices as well as its virtues, are incomparably superior.) To the Russian conquest of Siberia, therefore, we owe our knowledge of the use of the fly-agaric and also the approaching end of that use. In the Exhibits we publish *in extenso* the accounts of travellers, linguists, and anthropologists that deal with the fly-agaric in Siberia. There is linguistic and folkloric evidence to indicate that formerly, in proto-history, it was used by some of the Indo-European peoples, as well as the Hungarians.

III. The Ground Rules of the Search

My primary source, the basis of my identification of Soma, is the ṚgVeda, as made accessible to me in the recent annotated translations, to wit, those of Renou, Geldner, and Bhawe.[6] It is certain that the poets of the ṚgVeda knew the original Soma at first hand, and they never strayed from it for long. I invoke later texts and the Avesta only where they help us to know what the ṚgVeda means.

Any suggestion for the identity of Soma must meet the following criteria: 1) Is it in conflict with the ṚgVeda? 2) Does it fit comfortably into such descriptive terms as the ṚgVeda poets apply to Soma, and into the indications as to the source of supply, methods of handling, *etc.*? 3) Does the proposal happily resolve some of the many *cruces* in the ṚgVeda? On all three counts I am hopeful that my suggestion meets the requirements.

---

5. *Vide* Exhibit **[**1**]**, p. 233. Throughout this book the numbers between heavy brackets refer to the Exhibits.
6. I exclude from consideration the latest hymns to have been written, the last to be included in the canon before it was closed. These hymns differ from the others considerably in tone and language, and there is reason to believe that substitutes, which I think had always been occasionally used, had now almost completely replaced Soma in the sacrifice. These hymns are mostly in Maṇḍala X from 85 through 191.

It was only after I had finished my examination of the ṚgVeda text, and after Dr. O'Flaherty had laid before me her paper written at my request on the history of Soma since Vedic times (here published as *Part Two*), that I realized how unorthodox I had been in my approach. It turns out that I was unique. Everyone else, literally everyone, had relied on later sources, sources composed at a time when the original Soma had been superseded by substitutes, and on plants called in various modern vernaculars by names derived from 'Soma'. Or they had had recourse to guesses, without supporting evidence; guesses such as rhubarb, or hashish, or wild grape wine, in disregard of their incompatibility with the ṚgVeda. At a later stage I shall have more to say on this. But here the question of substitutes calls for some discussion.

The Aryans came from the north but no one knows from where. Thomas Burrow made headway on this question when in *The Sanskrit Language*[7] he marshalled the latest linguistic evidence about the prehistory of the Indo-European peoples. The Indo-Iranian branch of the race, before migrating to the areas that they were to conquer, had occupied the marches of the Indo-European domains and had lived in long and intimate contact with a race that spoke proto-Finno-Ugric, with whom they exchanged lexical elements.[8] The words that they borrowed from their Finno-Ugric neighbors do not appear in other Indo-European languages.

If as I believe the Aryans brought down with them from their homeland a cult of the sacred fly-agaric, it must needs follow that their priests had from the start wrestled with the problem of substitutes. The fly-agaric is not always available. Like most species of mushrooms, it does not lend itself to cultivation. The supply is therefore limited and varies with the season and the year. It can be dried and thus preserved: the ṚgVeda speaks on several occasions of water being added to the (presumably dry) Soma, so that it would swell up again.[9] The fly-agaric is a mycorrhizal mushroom: in Eurasia it grows only in an underground relationship with the pines, the firs, and above all the birches. Where these trees are not, neither does the fly-agaric grow. It can be transported, but channels of trade must be set up and maintained. A well organized priesthood would not allow the cult to falter for want of the Sacred Element, and in the Indus Valley settlements, far but not too far from birch and conifer, the use of substitutes, while always regrettable, must have been so common as to arouse no comment. This would make the final abandonment of the fly-agaric easier than if no substitutes had ever been used. Wendy O'Flaherty in her paper on the history of the Soma question has pointed out the consistent association, in early times, of the color red with the substitutes for Soma that were preferred - a significant pointer when the fly-agaric, flaming red, as the original Soma is under consideration. Friends in the Vaidika Saṁ&sacute;odhana Maṇḍala in Poona, where such questions as this are studied, have told me that three criteria governed the choice of substitutes: the plant should be small, it should be leafless, and it should possess fleshy stalks. If these are ancient criteria, it is easy to see how they were suggested by the fly-agaric - small, leafless, with juicy stalk. That the criteria seem arbitrary and permitted the choice of plant substitutes bearing no outward resemblance to the fly-agaric is not incompatible with the sacerdotal habit of mind. The substitute had to be constantly available, and what plant that met this condition could resemble the fly-agaric? In the hot arid regions of northwest India, Afghanistan, and Iran the available species of three botanical genera, Ephedra, Sarcostemma, and Periploca, seemed to meet these requirements with fair success and they came to be widely used in the post-Vedic Soma sacrifice.

There has been an impression in India and elsewhere that Soma was a creeper, *vallī* in Sanskrit. No ṚgVedic authority exists for this term, in fact none in the whole corpus of Vedic literature. But the three genera that I have cited could be construed as *vallī* and therefore I refrain from contending that *vallī* was not used in ṚgVedic times. Indeed in the second half of the Maṇḍala X, in the last batch of hymns to be added before the canon was closed, there is a verse that may refer to such substitutes:

> X 85[3]
> One thinks one drinks Soma because a plant is crushed.
> The Soma that the Brahmans know - that no one drinks.

सोमं॑ मन्यते पपि॒वान्यत्सं॑पिं॒षंत्योष॑धिं	*sómaṃ manyate papivā̆n yát saṃpiṃṣánty óṣadhim*
सोमं॒ यं ब्र॒ह्माणो॑ वि॒दुर्न तस्यां॑श्नाति॒ कश्च॒न	*sómaṃ yám brahmā̆ṇo vidúr ná tásyā&sacute;nāti ká&sacute; caná*

---

7. Faber & Faber, London, 1955, Chap. 1.
8. *Ibid.*, pp. 23-27
9. *Vide, e.g.*, IX 74[2].

(For the convenience of scholars we shall always add the Vedic text of the verses that we quote.) This verse, and the late hymn of which it forms a part, may have been composed at the very moment when the original Soma had already fallen into disuse, when only priests still remembered what it was, and when substitutes were currently accepted as the genuine article.

IV. Soma Was Not Alcoholic

In the West it has been repeatedly suggested that Soma was an alcoholic drink. (The culture of the modern world has long been obsessed with alcohol as the sole inebriant.) This can be denied with assurance. The difference in tone between the bibulous verse of the West and the holy rapture of the Soma hymns will suffice for those of any literary discrimination or psychological insight. But there are criteria other than the literary and the subjective. The stalks were pressed as a liturgical act and before the liturgy was finished the juice was drunk. Three sacramental offerings could be made in one day. Even if we allow for the heat of the summer in the Indus Valley, fermentation could not have advanced far in a religious rite repeated thrice in a day. Moreover, those who know the fermenting process must find it hard, indeed impossible, to imagine anyone, no matter how far removed from our culture, waxing lyrical, even ecstatic, over a drink in active fermentation. It is not as though the Indo-Aryans were unfamiliar with fermented drinks. They had their *súrā*, mentioned several times in the ṚgVeda but without reverential pæans; quite the contrary:

> VII 86[6ab]
> Malice has not been of my own free will, O Varuṇa; it was *súrā*, anger, dice, a muddled head.
>
> न स स्वो दक्षो॑ वरुण॒ ध्रुति॒ः सा सुरा॑ म॒न्युर्वि॒भीद॑को॒ अचि॑त्तिः
>
> *ná sá svó dákṣo varuṇa dhrútiḥ sā́ súrā manyúr vibhī̆dako ácittiḥ*

A mere difference between fermented drinks would not cause the gulf that separates *súrā* from the Soma that inspired the great hymns.

Yet it has been suggested, as will be seen in *Part Two*, that recollections of the mead of their ancestors might have clothed this particular beverage for the Aryans with rich associations entitling it to a superior footing than other fermented drinks. But no one knows whether the ancestors of the Aryans had been drinking mead: many peoples knowing honey do not ferment it. In any case bees with their honey exist in the Indus Valley, and there would have been no reason to give up mead, if indeed it had been Soma, and even less to exchange it for the vile tasting substitutes that took its place. Honey, *mádhu*, is mentioned frequently in the ṚgVeda but mead never. Honey is cited for its sweetness and also is often applied as a metaphor of enhancement to Soma. There is reason to think it was used on occasions to mix with Soma, but the two were never confused. Honey offers no stalks to pound in the course of the liturgy, nor does it ferment in a twinkling.

The most astonishing of candidates for Soma was espoused by Sir Aurel Stein, the explorer-scholar, *viz.*, rhubarb. He had observed it growing wild in the mountains. According to Stein himself, no Indian in recorded history has made a fermented drink of rhubarb, though of course with the addition of sugar or honey the juice lends itself to fermentation. There is no reason to think any Indian ever did so. True, there are stalks to press, but the juice would not ferment and become alcoholic at once. All the rich Soma adjectives and metaphors of the ṚgVeda make odd reading when linked to rhubarb: resplendent, Born of Thunder, Mainstay of the Earth, Navel of the Way, Immortal Principle. Stein must have forgotten either his ṚgVeda or his sense of humour.

In 1921 an Indian advanced the notion that Soma, after all, was nothing but *bhang*, the Indian name for marijuana, *Cannabis sativa*, hemp, hashish. He conveniently ignored the fact that the ṚgVeda placed Soma only on the high mountains, whereas hemp grows everywhere; and that the virtue of Soma lay in the stalks, whereas it is the resin of the unripened pistillate buds of hashish that transport one into the beyond; or, much weaker, the leaves, which are never mentioned in the ṚgVeda. The stalks of hemp are woody.

The Indo-Iranians did not know the distillation process and therefore Soma could not have been a strong drink, *i.e.*, brandy or the distillate of grains. It should be unnecessary to argue this point, but scholars - Indian and Western alike - use the terms loosely, terms properly applicable only to distilled liquor. In IX 107[12] the poet compares Soma with the 'intoxicating one'; Geldner supplies *Branntwein* (brandy) as an example of what he might have meant, and Renou follows his lead with *alcool* (any distilled beverage). I doubt whether they would have made these suggestions had they been alert to the anachronism. V. S. Agrawala in his *India as Known to Pāṇini* seems to mean decanting when he mistakenly says distilling.[10] Dr. O'Flaherty in her account of the Soma search finds it necessary to record many such confusions and ambiguities.

The Orientalist Berthold Laufer wrote, 'Certain it is that distillation was a western invention, and was unknown to the ancient Chinese.'[11] The Dutch scholar R. J. Forbes in his *Short History of the Art of Distillation*[12] concludes that there is no evidence for distilled beverages before the distillation process was discovered and practiced around A. D. 1100 in Italy, probably at Salerno. ('Alcohol' is of Arabic origin but in Arabic it meant something other than what we mean by it.) The making of *aquavitæ* (as it was called for a long time, and still is, in parts of Europe) remained a secret of the alchemists and some monastic establishments for centuries, until the Reformation, when in the course of a decade, in the second quarter of the 16th century, thanks to the dissolution of the monasteries by the Protestants, the 'secret' became common property, and the product, after having changed hands for a king's ransom, sold suddenly dirt cheap. There was no contemporary comment on the social implications of this unanticipated fruit of religious reform.

V. The Roots, Leaves, Bloosoms, Seed of Soma: Where Are They?

In the ṚgVeda (excluding the latter half of Maṇḍala X, last to be admitted to the canon) there is no reference to the root of the Soma plant, nor to its leaves, nor to its blossoms, nor to its seed. In a lengthy anthology of lyric poetry written over centuries in the far flung Valley of the Indus and its tributaries, how odd it is that no poet ever speaks of these conspicuous parts of almost all chlorophyll-bearing plants, not even casually or incidentally. There must have been a conspiracy of silence, laid down perhaps by the dictates of their very religion, but why?

Alternatively, they were speaking of a plant that had neither seed nor blossom nor leaf nor root; *viz*., a mushroom. As for seed, there is positive evidence that Soma was thought to lack seed: Soma was procreated from on high, the Somic germ having been placed by the gods. Soma was divinely engendered:

> IX 83[3d]
> The [gods, those] fathers with a commanding glance, laid the [Somic] germ.
>
> नृचक्ष॑सः पि॒तरो॒ गर्भ॒मा द॑धुः *nṛcákṣasaḥ pitáro gárbhamā́ dadhuḥ*

In a world where farming was already well developed one would expect Soma to be cultivated. A plant with properties so extraordinary would elicit the utmost attention, though owing to its sacred character we would rather expect its growth to be confined to the gardens of the higher priesthood. But the fact is that there is never a mention of its cultivation. Perhaps it did not lend itself to man's efforts to make it grow. To this day the fly-agaric (like almost all other species of mushrooms) refuses to be cultivated. Even in the laboratory it will not sprout.

Note. While our argument in favour of the fly-agaric is founded squarely on the ṚgVeda, there is one verse in the Avesta that seems to speak of the 'trunks' and 'branches' of the sacred plant, and discussion of that verse is in order if only to forestall objections.

The Avesta is the Bible of the religion of Zoroaster (= 'Zarathustra'), a religion that lingers on to this day in the Parsi community centered in Bombay. Tradition has it that most of the Avesta was lost when Alexander the Great overran Iran, but the surviving fragments are still substantial. There is no consensus among scholars on the dates of Zoroaster. Some assign him to about the 10th century B.C., this early date being based on reasonable arguments derived from linguistics and comparative cultural studies. Others prefer to accept the tradition according to which he was living around B. C. 600, the proposed dates being 630-553, or 628-551, or

[12] E. J. Brill, Leiden, 1948, pp. 32, 88-89.

618-541. The *ipsissima verba* of the great Prophet are enshrined in the Avesta, but most of the text is of later date and some of its traditions stem back long before his time. Religiously and linguistically the Avesta and ṚgVeda are siblings. The text of the ṚgVeda is, however, much purer owing to its marvelous preservation through the ages by the disciplined human memory. The Avesta like the ṚgVeda knew an inebriating plant that was the object of worship, and the Avestan 'Haoma' and the Vedic Soma were certainly identical, at least at the start. Three chapters, Yasna 9, 10, and 11, consist of numinous phrases of adoration addressed to Haoma; collectively they are known as the Hōm Yašt. James Darmesteter, who gave us our standard translation of the Avesta, felt sure that the Hōm Yašt had been interpolated late into the text, between B.C. 140 and A. D. 50. One might expect its authority to be impugned by reason of this late date, but an interpolated text may incorporate ancient words and traditions, and precisely this is the situation here, the Hōm Yašt preserving for us in its words and matter some of the truly archaic elements in the Avesta, perhaps antedating Zoroaster himself. Thus it becomes necessary to examine Yasna 10.5, which I give below in the original Iranian dialect peculiar to the Avesta, in Darmesteter's French translation, and in my English rendering of Darmesteter. The speaker is addressing Haoma:

varəδayaŋuha mana vaca	Grandis par ma parole	Grow by my word
vīspə̄sča paiti varəšaǰiš	dans tous tes troncs, dans toutes tes	in all thy trunks, in all thy branches,
vīspə̄sča paiti frasparəγə̄	branches, dans toutes tes tiges	in all thy stems
vīspə̄sča paiti fravāxšə̄	dans tous tes troncs, dans toutes tes	in all thy trunks, in all thy branches,
	branches, dans toutes tes tiges.	in all thy stems.
(In the original text the last three lines are repeated.)	*Darmesteter's rendering.*	*English translation of Darmesteter.*

I have underlined in the Avestan text the three words that Darmesteter renders by 'trunks', 'branches', and 'stems'. The question is how certain are these meanings. (We reproduce on p. 122 [see original ed.] the picture of Haoma that Darmesteter gives us, in what he says is its natural size. It is a leafless plant without 'trunk' or 'branches'.) I shall take up these three words in the inverse order of their appearance in the verse.

3. *fravāxši-*. This word had three meanings or uses: (a) stem, (b) the *membrum virile*, and (c) antler. The prefix *fra-* conveys the idea of forward movement, of growth, thrust, erection. This is lacking in our lifeless 'stem', but how felicitous for our fast-growing mushroom tribe! In many of the world's cultures there is a semantic overlap between 'mushroom' and the *membrum virile*, for obvious reasons; *e.g.*, Greek μύχης [*mýchis*], Japanese *matsutake*. In mycology we use 'stipe' rather than 'stem', but perhaps 'sprout' would convey better the thrust of the original.

2. *frasparəγa-*. According to the lexicons this word meant 'shoot', 'sprout', 'sucker', and again the prefix *fra-* conveys the feel of forward thrust. There seems no warrant for Darmesteter's 'branches', except for the later Pahlavi and Sanskrit translations of the word, which may have been influenced by the current Haoma-substitutes. Darmesteter was presupposing that Haoma was a tree or shrub and translating the word to conform to his presupposition. The meaning and feel of the word closely resembles *fravāxši-*.

1. *varəšaǰi-*. This word presents the Avestan student with difficulties. It occurs only three times, in Yasna 10.5, Yasna 71.9, and Yašt 8.42. The contexts are similar and do not help. The word is compound, noun + verb, *varəša*, 'tree', and *gay*, 'to live'. The grammatical relationship between these two elements is not clear. The suggestion has been made that the word's meaning was 'that which gives life to the tree', whence 'root' seems a viable guess. Bartholomæ suggested this meaning in his famous Old-Iranian Dictionary, but he was not sure as he added a question-mark to the explanation. Darmesteter was following Middle-Iranian traditions when he translated the word as 'trunk', and this meaning was confirmed by H. W. Bailey who at the same time rejected the rendering 'root'. (*Journal of the Royal Asiatic Society of Great Britain and Ireland*, 1934, pp. 507-8.) Bailey's conclusion was based on the Pahlavi translation of the word *varəšaǰi-* by *bun* = 'stalk' or 'trunk', and *advan* = 'stalk', the latter originally meaning 'the upper part of a tree', which rules out 'root'.

The Pahlavi tradition is not a completely reliable guide to the meaning of uncertain terms in the Avesta, but so long as no serious contradiction arises, it may help to make the rendering more probable. If Haoma was a mushroom, the translation must accommodate itself to that fact, and we are relying on the ṚgVeda to establish this. Now if Bailey's 'stalk' be accepted as a possible meaning of *varəšaǰi-*, this is again close to the other two words that we examined before. Here then we have perfect harmony of style. Yasna 10.5 was written in an elevated rhythmic prose by a bard who was addicted to poetic parallelism. We have seen that most of the verse was repeated word for word. We have seen that in the verse that concerns us the second and third substantives virtually duplicate each other. Does it not therefore become a poetic necessity that the first of the triad should be a close synonym? On this assumption and on the assumption that Haoma was a mushroom, I suggest the following translation:

> Swell, (then,) by my word!
> in all thy stalks, and in all thy shoots, and in all thy sprouts.
> in all thy stalks, and in all thy shoots, and in all thy sprouts.

★

For help in dissecting Yasna 10.5 I am indebted and grateful to Dr. Heinrich von Stietencron, of Heidelberg.

VI. Soma Grew in the Mountains

Time and again the ṚgVeda speaks of Soma as hailing from the mountains, from the tops of the mountains, which in the case of the Indo-Aryans meant either the Hindu Kush or the Himalayas:

V 43[4c]
… plant from the mountain, …

मध्वो॒ रसं॑ सु॒गभ॑स्तिर्गि॑रि॒ष्ठां॑	*mádhvo rásaṃ sugábhastir giriṣṭhā́ṃ*

V 85[2d]
… he has placed the Soma on the mountain top.

दि॒वि सूर्यं॑मदधा॒त्सोम॒मद्रौ॑	*diví sū́ryam adadhāt sómam ádrau*

IX 18[1a]
… the Soma seated on the mountain top …

परि॑ सुवा॒नो गि॑रि॒ष्ठाः प॒वित्रे॒ सोमो॑ अक्षाः	*pári suvānó giriṣṭhā́ḥ pavítre sómo akṣāḥ*

IX 46[1b]
… these Somas grown on the mountain top.

क्षरं॑तः पर्व॑ता॒वृधः॑	*kṣárantaḥ parvatāvŕ̥dhaḥ*

IX 62[4a]
… the Soma stalk … seated on the mountain top;

असा॑व्यं॒शुर्मदा॑या॒प्सु दक्षो॑ गिरि॒ष्ठाः	*ásāvy aṃ&sacute;úr mádāyāpsú dákṣo giriṣṭhā́ḥ*

IX 62[15a]
… Born on the mountain top, … the Soma juice is placed for Indra

गि॒रा जा॒त इ॒ह स्तु॒त इंदु॒रिंद्रा॑य धीयते	*girā́ jātá ihá stutá índur índrāya dhīyate*

IX 71[4a]
… [This Soma] … that grows in the mountain …

परि॑ द्यु॒क्षं॑ सह॑सः पर्वता॒वृधं॒	*pári dyukṣáṃ sáhasaḥ parvatāvŕ̥dhaṃ*

IX 82[3b]
… at the navel of the Earth, in the mountains, [Soma] has placed his residence …

नाभा॑ पृथि॒व्या गि॒रिषु॒ क्षयं॑ दधे	*nā́bhā pr̥thivyā́ giríṣu kṣáyaṃ dadhe*

IX 85[10ab]
… In the firmament of heaven the Seers milk … the bull-Soma seated on the mountain top;

दि॒वो नाके॒ मधु॑जिह्वा अस॒श्चतो॑ वे॒ना दु॑हंत्यु॒क्षणं॑ गिरि॒ष्ठां॑	*divó nā́ke mádhujihvā asa&sacute;cáto venā́ duhanty ukṣáṇaṃ giriṣṭhā́m*

IX 87[8a]
... Here is the flow of Soma that is come from within the most distant mountain ...

ए॒षा यंयौ पर॒मादं॒तरद्रेः॒ *eṣā́ yayau paramā́d antár ádreḥ*

IX 95[4b]
... This [Soma], ... [this] stalk, [this] bull seated on the mountain top ...

शुं दुंहंत्यु॒क्षणं गिरि॒ष्ठां *aṃ&sacute;úṃ duhanty ukṣáṇaṃ giriṣṭhā́m*

IX 98[9c]
... This Soma juice, god [himself], sitting on the mountain ...

दे॒वो दैंवी गिरि॒ष्ठा *devó devī giriṣṭhā́*

The poets say that Soma grows high in the mountains. They make a point of this. They never speak of it as growing elsewhere. They must mean what they say. What a useless business it is for us to go chasing in the valleys after rhubarb, honey, hashish, wild Afghan grapes; in hot arid wastes after species of Ephedra, Sarcostemma, Periploca! For the Vedic poet this lofty birthplace was additional testimony to its divine origin, bringing it closer to the celestial sphere, to Indra, to Parjanya. It is unlikely that the poets of the ṚgVeda should have conspired together to attribute a fictitious habitat to Soma.

In Northern Eurasia the birch and conifer grow at sea level. South of the Oxus and in India they are found only at a great height in the mountains, around 8,000 to 16,000 feet. As I have mentioned already, the fly-agaric grows in mycorrhizal relationship with the birch and the conifer. (Centuries later, when the art of writing began to play a rôle in Indian culture, the bark of the Himalayan birch quickly gained renown in Northern India for writing purposes.)

The Indo-Aryans, having conquered only the valleys, did not control the source of their Soma supply. The mountains were still held by their enemies, probably the Dasyus, the hated and despised dark skinned Dasyus. Under the circumstances there could be no ceremony attending the gathering of the sacred Soma, such as had perhaps attended it in the homeland, and such as we know attended the gathering of the hallucinogenic mushrooms of Mexico. All that had been left behind, and now, in Vedic times, a ceremony attended the buying of the holy plant from the natives who came down from the heights where the birch and the conifer grow. In the *&sacute;atapatha Brāhmaṇa* (as well as elsewhere) there is an account, absurd by our standards, of the ceremonial purchase, complete to speckled cane to beat the seller with, wherein a cow of a particular hue of skin and eye is exchanged for the Sacred Element.[13] This barter price for Soma reminds us, curiously, of the high price paid for the fly-agaric by the native tribesmen of the Maritime Provinces of Siberia: they are said to give as much as a reindeer for one fly-agaric, or even two or three reindeer.[14]

VII. The *Two Forms* of Soma

I now come to a crucial argument in my case.

The fly-agaric is unique among the psychotropic plants in one of its properties: it is an inebriant in *Two Forms*.

> *First Form*:
> Taken directly, and by 'directly' I mean by eating the raw mushroom, or by drinking its juice squeezed out and taken neat, or mixed with water, or with water and milk or curds, and perhaps barley in some form, and honey; also mixed with herbs such as *Epilobium* sp.
>
> *Second Form*:
> Taken in the urine of the person who has ingested the fly-agaric in the *First Form*.

---

13. Eggeling translation, Part II, pp. 66 ff.
14. *Vide infra*, **[**11**]**, p. 252.

The *Second Form*, as urine, was first called to the attention of the Western World by a Swedish army officer, Filip Johann von Strahlenberg, after having served 13 years as a captive of the Russians in Siberia. His book, first published in German in Stockholm, appeared in 1730;[15] and an English translation in London in 1736 and again in 1738 under a lengthy title beginning *An Historico-Geographical Description of the North and Eastern Parts of Europe and Asia*. Since then many other travellers and anthropologists have set forth the facts, usually going to extremes in characterizing the practice as revolting, disgusting, filthy, and the like. So far as our records go, none of them has tried the urine, not even the anthropologists, among whom there are usually some who pride themselves on participating to the full in native ways and who consider it their professional duty to do so. In 1798, a Pole, Joseph Kope&cacute;, a literary figure of some standing, tried the mushrooms (but not the urine) and published his remarkable impressions of the experience.[16] That he was ill at the time and running a fever detracts from the value of his testimony.

In the ṚgVeda Soma also has *Two Forms*, expressly so described in IX 66[2,3,5]:

> IX 66[1-2]
> Cleanse thyself, O [thou] to whom all peoples belong, for all wondrous deeds,
> the praiseworthy god, the friend for the friends.
> With those two Forms [*dual, not plural*] which stand facing us,
> O Soma, thou reignest over all things, O Pávamāna!

पव॑स्व विश्वचर्षणे॒ऽभि विश्वा॑नि॒ काव्या॑	*pávasva vi&sacute;vacarṣaṇeʹbhí ví&sacute;vāni kā́viyā*
सखा॒ सखि॑भ्य॒ ईड्य॑ः	*sákhā sákhibhya ī́ḍyaḥ*
ताभ्यां॒ विश्व॑स्य राजसि॒ ये प॑वमान॒ धाम॑नी	*tā́bhyāṃ ví&sacute;vasya rājasi yé pavamāna dhā́manī*
प्र॒ती॒ची सो॑म त॒स्थतु॑ः	*pratīcī́ soma tasthátuḥ*

> IX 66[3]
> The Forms [plural, not dual] that are thine, thou pervadest them,
> O Soma, through and through, O Pávamāna, at the appointed hours,
> O Wonder-worker!

परि॒ धामा॑नि॒ यानि॑ ते॒ त्वं सो॑मासि वि॒श्वत॑ः	*pári dhā́māni yā́ni te tváṃ somāsi vi&sacute;vátaḥ*
पव॑मान ऋ॒तुभि॑ः कवे	*pávamāna ṛtúbhiḥ kave*

> IX 66[5]
> Thy shining rays spread a filtre on the back of heaven, O Soma,
> with [thy] Forms [plural, not dual].[17]

तव॑ शु॒क्रासो॑ अ॒र्चयो॑ दि॒वस्पृ॒ष्ठे वि त॑न्वते	*táva &sacute;ukrā́so arcáyo divás pṛṣṭhé ví tanvate*
प॒वित्र॑ं सोम॒ धाम॑भिः	*pavítraṃ soma dhā́mabhiḥ*

In the Soma sacrifice the *First Form* is drunk by Indra and his charioteer, Vāyu, who are impersonated by high functionaries in the rite. The Vedic commentators, knowing nothing of the fly-agaric, have reached a consensus that the *First Form* is the simple juice of the Soma plant, and the *Second Form* is the juice after it has been mixed with water and with milk or curds. The commentators are agreed on this, the Vedic mythologies are so written, the matter is considered settled.[18]

While in default of any other explanation it is easy to see how this was arrived at, it is unsatisfactory because it flies in the face of the ṚgVeda text. Indra and Vāyu are repeatedly drinking the juice of Soma mixed with milk or curds, and, saving error on my part, they are never in the ṚgVeda drinking juice expressly described as not mixed with anything.

---

15. Philip Johan von Strahlenberg, *Das Nord- und Östliche Theil von Europa und Asia, in so weit solcher das gantze Russische Reich mit Siberien und der grossen Tartary in sich begreiffet*. ... Stockholm, 1730. *Vide* **[**3**]**, p. 234.
16. *Vide* **[**9**]**, pp. 243 ff.
17. Sanskrit and Vedic possess three numbers, singular, dual, and plural. In IX 66[2] the dual number is used speaking of the *Two Forms*. This is natural as the poet faces two vessels containing, one the juice of Soma presumably mixed with milk, *etc.*, the other Soma urine. In verses 3 and 5 he speaks of all Soma's forms, the celestial, the plant, the juice, the Soma urine, and therefore uses the plural.
18. *Vide*, *e.g.*, A. A. Macdonell, *The Vedic Mythology*, London, 1897, pp. 82, 106.

I will cite four instances where Indra and Vāyu drink Soma mixed with milk or curds. The first instance, V 51[4-7], is crucial because there is no mention of curds and the reader might think the poet was speaking of the unmixed juice, exactly as the commentators contend, until suddenly in verse 7, just before the end, it seems that all along the poet took for granted the curds! In the many instances where the poet does not mention the milk or curds, the omission seems accidental. The fly-agaric was often, perhaps usually, dried up when it was used in the sacrifice, and initially it had to be soaked in water, reinflated so to speak. Here are verses V 51[4-7]:

1

V 51[4-7ab]
... Here is the Soma [that] pressed in the vat is poured all around inside the cup, he dear to Indra, to Vāyu.
... O Vāyu, arrive hither for the invitation, accepting it, to share in the oblation! Drink [of the juice] of the pressed stalk, up to [thy full] satisfaction!
... Indra and thou, Vāyu, ye have a right to drink of these pressed [stalks]. Accept them, immaculate ones, for [your full] satisfaction!
... Pressed for Indra, for Vāyu, have been the Soma plants requiring a mixture of curds.

अ॒यं सोम॑श्च॒मू सु॒तोऽम॑त्रे॒ परि॑ षिच्यते	*ayáṃ sóma&sacute; camū́ sutó'matre pári ṣicyate*
प्रि॒य इंद्रा॑य वा॒यवे॑	*priyá índrāya vāyáve*
वाय॒वा या॑हि वी॒तये॑ जुषा॒णो ह॒व्यदा॑तये	*vā́yavā́ yāhi vītáye juṣāṇó havyádātaye*
पिबा॑ सु॒तस्यांध॑सो अ॒भि प्रय॑ः	*píbā sutásyā́ndhaso abhí práyaḥ*
इंद्र॑श्च वायवेषां सु॒ताना॑ं पी॒तिम॑र्हथः	*índra&sacute; ca vāyav eṣāṃ sutā́nāṃ pītím arhathaḥ*
तांजु॑षेथामरे॒पसा॑व॒भि प्रय॑ः	*tā́ñ juṣethām arepásāv abhí práyaḥ*
सु॒ता इंद्रा॑य वा॒यवे॒ सोमा॑सो॒ दध्या॑शिरः	*sutā́ índrāya vāyáve sómāso dádhyā&sacute;iraḥ*

The following three quotations say expressly that Indra and Vāyu drink Soma mixed with milk or curds:

2

IX 11[2]
The Atharvans have mixed milk with thy sweetness, longing for the god, the god [Soma] for the god [Indra].

अ॒भि ते॒ मधु॑ना॒ पयोऽथ॑र्वाणो अशिश्रयुः	*abhí te mádhunā páyó 'tharvāṇo*
दे॒वं दे॒वाय॑ देव॒यु	*a&sacute;i&sacute;rayuḥ devám devā́ya devayú*

IX 11[5-6]
Cleanse the Soma, pressed out by the hand-worked stones; dilute the sweet one in the sweetness [milk or water].
Approach with reverence; mix him with curds, put the Soma juice into Indra.

हस्त॑च्युतेभि॒रद्रि॑भिः सु॒तं सोम॑ं पुनीतन	*hástacyutebhir ádribhiḥ sutáṃ sómaṃ punītana*
मधा॒वा धा॑वता॒ मधु॑	*mádhāv ā́ dhāvatā mádhu*
नम॒सेदुप॑ सीदत द॒ध्नेद॒भि श्री॑णीतन	*námaséd úpa sīdata dadhnéd abhí &sacute;rīṇītana*
इंदु॒मिंद्रे॑ दधातन	*índum índre dadhātana*

3

IX 62[5-6]
The beautiful plant beloved of the gods, [the Soma] washed in the waters, pressed by the masters, the cows season [it] with milk.
Then like drivers [urging] on a horse, they have beautified [the Soma], the juice of liquor for drinking in common, for the Immortal One [Indra].

शु॒भ्रमंधो॑ दे॒ववा॑तम॒प्सु धू॒तो नृभि॑ः सु॒तः	*&sacute;ubhrám ándho devávātam apsú dhūtó nṛ́bhiḥ sutáḥ*
स्वदं॑ति॒ गाव॒ः पयो॑भिः	*svádanti gā́vaḥ páyobhiḥ*
आदी॒मश्वं॒ न हेता॒रोऽशूं॑शुभन्न॒मृता॑य	*ā́d īm á&sacute;vaṃ ná hétāró '&sacute;ū&sacute;ubhann amṛ́tāya*
मध्वो॒ रसं॑ सध॒मादे॑	*mádhvo rásaṃ sadhamā́de*

4

IX 109[15]
All the gods drink this Soma when it has been mixed with milk of cows and pressed by the Officiants.

> IX 109[17-18]
> The prize-winning Soma has flowed, in a thousand drops cleansed by the waters, mixed with the milk of cows.
> O Soma, march ahead toward Indra's bellies, having been held in hand by the Officiants, pressed by the stones!
>
> पिबं॑त्यस्य॒ विश्वे॑ दे॒वासो॒ गोभि॑ः श्री॒तस्य॒ नृभि॑ः सु॒तस्यं॑
> स वा॒ज्यं॑क्षाः स॒हस्रं॑रेता अ॒द्भिर्मृं॑जा॒नो गोभि॑ः श्रीणा॒नः
> प्र सों॑म या॒हींद्रं॑स्य कु॒क्षा नृभि॑र्येमा॒नो अद्रिं॑भिः सु॒तः
>
> *píbanty asya ví&sacute;ve devā̆so góbhiḥ &sacute;rītásya nŕ̥bhiḥ sutásya*
> *sá vājy ákṣāḥ sahásraretā adbhír mr̥jānó góbhiḥ &sacute;rīṇānáḥ*
> *prá soma yāhī̆ndrasya kukṣā̆ nŕ̥bhir yemānó ádribhiḥ sutáḥ*

If then the traditional view of the first and second 'Form' of Soma is to be replaced, what evidence do I adduce in favor of my interpretation?

Only the words of the ṚgVeda. In the hymns to Soma there comes a time when the religious emotion reaches a climax, an intensity of exaltation, that is overwhelming, and that after 3,000 years, in a world of utterly different orientation, even in translation, cannot but move any perceptive reader. These hymns are in Maṇḍala IX, from say 62 through perhaps 97, the mood then tending to ease off. The 74th hymn, in particular, consists of an enumeration of phrases that we have learned by now to recognize when they occur singly, clearly numinous phrases for the contemporary believers, tense phrases piled one on the other, Pelion on Ossa, in portentous sequence, until we suddenly read, at the end of verse 4, a phrase not met with before and not to be met again:

> IX 74[4]
> Soma, storm cloud imbued with life, is milked of ghee, milk. Navel of the Way, Immortal Principle, he sprang into life in the far distance. Acting in concert, those charged with the Office, richly gifted, do full honor to Soma. The swollen men piss the flowing [Soma].
>
> आ॒त्म॒न्वन्नभो॑ दुह्यते घृ॒तं पयं॑ ऋ॒तस्य॒ नाभिं॑र॒मृतं॒ वि जां॑यते
> स॒मी॒ची॒नाः सु॒दानं॑वः प्रीणंति॒ तं नरों॑ हि॒तमवं॑ मेहंति॒ पेरं॑वः
>
> *ātmanván nábho duhyate ghr̥tám páya r̥tásya nā̆bhir amŕ̥taṃ ví jāyate*
> *samīcīnā̆ḥ sudā̆navaḥ prīṇanti táṃ náro hitám áva mehanti péravaḥ*

If the final clause of this verse bears the meaning that I suggest for it, then it alone suffices to prove my case.

Renou renders the final phrase of this verse 4 as follows:

> Les [Maruts] seigneurs à la vessie pleine compissent [le Soma] mis-en-branle.
>
> The [Maruts] lords with full bladders piss [Soma] quick with movement.

Renou had lived with the ṚgVeda text for a lifetime and knew everything that had ever been said by scholars about it. He discerned that the 'swollen' men had full bladders and that they were urinating Soma. But to give meaning to the sentence he introduced the gods of rain, the Maruts. Certainly there are precedents for the clouds' 'urinating' rain. But in this verse and at this point in the hymns the Maruts are out of place. From IX 68 to 109 there are 24 other citations of *nŕ̥* in the plural (men) and in every instance they are the officiants at the sacrifice.'[19] So are they in 74[4]. It is noteworthy that Grassmann translates *nŕ̥* in this verse by 'men serving...' *etc.*, in conformity with his third definition of *nŕ̥*, 'men serving the gods, such as singers and sacrificers'. He does not translate it by his 6th definition, which would include gods. The priests appointed to impersonate Indra and Vāyu, having imbibed the Soma mixed with milk or curds, are now urinating Soma. They in their persons convert Soma into the *Second Form*. When Renou translated this verse, he had never heard of the Siberian use of the fly-agaric. Roger Heim and I apprised him of the facts when we dined with the Renous in the middle of April 1966.

Let us pause for a moment and dwell on a rather odd figure of speech. The blessings of the fertilizing rain are likened to a shower of urine. The storm-clouds fecundate the earth with their urine. Vedic scholars have lived so long with their recalcitrant text, and so close to it, that they remark no longer on an analogy that calls for explanation. Urine is normally something to cast away and turn from, second in this respect only to excrement.

---

19. *Vide* IX 68[4,7]; 72[2,4,5]; 75[3,5]; 78[2]; 80[4(2)]; 86[20,22,34]; 87[1]; 91[2]; 95[1]; 97[5]; 99[8]; 101[3]; 107[16]; 108[15]; 109[8,15,18].

In the Vedic poets the values are reversed and urine is an ennobling metaphor to describe the rain. The values are reversed, I suggest, because the poets in Vedic India were thinking of urine as the carrier of the Divine Inebriant, the bearer of *amṛta*. This would explain the rôle that urine - human and bovine - has played through the centuries as the medico-religious disinfectant of the Indo-Iranian world, the Holy Water of the East.

The words of this hymn IX 74 are redolent with a most holy mystery, the handling of the miraculous Soma planted on the mountain tops by the gods. Those charged with the Office are the Guardians-of-the-Meaning, the Guardians-of-the-Melodies, the Guardians-of-the-Mystery. The Pressing Stones, the woolen Filtre, the mingling of the Soma juice first with water, then with milk or curds in the vessels - all this is set forth clearly. Then the details of the Mystery are hidden from us. This is not in my opinion deliberate. Every party to the proceedings knew every detail. But when an event takes place that stirs people to their depths, a hush naturally falls, a feeling of awe and terror and adoration mingle. They speak in a whisper, as the rubric directs the clergy to do at the climax of the Mass. The details of the Mystery are certainly not to be put into Hymns. Thus we do not know what the dose of the juice was, nor how much water was added, nor how much milk or curds, nor what the effect was. We do not know whether the effect of the *First Form* and the *Second Form* was identical. Chemists say it could well be different, the juice being one thing and the metabolite another. Or it might be the same, the juice developing its marvelous properties only after it has been converted into the metabolite. There is a further possibility. In modern experience the fly-agaric causes nausea. If the agent that provokes vomiting is not the same as the one that leads to ecstasy, the former might be eliminated in the digestive track and the urine be thus freed from this inconvenience. We do not know how the metabolite was taken, whether neat or with water or milk or curds or honey. In the ṚgVeda we are not told who shared in the divine beverage. Afterwards only the priests, or some of them, were privileged to imbibe, but must there not have been a primitive age when others who participated in the rites shared in the drink? We know that centuries later the &sacute;ūdras, the outcastes, were not permitted even to hear the words of the ṚgVeda hymns, so holy were these.

Bhawe calls attention to three passages in the ṚgVeda that seem to him to stress the skill needed in the mixing of the Soma juice.[20] This might refer only to complicated ritualistic gestures and postures that had to be executed with precision. But in his judgement it is more likely that the blending of the ingredients had to be just right. Perhaps there was a secret recipe, the fruit of esoteric experience passed on from one generation of priests to the next. This recipe might be able to reduce or eliminate the initial nausea provoked by the Soma juice.

Let us pause for a moment and consider the probabilities. Some 3,250 years ago the Indo-Aryans living in the Indus Valley were worshipping a plant whose juice, pressed out and drunk immediately, seems to have had astonishing psychic effects, effects comparable to those of our Mexican hallucinogenic mushrooms, comparable but far different. The identity of that plant is not known. Hundreds of poets living over centuries in different centers speak of it in hallowed syllables but without mentioning leaves, roots, blossoms, or seed. Its stalk ('stipe' in mycologists' language) was obviously fleshy. How well these fit a wild mushroom! Nowhere in the thousand hymns is a dimension given of the 'stalk' that is incompatible with the stipe of a mushroom. It grew only high in the mountains. How well this fits the fly-agaric in the latitude of the Indus Valley! The poet says that the priests who have drunk the juice of this mysterious plant urinate the divine drink. In the traditions of Eurasia there is only one plant that supplies a psychotropic metabolite - the fly-agaric. Could any key unlock this combination save the fly-agaric?

If mine is indeed the interpretation to place on the *Second Form* of Soma in the ṚgVeda text, this should not be the only reference to the potable metabolite in Indo-Iranian literature and Parsi traditional practice. In the Avesta there is a verse in a famous Yasna, 48:10, supposed to preserve the very words of the Teacher himself, which has never been satisfactorily explained:

> When wilt thou do away with this urine of drunkenness with which the priests evilly delude [the people] as do the wicked rulers of the provinces in [full] consciousness [of what they do]?
> [*Translation by R. C. Zaehner*. - The text below corresponds to the underlined part of the translation only.]

---

[20] S. S. Bhawe: *The Soma-Hymns of the ṚgVeda*, Part III, p. 176, comment on 70^{8d}; also 47^{1a} and 99^{7a}.

> *Kadā aǰə mūΘrəm ahyā madahyā*...?

The learned commentators, not knowing of the *Second Form* of the Soma of the Iranians (called Haoma), have arbitrarily changed 'urine' to 'excrement' and have puzzled over the meaning. Surely Zoroaster meant what he said: he was excoriating the consumption of urine in the Soma sacrifice. If my interpretation be accepted, there is opened up a promising line of inquiry in Zoroastrian scholarship.

In the vast reaches of the *Mahābhārata*, the classical Indian epic, there occurs one episode - an isolated episode of unknown lineage - that bears with startling clarity on our *Second Form*. It was introduced into the text perhaps a thousand years after the fly-agaric had ceased to be used in the Soma sacrifice, and perhaps the editor did not know its meaning, which only today we are recovering. Here it is, as translated by Wendy O'Flaherty.

> *Mahābhārata*, A&sacute;vamedha Parvan, 14.54.12-35
> *Kṛṣṇa* had offered *Uttañka* a boon, and *Uttañka* said, "I wish to have water whenever I want it." *Kṛṣṇa* said, "When you want anything, think on me," and he went away. Then one day *Uttañka* was thirsty, and he thought on *Kṛṣṇa*, and thereupon he saw a naked, filthy *mātañga* [= *caṇḍāla*, an outcaste hunter], surrounded by a pack of dogs, terrifying, bearing a bow and arrows. And *Uttañka* saw copious streams of water flowing from his lower parts. The *mātañga* smiled and said to *Uttañka*, "Come, *Uttañka*, and accept this water from me. I feel great pity for you, seeing you so overcome by thirst." The sage did not rejoice in that water, and he reviled *Kṛṣṇa* with harsh words. The *mātañga* kept repeating, "Drink!", but the sage was angry and did not drink. Then the hunter vanished with his dogs, and *Uttañka's* mind was troubled; he considered that he had been deceived by *Kṛṣṇa*. Then *Kṛṣṇa* came, bearing his disc and conch, and *Uttañka* said to him, "It was not proper for you to give me such a thing, water in the form of the stream from a *mātañga*." Then *Kṛṣṇa* spoke to *Uttañka* with honeyed words, to console him, saying, 'I gave it to you in such form as was proper, but you did not recognize it. For your sake I said to Indra, "Give the *amṛta* to *Uttañka* in the form of water." Indra said to me, "A mortal should not become immortal; give some other boon to him." He kept repeating this, but I insisted, "Give the *amṛta*." Then he said to me, "If I must give it, I will become a *mātañga* and give the *amṛta* to the noble descendant of *Bhṛgu* [i.e., *Uttañka*]. If he accepts the *amṛta* thus, I will go and give it to him today." As he continued to say, "I will not give it [otherwise]," I agreed to this, and he approached you and offered the *amṛta*. But he took the form of a *caṇḍāla*. But your worth is great, and I will give you what you wished: on whatever days you have a desire for water, the clouds will be full of water then, and they will give water to you, and they will be called *Uttañka*-clouds.' Then the sage was pleased.

Plate I - The Soma of the ṚgVeda

Plate II - The Immortal Hári RV IX 69[5]: With unfading vesture, brilliant, newly clothed, the immortal *hári* wraps himself all around.

We found the first reference to Soma-urine in the ṚgVeda at a point in the liturgy where the proceedings and the religious emotion called for frankness in utterance. This reference did not stand alone in the literatures of Iran and India. There should be yet others in the ṚgVeda itself, perhaps more veiled as befits a holy mystery. I believe there are many such, but for the orderly progress of my argument I will defer their discussion until I reach the third of the three 'filtres'.

VIII. Epithets and Tropes for Soma in the ṚgVeda

Until this very day no poet in the English language has ever sung the supernal beauties of the fly-agaric; nor I believe has any novelist or essayist paid obeisance to this remarkable fruit. The same can be said probably for all the Germanic and Celtic languages. The original 'toadstool' was the fly-agaric, if we judge by the French and Basque languages. In the conservative provinces of France the dialectal name of the fly-agaric is *crapaudin*, 'the toad,' and in the Biscay and Guipuzcoa country the Basques call it by the precise Basque equivalent of the French provincial name, - *amoroto*. In *Mushrooms Russia and History* (Pantheon Books, New York, 1957) my wife V. P. Wasson and I explored the folkloric and linguistic background of the fly-agaric throughout Europe, and showed the deep hold that it exerted at one time on the imagination of the north European peoples. It seemed that a shadow hung over the fly-agaric, an ancestral curse; yes, a tabu. In many West European languages there are childhood ditties dealing with it, but beyond the nursery no one dwells on it except to repudiate it whenever occasion demands. At present I leave to the reader to find his own explanation for this tabu.

In the fall of the year, hard by a birch or pine, one is apt to find the fly-agaric. The season in the temperate zone lasts two or at most three weeks, with the climax coming in the middle week. The fly-agaric emerges as a little white ball, like cotton wool. It swells rapidly and bursts its white garment, the fragments of the envelope remaining as patches on the brilliant red skin underneath. At first the patches almost cover the skin, but as the cap expands they are reduced in relative size and finally are nothing more than islands on the surface. In fact, under certain conditions, especially as a result of rain, they are washed off altogether and the fly-agaric then shines without blemish as a resplendent scarlet mushroom. When the plant is gathered it soon loses its lustre and takes on a rather dull chestnut hue. Such is the dominant fly-agaric in Eurasia and in Washington, Oregon, and British Columbia. There is another variety found commonly in the rest of the United States, a variety that is a brilliant yellow, sometimes with a reddish tinge in the center of the cap. These two varieties are not mutually exclusive: occasionally specimens of each are found in the other's territory, and attention is then drawn to the oddity in mycological journals, perhaps in the miscellaneous notes for amateurs. No one knows what causes these two varieties in different sectors of the temperate zone, nor does anyone know whether the difference extends beyond the coloration and certain morphological features to the chemistry of the plant.[21]

When the fly-agaric is crushed and the juice milked out, the liquor comes forth a tawny yellow. As we shall see, in the ṚgVeda it is sometimes hard to say whether the poet, when he is speaking of Soma, has in mind the plant or the juice. The glowing adjectives of enhancement that he employs could describe either.

Now let us see how the poets of the ṚgVeda describe Soma.

A. Introductory

There are no words in the ṚgVeda that describe Soma as black, or gray, or green, or dark, or blue. All the great Vedic scholars from Burnouf to Renou seem to be in agreement on this.[22]

B. "Hári" and red

Hári is the most common of the colour epithets for Soma in the ṚgVeda. Numerically it far exceeds all the other colour words put together and rivals the epithet 'bull' that the poets never tire of applying to Soma. The word *hári* is cognate with *híraṇya* (golden) in Sanskrit and with χόλος [*chólos*] (gall) and χλωρός [*chlorós*] (yellow) in Greek, and ultimately with the English 'gall' and 'yellow'.

---

21. My division of *A. muscaria* into two varieties will not satisfy the mycologists. Those interested in pursuing this matter should consult Roger Heim: *Un problème à éclaircir: celui de la tue-mouche*, in the *Revue de Mycologie*, Vol. XXX, fasc. 4. 1965, pp. 296 ff.
22. Occasionally in later times *hári* came to include 'green' among its meanings, but this usage seems not to be ṚgVedic, except possibly in the late hymns that we exclude from consideration.

Hári is the precise adjective that one would wish to employ in Vedic to describe the fly-agaric. *Hári* is not only a colour word: the intensity of the colour is also expressed by it. It is dazzling, brilliant, lustrous, resplendent, flaming. In colour it seems to have run from red to light yellow. The mythological horses of the sun-god were *hári*: in this context the word is usually rendered by 'bay' or 'chestnut', but one doubts whether any mundane colour such as bay would describe the steeds of the sun. They are flaming and full of brio. *Hári* is of course a term of enhancement, and by being linked together, Soma and the sun-god's horses are mutually enhanced. How well the breathtaking fly-agaric fits into this picture.

Plate III - Tawny yellow Pávamāna.

Some other colour adjectives are used from time to time for Soma. Thus on one of the many occasions when Soma is called a bull, the bull is 'red,' *vṛ́ṣā &sacute;óṇo* (IX 97[13a]). Others are:

> *aruṇá*: This according to Grassmann means reddish, bright brown, golden-yellow, red, the red of morning.
> *aruṣá*: Again Grassmann: red, fire-colour, applied especially to fire, the sun, lightning, dawn, Soma, *etc*.
> *babhrú*: reddish brown, brown. Monier Williams gives 'tawny'.

The juice of the fly-agaric is tawny yellow. As we have said already, often we do not know whether the plant or the juice is being described. The dried fly-agaric is dull by comparison with the fresh specimen, *babhrú* rather than *hári*.

The poets of the ṚgVeda not only use the same adjective for Soma and the sun-god's horses. They compare Soma directly with the sun. The sun is a shining disc and thus a compelling metaphor for the fly-agaric, as compelling as it is inappropriate for any chlorophyll-bearing plant. Here is a selection of such figures:

I 46[10ab]
Light has come to the plant, a sun equal to gold ...

अभू॑दु भा उ॑ अं॒शवे॒ हिर॑ण्यं॒ प्रति॒ सूर्यः॑
ábhūd u bhā́ u aṃ&sacute;áve híraṇyaṃ práti sū́ryaḥ

I 135[3b]
This [Soma is] thy precise share, accompanied by the rays that are his in common with the sun

तवा॒यं भा॒ग ऋ॒त्वियः॒ सर॑श्मिः॒ सूर्ये॒ सचा॑
távāyáṃ bhāgá ṛtvíyaḥ sára&sacute;miḥ sū́rye sácā

IX 2^{6c}
He [Soma] shines together with the Sun ...

सं सूर्ये॑ण रोचते	*sáṃ sū́ryeṇa rocate*

IX 27^{5ab}
Here he is, racing with the sun, Pávamāna in the sky ...

ए॒ष सूर्ये॑ण हासते॒ पव॑मानो॒ अधि॒ द्यवि॑	*eṣá sū́ryeṇa hāsate pávamāno ádhi dyávi*

IX 28^{5ab}
He [Soma] has made the sun to shine.

ए॒ष सूर्य॑मरोचय॒त्पव॑मानो॒ विच॑र्षणिः	*eṣá sū́ryam arocayat pávamāno vícarṣaṇiḥ*

IX 37^{4bc}
He has made the sun to shine.

पव॑मानो अरोचयत् जा॒मिभिः॒ सूर्यं॑ स॒ह	*pávamāno arocayat jāmíbhiḥ sū́ryaṃ sahá*

IX 61^{8c}
He [Soma] joins forces with the sun's rays.

सं सूर्य॑स्य र॒श्मिभिः॑	*sáṃ sū́ryasya ra&sacute;míbhiḥ*

IX 63^{7ab}
Purify thyself with this stream by which thou [Soma] madest the sun to shine

अ॒या प॑वस्व॒ धार॑या॒ यया॒ सूर्य॒मरो॑चयः	*ayā́ pavasva dhā́rayā yáyā sū́ryam árocayaḥ*

IX 63^{8ab}
Pávamāna has hitched Eta&sacute;a [the sun's steed] to the Sun ...

अयु॑क्त॒ सूर॒ एत॑शं॒ पव॑मानो म॒नावधि॑	*áyukta sū́ra éta&sacute;aṃ pávamāno manā́v ádhi*

IX 64^{7}
[the Soma's flowing liquor] like the rays of the sun.

पव॑मानस्य विश्ववि॒त्प्र ते॒ सर्गा॑ असृक्षत सूर्य॑स्येव॒ न र॒श्मयः॑	*pávamānasya vi&sacute;vavit prá te sárgā asṛkṣata* *sū́ryasyeva ná ra&sacute;máyaḥ*

IX 64^{9c}
thou hast whinneyed like the sun-god.

अक्रां॑दे॒वो न सूर्यः॑	*ákrān devó ná sū́ryaḥ*

IX 71^{9b}
he has clothed himself with the fire-bursts of the sun.

दधि॒ त्विषी॑रधित॒ सूर्य॑स्य	*ádhi tvíṣīr adhita sū́ryasya*

IX 76^{4c}
he who has been cleansed by the sun's ray.

यः सूर्य॒स्यासि॑रेण मृ॒ज्यते॑	*yáḥ sū́ryasyā́sireṇa mṛjyáte*

IX 86^{22d}
thou hast made the sun to mount the sky.

न्नृभि॑र्य॒तः सूर्य॒मारो॑हयो दि॒वि	*nṛ́bhir yatáḥ sū́ryam ā́rohayo diví*

IX 86^{29d}
Thine, O Pávamāna, are the lights, the sun.

तव॒ ज्योतीं॑षि पवमान॒ सूर्यः॑	*táva jyótīṃṣi pavamāna sū́ryaḥ*

IX 86^{32a}
He [Soma] wraps himself all around with the rays of the sun.

स सूर्य॑स्य र॒श्मिभिः॒ परि॑ व्यत॒	*sá sū́ryasya ra&sacute;míbhiḥ pári vyata*

IX 97[31d]
[once] born, thou [Soma] didst fill the sun with rays.

जज्ञा॒नः सूर्यं॑मपिन्वो अ॒र्कैः	*jajñānáḥ sū́ryam apinvo arkáiḥ*

IX 97[33d]
O Soma juice, ... go bellowing to the sun's ray.

क्रंदं॑न्निहि॒ सूर्य॒स्योपं॑ र॒श्मिं	*krándann ihi sū́ryasyópa ra&sacute;mím*

IX 97[41d]
the juice has engendered light for the sun.

जंन॑य॒त्सूर्यें॒ ज्योति॒रिंदुः॑	*'janayat sū́rye jyótir índuḥ*

IX 111[3b]
[The Soma] races against the rays [of the Sun], vehicle beautiful to see, celestial vehicle beautiful to see.

त्सं र॒श्मिभिं॑र्यतते दर्श॒तो रथो॒ दैव्यों॑ दर्श॒तो रथः॑	*sáṃ ra&sacute;míbhir yatate dar&sacute;ató rátho dáivyo dar&sacute;ató ráthaḥ*

For the past century students of the ṚgVeda have been aware of a link that ties Soma to Agni, the god of fire. This tie is intimate and all pervasive, to the point where Bergaigne even went so far as to advance the hypothesis that the two had been interchangeable. Hymns addressed to Soma sometimes call him 'Agni'. (IX 66[19-21]; 67[23-24]) Soma is the child of the thunder-storm. The plant shares its liquid nature with the rain, its brilliance with the lightning (IX 22[2]), and the fire that lightning causes. Its inebriating potency is thought to rival the subtlety of flames. 'Make me to burn like fire started by friction', says the poet, addressing Soma. (VIII 48[6]) Some years ago I gathered together evidence indicating that a peculiar relationship existed in primitive man's mentality between the mushroom world and thunder-storms,[23] extending far beyond the Indo-European tribes but also including them. This relationship exists between Soma and the thunder-storm, and in fact it reaches an intensity no where else found. The flame-like plant, child of the thunder-bolt, possesses inebriating qualities that harmonize with its celestial appearance.

These observations on the colour of Soma may have failed to convey the full impression of radiance that marks Soma throughout the ṚgVeda, radiance without a specific colour linked to it. Take for example this verse:

IX 69[5]
With unfading vesture, brilliant, newly clothed, the immortal *hári* wraps himself all around. By authority he has taken the back [*i.e.*, the vault] of heaven to clothe himself in, a spread-cloth like to a cloud...

अमृं॑क्तेन॒ रुशं॑ता॒ वासं॑सा॒ हरि॒रमं॑त्यों निर्णिजा॒नः परिं॑ व्यत दि॒वस्पृ॒ष्ठं ब॒र्हणां॑ नि॒र्णिजैं॑ कृतोप॒स्तरं॑णं च॒म्वोंर्न॑भ॒स्मयं॑	*ámṛktena rú&sacute;atā vā́sasā hárir ámartyo* *nirṇijānáḥ pári vyata* *divás pṛṣṭhám̐ barháṇā nirṇíje kṛtopastáraṇaṃ* *camvórn abhasmáyam*

In the following verse the poet telescopes the life history of the fly-agaric, and how delicately he does it! For the first time in millennia the verse takes on meaning:

IX 71[2]
Aggressive as a killer of peoples he advances, bellowing with power. He sloughs off the Asurian colour that is his. He abandons his envelope, goes to the rendez-vous with the Father. With what floats he makes continually his vesture-of-grand-occasion.

प्र कृं॑ष्टि॒हेवं॑ शू॒ष एं॑ति॒ रोरुं॑वदसु॒र्यं॑१◌॒॑ वर्णं॒ नि रिं॑णीते अस्य॒ तं जहां॑ति व॒व्रिं पि॒तुरैं॑ति निष्कृ॒तमुं॑प॒प्रुतं॑ कृणुते नि॒र्णिजं॒ तनां॑	*prá kṛṣṭihéva &sacute;ūṣá eti róruvad asuryáṃ várṇaṃ* *ní riṇīte asya tám* *jáhāti vavríṃ pitúr eti niṣkṛtám upaprútaṃ kṛṇute* *nirṇíjaṃ tánā*
